A careful study of these achylia cases reveals many factors at work besides a simple reduction in secretion. In the majority of cases the achylia is secondary. In many there is the vicarious elimination of toxins of extragastric origin. Cultures of the duodenal, pancreatic and biliary secretions are in many instances positive. Not infrequently *Bacillus coli* infections are to be blamed for the trouble, at least, in three cases. Evidences of inflammation of the duodenal mucous membrane can be shown in some instances. A curious paradoxical effect of hydrochloric acid is that very small doses may cure, and overdoses may induce the trouble, the explanation, according to our experiments, being that a small dose delays gastric peristalsis, and a large dose may, by going into the intestinal tract, temporarily induce irritation.

On account of the great number of cases of true achylia without diarrhea that I have seen, it is my belief that in those cases in which it occurs, the probable explanation is that owing to a lack of secretion the small intestinal tract becomes either infected or irritated, in which case rapid peristalsis results in diarrhea. The more pronounced the infection or the irritation, the more pronounced the diarrhea, and the same mechanism that induced achylia may induce hyperirritability of the entire gastro-intestinal tract. This is surely the mechanism in those cases accompanied by frequent mucoid stools. What is the explanation of gastric achylia and gastric hyperperistalsis without diarrhea? The inference to my mind in these cases is, that there has been either a previously existing constipation or that the initial impulse is outweighed by compensatory intestinal digestion. Another point of importance which seems to be lost sight of is the absence of fecal findings of achylia in some bona fide cases of gastric achylia. Here again, in spite of the fact that the specific rôle of gastric digestion is to digest connective tissue, a vicarious digestion occurs in the intestine which leaves in the movement little or no evidence of the gastric achylia. This is the exception rather than the rule, but I have seen some cases in which there are unquestioned evidences of such findings. In other words, there are two broad general groups, a clean-cut achylia and the achylia due to carcinoma, catarrh, gastritis, etc., on the one hand, and over against this group, achylia with a clean-cut diarrhea furnishing evidence alone of perverted gastric function, as contrasted with diarrhea due to a multitude of causes, gastric, hepatic, pancreatic, intestinal. Hydrochloric acid gives the best results in the first group.

The administration of hydrochloric acid in some form is a time honored procedure in the treatment of gastric achylia and in the diarrheas of achylia. Let us see the action of hydrochloric acid in the stomach. Apparently a small amount has little effect on normal digestion, while large excessive amounts, excessive so far as the optimal acidity is concerned, are rapidly neutralized or brought down to optimum by the *verdünnungssaft*, or regurgitant pancreatic secretion. The manner in which hydrochloric acid operates in the achylia stomach may be seen from its use in the following cases:

It is astonishing that in pellagra and in certain forms of purpura there seems to be an achylia, often accompanied by an infected gastritis, which disappears with the gastric infection if the administration of dilute hydrocholic acid is kept up for a sufficiently long time. This is also seen in the subacid infected stomachs of the tuberculous, and especially in those cases of infected diarrhea with achylia. The following method seems to produce good permanent results: Insert the fractional tube and perform lavage, and if need be disinfection; then on the empty stomach introduce at fifteen or thirty minute intervals through the tube from 15 to 20 minims of dilute hydrochloric acid, largely diluted with water, or better still, as I have done, 2 ounces of 0.25 per cent. hydrochloric acid. Keep this up for several hours, and after several treatments (which may be done by the nurse) have the patient eat a full meal, and with the last liquid taken swallow the fractional tube, and then give fractional installations of the 0.25 per cent. artificial acid. A rapid change occurs in many cases, not in all, and in some cases the results in the improvement of appetite and gastric function are remarkable. Another point — in those achylias in which the difficulty in fixing the etiology becomes acute, the administration of parathyroid extract is indicated, on the principle of the stimulatory action of the aparathyroid secretion. I have had two such cases.

CONCLUSIONS

1. Gastric achylia may be due to a number of different etiologic factors inducing in each instance presumably a different type of the disturbance. Instances of psychic, infected, anemic and ductless gland types are given.

2. Studies on achylia seem to indicate that either the entire cycle of gastric digestion, or only certain phases, are affected, which enables us to make a differentiation in types.

3. Achylia may be found in apparently normal persons, and studies in one such case indicate that there is a secretion formed without enzymes or acidity, but probably possessing other properties which as yet are not clear.

4. Artificially delayed secretion and induced achylia, as well as the normal types observed, were all unaccompanied by diarrhea.

5. The injection of partially digested material, or even irritants, into the duodenum fails to induce diarrhea.

6. In the so-called gastrogenous diarrheas the cause is to be found in an associated condition besides achylia, namely, an enteritis most frequently, or if not an enteritis, it is, in all probability, due to a disappearance of the normal protective barrier of the gastric hydrochloric acid. The lack of the acid alone, however, seems insufficient as an explanation of the cause.

7. Implantation of an intestinal infection, or possibly a common cause, inducing both achylia and enteritis, may be responsible.

8. In only one case was it possible to discover an associated pancreatic disturbance.

9. A method of fractional and continuous administration of hydrochloric acid is given as a new method in the treatment of this condition.

1934 Chestnut Street.

ABSTRACT OF DISCUSSION

Dr. Charles D. Aaron, Detroit: When gastric secretion is deficient the first physiologic derangement that follows is in the chemical transformation of the food; the prime requisite, therefore, is the administration of comminuted food which makes the least demand on gastric digestion. Knowing that gastric juice is the only digestive secretion capable of dissolving raw connective tissue, it is advisable to forbid raw, parboiled or smoked meat. Even with adequate mechanical division, the insoluble connective tissue of such food burdens the intestine with waste material, which may either directly or indirectly prove extremely irritating, with consequent diarrhea. In achylia diarrhea, hydrochloric acid, the stimulator of trypsin secretion, is absent; pancreatic digestion is inadequate and the feces are apt to contain microscopic meat remnants, not connective tissue only. Therefore, meat should be given in restricted quantities. Vegetables and fruit should also be given sparingly, on account of the irritation likely to follow from the cellulose they contain. It is necessary to boil thoroughly all vegetable food.

As to the disturbances from the intestinal indigestion, there is practically only the diarrhea to be considered, the ultimate cause of which is, in all probability, an insufficient digestion of the cellulose. It follows that in diarrhea the dominant principle should be complete elimination of cellulose from the food. According to my experience, the articles of diet which can be ingested with increasingly less and less impunity in this condition are, in the order named, sugar, finest wheat meal, rice meal, arrowroot, grits, zwieback or toast, sago, spaghetti, rice, white bread. Potato starch is always poorly assimilated, and mashed potatoes agree with scarcely any of these patients. The artificial carbohydrates constitute a very suitable article of diet, the starch they contain being more or less dextrinized. As long as putrefaction of the intestinal contents continues, sweet milk is unsuitable and apt to cause diarrhea.

Dr. Albert F. R. Andresen, Brooklyn: At the Brooklyn Hospital we have made fractional examination of gastric contents by the Rehfuss method in about 500 cases of gastro-intestinal disorders. Of these cases, fifty-two showed a true achylia, including eight carcinoma cases. The "false achylias," that is, cases showing no free hydrochloric acid at the three-quarter hour point, but a subsequent rise, numbered twenty-five, so that we should have had nearly 50 per cent. more cases if only the regular single removal at the three-quarter hour interval had been made. Some of these "false" cases showed a free hydrochloric acid index as high as 70 during the latter part of the two-hour period, being really delayed hyperacidities. All true achylias showed a marked hypermotility, the stomach being empty at or before the two-hour point in over 80 per cent. of my cases.

Diarrhea occurred in 24 per cent. of my fifty-two cases, constipation in 67 per cent., regular bowels in 9 per cent. The diarrhea cases were nearly all associated with infections elsewhere, and were probably infectious in origin. I feel that achylia gastrica itself is merely a name given to a symptom of an infection of the gastric mucosa, an endogastritis, as it were, secondary to a focus of infection elsewhere in the body. I found blood in the stomach contents in over 90 per cent. of my cases, and in the stools in 67 per cent. Vomiting occurred in 38 per cent. The loss of weight averaged over 30 pounds.

As for treatment, it is remarkable how quickly the use of dilute hydrochloric acid, even in small doses, will affect certain symptoms, notably the diarrhea and the epigastric pain. I think this effect is distinct from the benefit to be obtained from the other, and perhaps more important, part of the treatment, the dietetic, which has already been so ably discussed. The occasional diarrhea following the feeding of milk can usually be overcome by acidifying the milk—a teaspoonful of dilute hydrochloric acid to a glass of milk, added just before drinking.

Dr. Max Einhorn, New York: A great many physicians think or speak of diarrhea as being associated with achylia, but I always maintain that the larger group of cases is accompanied by constipation. We have those cases also in which diarrhea alternates with constipation, and again a group in which diarrhea is present. Achylia can also exist together with other conditions in organisms which do not manifest any symptoms at all, with the patient in apparent perfect health. In one of my first papers on the subject I mentioned the case of a patient who had had this condition for forty years and did not know he had any stomach trouble, nor did I, and I discovered the achylia only accidentally.

With regard to the division into achylia and spurious achylia, I think those cases in which some secretion appears later are not real achylia but cases of subacidity in which a little ferment is found that ultimately increases. Dr. Rehfuss mentioned that we may have a condition in which no gastric ferments can be detected—no pepsin, no hydrochloric acid—and still there may be something oozing from the mechanism. I would subscribe to that. In fact, I have described such a condition (hydrorrhoea gastrica), finding it principally in instances of cirrhosis of the liver accompanied by pyloric obstruction. I took this to mean that there is too much fluid in the blood vessels and a kind of pressure relief by exudation through the gastric walls. That may be a different type, but I am sure in ordinary achylia there may be something oozing from the mucous membrane, although the glands are not active. This is a matter difficult to decide.

In regard to the treatment, Ewald and a great many other clinicians lay much stress on the value of hydrochloric acid in the treatment of achylia, but personally I do not ascribe so much importance to that medication. In the majority of my patients with true achylia, where there is no secretion, I may give it for a short while, but on the whole they go along for years without a drop of hydrochloric acid, and just as well.

Dr. Louis Lefrak, New York: The term achylia gastrica is a comparatively recent addition to medical nomenclature. Friedenwald, in Osler's "Modern Medicine," gives Einhorn the credit of having been the first to use the term in conditions in which there was an absence of gastric secretion. I believe that, with the exception of secondary achylias, the condition in a majority of cases is simply one of chronic gastritis with atrophy of the secretory glands. This contention is borne out by the following observations made in the gastro-intestinal clinic with which I am connected and, to a lesser extent, in my private practice: It usually occurs in patients over 30; its incidence is almost equal in both sexes; often there is no other evidence of neurasthenia. This opinion is also held by Dr. Cheney in his paper published in The Journal, May 19, 1917.

I believe if we had a clearer conception of its pathology, achylia gastrica would be classed as a symptom of chronic gastritis instead of a clinical entity; that is, as an organic disease instead of a functional disease. It can readily be seen that if this statement has any value it must affect the treatment considerably.

Dr. Seymour Basch, New York: Achylia gastrica has always been one of the unsolved problems in gastro-enterology and I fear it will remain so for some time. This is illustrated by the fact that patients who come to us for other conditions, feeling well and looking well, on analysis are discovered to have an absence of hydrochloric acid. On the other hand, we have patients coming to us with all the clinical signs, often showing associated diarrhea with loss of weight, etc., and they are treated for a while and then leave our hands; years afterward we find that they are well without any treatment whatever. There are deeper problems than those which appear on the surface. One has been brought out and solved by Dr. Rehfuss in dividing achylia into two groups—psychic and chemical. I think that is an important addition. Another point which will have to be solved is with reference to the protective fluids of the stomach in achylia. To illustrate: In hyperacidity we have antipepsin. Perhaps there is some protective ferment or fluid which protects the patients in an unknown way. It is only by definite study that we will be enabled to solve some of these problems.

The clinical value of achylia studies comes out in the differentiation between true achylia and achylia which is associated with other conditions such as carcinoma, or achylia as a reflex condition, etc., where we cannot talk of achylia merely as a clinical entity, but as a complication, as Dr. Rehfuss has said. I failed to hear any mention made in this differentiation between true achylia and achylia associated with neoplasms. Some years ago Dr. Steel tabulated a number of cases and found that in patients with chronic appendicitis, where undigested meat had been found in the stools, the intestinal condition cleared up entirely after operation. I myself have seen a case of achylia associated with hernia in which, also, the achylia cleared up after operation.

Another form, which is rare and often overlooked, has been pointed out, and that is the achylia associated with benign tumors of the stomach. We are apt to think that this is infrequent, but investigation will show that it is not as infrequent as we believe.

Dr. J. W. Weinstein, New York: Dr. Rehfuss omitted to point out that achylia gastrica is often not achylia gastrica, but is often chronic atrophic gastritis; it is often a carcinoma of the stomach; in the more exceptional cases, perhaps, achylia gastrica has a neurotic basis; and then there is achylia gastrica as such.

Dr. Rehfuss spoke of spurious achylia. I find that spurious achylia is very common in the practice of those whose experience is limited. Of course, that remark does not refer to Dr. Rehfuss, whose experience is extensive. I find that my assistants at the clinic, before they have had a large experience, meet with a large number of cases of achylia, but that after their experience has been augmented, the number of achylia cases becomes much smaller. What is the reason? It is this: There is a certain time only when stomach contents should be extracted. I am not speaking of the fractional method which Dr. Rehfuss is using, but that method which the majority of the profession is using. It is necessary to take out the stomach contents at the height of digestion; for the ordinary test meal it is fifty minutes. It is also necessary that the patient take a full meal, because if the patient takes but one half or one quarter of the meal, one is likely to get achylia, since at the end of digestion the secretion declines. Moreover, we have other factors to consider—the secretion of the saliva which neutralizes the acid, and also regurgitation of intestinal juice.

As to the treatment, I agree with Dr. Einhorn that treatment by means of acid is not very successful. It is true that in some cases it is very successful, and it is worth while in every case to give the patient some hydrochloric acid. I make it my rule always, however, to tell patients that this is only an experiment, that it may decidedly disagree with them, for it is very unpleasant after going through tests and examinations and giving them diet and medication to hear patients say that they feel much worse than they ever felt before. It is unquestionably common to hear this from patients if hydrochloric acid is administered. I find it is especially contraindicated and not tolerated in those cases in which there is true achylia, where there is no secretion at all. It seems that the mucous membrane acquires a hyperesthesia toward hydrochloric acid, and they feel worse than ever if it is administered in these cases.

Dr. I. O. Palefski, New York: I agree with Dr. Einhorn that the so-called "spurious achylia" mentioned by Dr. Rehfuss in his paper is probably one of the forms of subacidity which tardily respond to stimulation by an Ewald test meal. The presence or absence of mucus should serve as a basis of differentiation between these conditions and achylia. The trained eye will readily recognize the existence of achylia by mere inspection of the characteristic two-layer test meal, the rapidly settling lower layer consisting of the undigested food and the superimposed, clear, colorless liquid layer, devoid of mucus and free acid. In pyloric regurgitation caused by transient relaxation of the pylorus, the regurgitated alkaline duodenal contents will not only neutralize the acids but will also dissolve the mucus in the gastric contents. It is impossible, therefore, to differentiate between this condition and achylia unless the examination be prolonged, as Dr. Rehfuss did, or, even better, be repeated on the following day, when normal gastric findings may be obtained.

I rely on clinical observation in declaring that the association of achylia and chronic pancreatitis is not an infrequent occurrence. This should be suspected in achylia with a history of loss of weight and the presence of anemia. Dr. Aaron justly emphasized the value of Schmidt's functional test diet as a control of pancreatic digestive power in achylia. Owing to the disturbing elements present in the examination of feces, however, the quantitative analysis of the pancreatic enzymes in the fresh duodenal contents is preferable.

Clinically, one readily observes the beneficial effects of hydrochloric acid in achylia. This I am inclined to attribute, in no small degree, to its controling effect on the pylorus. The stomach empties rapidly in achylia, due to the relaxation of the pylorus. This allows insufficiently liquefied and improperly subdivided food to enter the intestines, which serves as an intestinal irritant and causes abdominal cramps and diarrhea. Conversely, the administration of hydrochloric acid increases the tonicity of the pylorus, thus prolonging the stay of the ingested food in the stomach, where it undergoes a more thorough subdivision prior to its entrance into the intestines.

Dr. Harris Weinstein, New York: I have no doubt that in time Dr. Rehfuss may clear up various etiologic factors of achylia. We know that achylia may be either functional or organic. Functional achylia appears in conditions in which all the functions of the system are more or less depressed, as in chronic infectious diseases, anemias, particularly pernicious anemia, circulatory disturbances, nephritis, etc. In tuberculosis we find that the disease induces more or less progressive reduction in both the motor and secretory functions of the stomach. Dr. Rehfuss analyzes these conditions, and he may be able to throw more light on them in time, particularly as to the effect of the hormonopoietic system on the nervous system and its resulting effect on the secretory condition of the stomach.

As to the effect of hydrochloric acid in achylia, nobody believes that a small quantity, or even large quantities, of hydrochloric acid can have any telling effect on digestion. I do not believe anybody gives it with that aim. We give it as an activator of the pancreatic pro-enzymes, and in this manner it probably takes the strain off the intestines in so far as it causes better digestion in the intestine. Achylia may run along (in fact, 40 per cent. of the cases do run along) with no symptoms at all, and achylia, if it is not due to chronic gastritis or a malignant condition of the stomach, does not become evident unless pancreatic digestion breaks down. Dr. Rehfuss injected some irritating substance into the duodenum and did not get any diarrhea. We must not forget that achylia does not mean the introduction of undigested food into the intestine one, two or three times; it means that this has been going on for years, and sooner or later the mucosa will become irritated and enterocolitis will result.

Dr. B. B. Vincent Lyon, Philadelphia: In my opinion the greatest contribution that Dr. Rehfuss has made is the differentiation between true chemical achylia and spurious achylia. I do not believe it is possible for us to determine cases of spurious achylia by any other than the fractional method. It is fallacious to select any single point of time for test meal extraction—be it fifty, sixty or seventy-five minutes—and limit the classification of achylia as determined by that one point. There is no doubt that in true chemical achylia we are fundamentally dealing with a progressive atrophy of the mucous membrane, and this atrophy is probably complete, inasmuch as few of us have seen the return of true gastric secretion. In some of the cases there has been a moderate and slow increase in the return of the juices, but in such cases we are dealing with an incomplete gastritis in which some cells are still capable of functioning.

The chief differential point to determine is the presence or absence of pro-enzymes. If we can determine the absence of pro-enzymes, we must conclude that we are dealing with gastric cells whose function has been pathologically destroyed.

In the treatment of the achylias it seems to me it is much more important to preserve the efficiency of the pancreatic ferments. If the intestinal digestants fail in compensation, the patient develops diarrhea. If the pancreatic ferments are studied by duodenal intubation, the proportional amounts of pancreatic ferments can be determined by the Crohn method and pancreatic substitution therapy instituted, and this may be very much more important than the administration of hydrochloric acid.

Dr. Martin E. Rehfuss, Philadelphia: I realize that in fifteen minutes allotted to me it was not possible to do justice to the question of achylia gastrica. The question I tried to investigate most was the etiology of these cases. I have a very large number of so-called cases of achylia, but I maintain that careful study by careful methods will show that there is a so-called spurious type, a type in which delayed gastric secretion is frequent. At the hospital we have made a little over 15,000 examinations on all sorts of stomachs and have been able to note the effect of various foodstuffs under normal conditions. I consider this a rather important point from the gastric standpoint. We investigated a great many of these conditions and found various forms of achylia. I have said comparatively nothing regarding the so-called malignant achylia. One can hardly go into the wards of the Jefferson Hospital without finding at least one case, and at times several cases. I am speaking of those cases which are mostly functional. In looking over these cases we find, as Dr. Einhorn has said, that diarrhea when present is secondary and plays a minor rôle. Over 50 per cent. of our patients were constipated, and the remainder was distributed among patients who had attacks of diarrhea and of dietetic intoxication. The point made is that the cases are subject to careful analysis. I have found only one case in which on duodenal intubation there was true insufficiency of the pancreas. I have in my paper a list of the various types of bowel movements, but the interesting thing is that a careful study of the mechanism of the bowel movements will demonstrate that they are very different, depending on the different factors at work.

The question of benign and malignant achylia ought to be taken up. I wrote a paper regarding the protein content and material in the stomach in benign and malignant achylia. In the latter I found that there was a very different curve running throughout the gastric cycle; in other words, the increase of protein was brought out.

Duty of Maintaining Health.—Keeping healthy is a part of doing "your bit."—Connecticut *Health Bulletin.*

VESICAL DIVERTICULUM

REPORT OF TWO CASES, WITH REMARKS ON OPERATIVE TECHNIC *

BRANSFORD LEWIS, M.D., B.Sc.
Fellow of the American College of Surgeons; Professor of Genito-Urinary Surgery, St. Louis University, School of Medicine
AND
NEIL S. MOORE, M.D.
ST. LOUIS

Vesical diverticula represent exaggerated sacculations of the mucous membrane, connected with the general bladder cavity by an opening of variable size. Some writers have expressed the belief that practically all cases are congenital, but latterly there has been a reaction from this position, with a tendency to ascribe most cases to acquired conditions (Lower[1]), the result of obstruction located mainly at the vesical neck.

In the two cases reported herewith the causative relation between obstruction at the vesical neck and the diverticula was plainly shown in the well defined ring of fibrous tissue that surrounded the neck of each bladder; while in the few other cases observed by us, but without being brought to operation, an obstruction was always demonstrable, so that our own inclination is to share belief in the predominance of acquired over the congenital origin of this malady.

Englisch[2] based a differentiation between congenital and acquired diverticula on the question as to whether their walls possessed muscular bands or not, asserting that those with muscular tissue were congenital; those without were acquired.

This classification, however, has been difficult of proof and has not been supported by all writers. Thomas,[3] in reviewing twenty cases of diverticulum observed in the Mayo Clinic, asserts that they were incapable of making such a classification. But whether congenital or acquired, it is probable that some obstruction has been present at some time in every case, either during intra-uterine life or subsequently.

Rokitansky's[4] declaration that diverticula were found only in bladders having hypertrophied walls was not borne out by the two cases herewith reported. In one the bladder wall was as thin as paper and broke down precipitately under gentle manipulation.

Diverticula are single or multiple, and vary considerably in their size as compared with the bladder cavity. Sometimes they are as large as, or even larger than, the bladder cavity.

Whether congenital or acquired, the walls of diverticula are supplied with so little muscular structure that they are inert and incapable of contributing to the evacuation of the organ. Urine contained in them tends to stagnate and undergo infection and decomposition, becoming then highly irritating and a frequent source of urinary sepsis, with chills, fever and other sequels.

No form of treatment has been able to supply this deficiency of muscular activity or contractility to the sacculation and hence, until a definite plan for their removal was finally evolved, operative treatment was a failure. Dilating or incising their orifice, for increasing the ease of communication between the main cavity and the accessory one, failed for the same reason.

Marked developments in respect to both diagnosis and treatment within the past half-dozen years have inspired the greatly added interest, as well as the more frequent recognition of this very imposing and portentous malady. Previous to 1912, although recognized in the abstract, vesical diverticulum was looked on in the light of a surgical curiosity, rather than a pathologic condition subject to remedial measures. Since then conditions have materially changed, and many persons the subject of diverticula and their attendant evils have been reclaimed from a very miserable existence to comfortable living. This satisfactory development has been due to progress in the technic of diagnosis and of operative therapy.

In addition to wider recognition of diverticula through the better and more universal practice of cystoscopy latterly in vogue, the taking of roentgenograms of the suspected bladder filled with a fluid opaque to the roentgen ray has proved a wonderful service. This has permitted ready identification of the sacculation, its location, size and number, if multiple, and has afforded evidence on which to base a conclusion as to the advisability and mode of surgical attack.

But more important still has been the simplifying of the surgical operative procedure by adopting measures to convert the more or less elusive and intangible diverticulum into a solid tumor by inserting into it the rubber elastic bag of Lerche,[5] or packing the sack with strips of gauze, as suggested by Cabot[6] and popularized by Lower in his several very valuable contributions on the subject. This feature of the technic has proved so valuable that much of the advance in this work must be ascribed to it.

The ureter, occasionally injured or severed during the operation, has been protected or repaired, as the case might be, by measures promoting that objective, such as preliminary ureteral catheterization, as advised by Beer, or the use of valve-flap transplantation, as suggested by Young.

Experience has proved the propriety of keeping the operation extraperitoneal, stripping the peritoneal membrane from the bladder wall as far as necessary to give access to the sac; and of sewing up the bladder wall tightly, using a retained catheter in the urethra for urinary drainage. It has been the habit of operators to drain the pocket from which the diverticulum has been removed by a rubber tube or cigaret drain passed through the abdominal wound that was made to gain access to the bladder; but we have used with entire satisfaction, and it is believed with distinct advantage, a stab-wound cigaret drain into the extraperitoneal space, thus avoiding contact with the main wound edges and promoting their early and complete union.

The indwelling urethral catheter is preferred by us over the method of repeated catheterization for emptying the bladder following the operation. There are few patients who cannot easily and comfortably wear a soft rubber catheter for this purpose for the few days required to secure union of the wound area, notwithstanding a widely prevalent impression to the contrary. Many patients can wear urethral catheters for weeks or months, without serious discomfort.

This measure is often one of the most efficient for preparing the patient for operation, affording gratify-

ing if temporary relief from retention and sepsis, and contributing much to the restoration of functional activity to the organs most involved.

It goes without saying that all preparatory measures now recognized as essential to the attainment of success in major genito-urinary operations should be provided.

The steps of diverticulum resection as carried out by us are as follows:

1. The ureter of the affected side is catheterized, the bladder being left filled with fluid and a rubber catheter in the bladder.
2. Epicystotomy is done, the bladder wall being attached to the abdominal wall on each side, but especially on the side opposite the diverticulum.
3. The diverticulum is packed with gauze.
4. The peritoneum is stripped off.
5. If the ureter has been cut, its end is opened and it is drawn through a button-hole into the bladder and attached.
6. The hole in the bladder wall from which the diverticulum was excised is sewed up. The stitches are reinforced, chromic catgut being employed.
7. Operation is performed on the prostate or neck of the bladder if necessary.
8. Stab wound drainage is used, with a cigaret drain.
9. The retained urethral catheter is inserted.
10. The anterior wall of the bladder is sutured and closed completely, with catgut.
11. The abdominal wound is sutured with catgut and silkworm gut.

The clinical pictures, as well as the method of securing permanent relief, are fairly well illustrated in the histories of two cases herewith reported.

REPORT OF CASES

Case 1.—A man, aged 51, railroad engineer, American, married, had no history of any venereal diseases. The patient's health had been good up to the beginning of the present illness, which occurred Nov. 4, 1916. Up to this time he had been in the habit of urinating only four or five times daily and did not void at night. November 4, without recognizable cause, he began to have severe burning with urination and undue frequency. There was no blood in the urine at that time, but with a continuance of the irritative symptoms he noticed that blood appeared ten days later (about November 14). The blood was mixed with the urine and did not precede or follow the act. With remissions there was a continuation of these symptoms until his arrival at the Frisco Hospital, in the service of Dr. G. W. Cale, Nov. 25, 1916. His general condition then seemed very poor; he was thin and looked run down. There was excessive frequency of urination day and night, together with much pain each time; both urines were cloudy with pus and blood appearing microscopically. There was colon bacillus infection. Cystoscopy, November 29, showed widely diffused cystitis of marked intensity. The well defined orifice of a diverticulum was located in the left posterolateral segment of the bladder, anterior (distal) to the ureteral ridge. The orifice appeared about the size of a dime. The bottom of the diverticulum was not visible. The ureter catheter inserted into it reappeared at the orifice after 3 or 4 inches of catheter were used. No stone was observed. The ureteral orifice was not visible on this side. Roentgenograms of the bladder filled with thorium solution showed a definite sacculation about the size of an apple, posteriorly and to the left of the bladder, attached to it by a narrow neck.

Operation was performed Dec. 9, 1916, with the assistance of Drs. Moore, Woolsey and Smith. Anesthesia was given by Dr. Wood. This operation followed ten days after preparatory treatment, consisting of frequent irrigations through a retained catheter, rest, internal antisepsis, etc. With the bladder fairly well filled and the patient in the semi-Trendelenberg posture, an incision was made in the midline of the abdomen until the anterior wall of the bladder was reached. The peritoneum was stripped from the bladder, partly by a dissection with scissors but more by the gauze-covered finger. It was noticed that the whole anterior wall of the bladder, particularly toward the left, was very thin, at some parts as thin as paper; which explained the fact that when an attempt was made to place stay-sutures in the anterior wall, the wall suddenly broke down and opened up the bladder cavity. After the field had been dried, several catgut sutures were placed in the right wall of the bladder, attaching it to the abdominal wall on that side. The left wall was controlled by a stay-suture left loose and was serviceable later as a guide. Inspection revealed a spacious bladder cavity with ureteral openings plainly visible; and slightly anterior to the left ureteral opening could be seen the orifice of the diverticulum, corresponding to the observation made by cystoscopy. Narrow strips of gauze were then stuffed into the diverticulum until it was quite full. This maneuver was facilitated by grasping the margins of the orifice with forceps and holding them well up, thus permitting a much larger quantity of gauze to be inserted than would otherwise have been the case. The diverticulum was in this way converted into a solid tumor about the size of a pear, outside of the bladder. The peritoneum was then stripped from the left bladder wall and from the tumor. The earlier part of this maneuver was easy, but became more difficult later, as the diverticulum was situated so low down in the pelvis and behind the bladder that it became less accessible. Part of the separation had to be made with scissors. The pedicle was found to be as thick as a finger. With one forefinger through this neck for guidance it was excised with scissors after the tumor had been well lifted out of the cavity. Hot moist gauze controlled the rather rapid oozing of blood into the pocket from which the tumor had been removed. Before closing the bladder it was observed that a dense, fibrous ring surrounded the neck of the bladder and presented positive and marked obstruction to the outflow of the urine. This ring was strongly dilated with a uterine dilator until it presented no further obstruction. Evidently this had had a marked bearing on the development of the diverticulum. The wound in the bladder wall was closed with several layers of chromatized catgut; reinforced until the closure seemed satisfactory.

At this point effort was made again to identify the left ureteral orifice which had been disturbed by the operative manipulations, but it could not be identified. However, no leakage of urine could be seen outside of the bladder on that side and the discharge of the urine into the bladder seemed regular. From this observation it appeared highly desirable to catheterize the ureter of the side involved previous to beginning the operation so that it might be identified at any step. This was carried out with complete satisfaction at another, subsequent operation. The anterior wound of access through the bladder wall was closed tightly with a continuous chain-stitch of catgut, without drainage. Two cigaret drains of large size were placed in the pocket to the left of the bladder and were brought out of a stab wound in the left inguinal region, serving the good purpose of providing ample drainage without interfering with the union of the abdominal wound. The muscles of the abdominal wound were united with catgut; skin with silkworm-gut without drainage. A retention catheter, size 20 French, was left in the urethra. Considerable drainage of bloody serum and urine escaped from the stab wound in the next two or three days, due largely to the fact that the catheter became slightly displaced, but on replacing it and applying the Bremerman suction drainage apparatus this impediment was relieved and the operative field remained dry thereafter. No bleeding nor any objectionable symptoms occurred. The only rise in temperature at any time was on the third day, when it was 100 F.; the remainder of the time it was normal. No drainage occurred from the wound after the fifth day; primary union occurred throughout. In a week the patient was able to urinate voluntarily, completely emptying the bladder.

December 15 (the sixth postoperative day), the wound was dry, all sutures were removed and urination was normal and not attended with residuum. No measures were necessary thereafter.

Case 2.—An American manufacturer, aged 39, at the time of his first visit, July 21, 1913, was referred by Dr. J. T. Barbee. The earliest memories of childhood of the patient were connected with slow, difficult, prolonged urination, frequently repeated. He was never able to urinate promptly and satisfactorily as compared with other children of his acquaintance. This difficulty persisted throughout his younger life, and about fifteen years ago there was an increase in the various symptoms, including painful urination, infection, intense clouding of the urine, constant desire, etc. There had been no bloody urine that the patient had noted except after using the catheter, which he had begun about a month previously and had used daily since. The white sediment in the urine he had noticed for the previous ten years. He had found a glassful of urine left over after each effort of voluntary urination. His general health had been poor; he has always been thin and anemic. There was never a definite investigation of his condition prior to March, 1913. At that time Dr. Barbee examined and recognized obstruction at the vesical neck and prescribed irrigations to relieve the infection, together with the use of sounds. This produced only partial success so that the patient was referred to us, July 21, 1913. Neither palpation by rectum nor cystoscopy disclosed any evidence of prostatic enlargement or outgrowth. On the contrary, the prostate seemed unduly small. There was, however, a large, relaxed, atonic bladder holding from 25 to 35 ounces of urine without difficulty; and through the cystoscope was observed at this time the opening of a diverticulum located in the posterior wall of the bladder, low down. Although no especial resistance to the dilator was encountered on the introduction of this instrument, the above evidence, together with the history, led to the conclusion that there was contracture at the vesical neck and a diverticulum connected with the bladder was noted. Both ureters were catheterized, and healthy urine was drawn from each.

At this time the operative technic for diverticula had not been worked out to the degree of satisfaction since attained, so that it was concluded to omit operative measures on it and apply those for the purpose of removing the obstruction at the neck. At this time the usual quantity of residual urine following voluntary urination was about 28 ounces. Progressively increasing dilation of the neck by means of the Kollmann dilator improved the patient's ability to urinate and reduced the quantity of residuum to about 8 ounces within a month. It did not relieve the infection or relieve him from the recurrence of septic urinary chills and fever that had been one of his most disagreeable symptoms. After a period of this form of treatments given at home the patient returned, Jan. 13, 1914, and was found again to have 20 ounces residuum. Then a perineal urethrotomy was made; a finger introduced through the perineal wound revealed a definite ring of fibrous tissue that surrounded the neck of the bladder and made positive resistance. This was at first stretched widely with the uterine dilator; but being still appreciable it was incised with the probe-pointed bistoury until free access was obtained. Drainage by means of a urethral catheter was secured.

Great improvement ensued, but still there was a tendency later to recurrence, which was treated with dilatings. The residuum was then reduced to 2 or 3 ounces, less than ever before. After the patient went home the dilatings were continued even up to 45 F., but the benefit was not maintained. Frequent chills and fever and other manifestations of urinary sepsis recurred, and the patient's health continued below par so that when he returned in January, 1917, we concluded it best to go at once to the removal of the diverticulum, which was then believed to be the cause of the continued disturbance.

Cystoscopy again confirmed the presence of the diverticulum, the orifice of which seemed to be even larger than it had been in former years. The operation was done, Jan. 20, 1917; ether was administered by Dr. Clapsaddle; Drs. Moore and Woolsey assisted. The same method as in the case previously reported was carried out. About ten yards of gauze in strips was packed into the diverticulum, the peritoneum was stripped from the bladder, diverticulum, the latter being very inconveniently located under the base of the bladder. This, however, did not prevent its enucleation, after which it was resected. The opening was sutured tightly with chromic catgut. Before closure of the anterior vesical wound, the fibrous tissue surrounding the neck of the bladder was again demonstrated with the finger, though it was not nearly so tight as formerly. It was widely stretched with the uterine dilator until it offered no further resistance. The bladder wound was then sewed; a stab wound to the left of the bladder was made for draining the cavity from which the diverticulum had been removed. The bladder wound and abdominal wound were closed without drainage.

Following the operation there was scarcely any bleeding; there was good drainage and no systemic reaction. January 25, the patient was in excellent condition. There had been only a small amount of drainage from the stab-wound. The cigaret drain was then removed. The retained catheter was removed from the urethra, January 31, and the patient's ability to urinate freely and to empty the bladder completely was then demonstrated. The patient could not remember ever having been able to urinate with such completeness and satisfaction. This practically completed convalescence, and he went home in good condition.

THE RESULTS OF TREATMENT OF BLADDER TUMORS *

JOHN T. GERAGHTY, M.D.
BALTIMORE

The treatment of bladder tumors prior to 1910 was in almost all cases a surgical one, with an attempt at partial or complete removal of the growth. Whether the tumor was benign or malignant, operative procedure offered the only hope of cure or alleviation. The brilliant results obtained by Nitze in his endovesical treatment of bladder tumors were not duplicated by other urologists, as the skill necessary for the employment of his methods was not perfected. The introduction of fulguration by Beer and later the employment of radium are two procedures which have served radically to change our ideas, and have consequently affected our attitude in the selection of the proper treatment for any individual case.

When fulguration was first employed, the results obtained by different surgeons were apparently immeasurably superior to the results secured by old operative methods. It began gradually to be realized, however, that all vesical tumors were not amenable to this form of treatment, and that while certain tumors disappeared with surprising rapidity, others responded only after long and vigorous applications, while others again were not affected in the slightest degree.

In order to secure an explanation of the difference in the response to treatment, we have made a study of the pathology of the different tumors and tried to correlate the different types and their response or resistance to fulguration. The results of this study have shown that the tumors which respond most readily to fulguration belong to the benign papilloma type, while those which are not affected, or are often stimulated in their growth, are histologically papillary carcinoma. There is, however, an intermediate group of tumors, the malignant papilloma, which varies in its response to this treatment, some responding almost as readily as the purely benign type, while others approach in their resistance the true papillary carcinoma. The differentiation between the malignant papilloma and the papillary carcinoma may, in many cases, be extremely difficult, and, notwithstanding the

histologic picture, the final diagnosis may be reached purely by the response to fulguration or radium. The employment of radium within the last few years has necessitated still further studies regarding the type of tumor in which this agent has proved valuable. As with fulguration, it has been learned by experience that certain tumors disappear under its influence, while others apparently are not affected by it.

Much confusion has always existed concerning the nature and pathology of bladder tumors. Most of this confusion exists as regards the papillary tumors which are the commonest of vesical neoplasms. Until a definite classification is adopted and a specific nomenclature employed, these inaccuracies will continue. For example, the use of the term "cancer" for the papillomatous, noninfiltrating types of tumor, even though there be histologically malignant changes present in the epithelium, is confusing, because experience has shown definitely that certain therapeutic measures suitable for one are wholly inadequate for the other. Frequently the surgeon in reporting the results of a given form of treatment for cancer may include in his series cases of malignant papilloma. The result of such a report leads to erroneous conclusions. A classification which has proved at least a satisfactory working basis is the following, because it is possible to correlate the histologic and clinical picture with the response to different therapeutic agents.

The papillary tumors may be classified as benign papilloma, malignant papilloma and papillary carcinoma. Papilloma is a name which common usage has popularized in medical literature, and it is used to denote a group of tumors having certain gross characteristics. The term "papilloma" has come to imply a pedunculated, papillary form of villous tumor springing from the mucous membrane of the bladder and being essentially composed of a branching connective tissue framework, lined by epithelium in several or many layers. Statistics prove conclusively that papilloma is by far the most frequent tumor of the bladder, and when it is further considered that practically all the papillary carcinomas represent an advanced malignant degeneration of tumors which in their early stages were papillomas, the preponderance of this type of vesical neoplasm can be appreciated.

The gross appearance of papillomas varies considerably, and there is no definite characteristic which will differentiate the benign from the malignant. In most instances it is impossible from the gross appearance to decide the character of the growth, so closely in general appearance do the benign and malignant papillomas resemble each other. The pedicle in the malignant papilloma is freely movable over the underlying mucosa, and there may be nothing in its appearance to reveal its malignant character. In the vast majority of cases, the differentiation between the benign and malignant papillomas can be made only by the most careful microscopic study, and it sometimes necessitates the examination of sections from various portions of the tumor. In the benign papilloma, the connective tissue axis is lined by an epithelium which has a palisade arrangement at the base and above this many layers of oval longtailed cells which are uniform in size, shape and staining characteristics. Toward the surface the cells become flattened, and the most superficial are similar to the epithelium of the normal bladder mucosa. In the malignant, the arrangement of the epithelium is changed, and instead of being in regular, uniform layers, it is disordered. The individual cells are very irregular in size and shape, and take the stain with varying degrees of intensity. These variations from normal are even more evident in the nuclei. At times, owing to the lawless growth of the epithelium, the papillae fuse so that the regular papillary arrangement is destroyed. Not infrequently in the same field, papillae may be seen undergoing various degrees of alteration. In one portion the epithelium may have all the characteristics of the benign papilloma, but close by may be papillae in which epithelial changes characteristic of malignant papilloma are very evident.

The term "malignant papilloma" should be reserved for those tumors in which the malignant changes are confined to the epithelium, and in which there is no infiltration of the epithelium into the connective tissue framework. When the epithelium breaks through its basement membrane and begins to invade the axis of the papilla or its main stalk, it no longer should be considered a papilloma, but a papillary carcinoma.

In order to arrive at some conclusion as to what may be expected from the different forms of treatment, we have included in our studies only those cases which have been seen since January, 1911. This makes it possible to compare our results of the last six years in which recent procedures have been employed with the results obtained prior to this time when operative measures alone were used. From Jan. 1, 1911, at which time fulguration began to be employed for the first time in our clinic, until April 1, 1917, 145 cases of bladder tumor have been observed. Of these there were 64 cases of papilloma, 74 of papillary carcinoma, 3 of adenocarcinoma, 1 of colloid carcinoma, 1 of cystic adenoma and 2 of multiple vesical polyps.

THE TREATMENT OF PAPILLOMAS

Of the sixty-five cases of papilloma in our series, thirty-four were treated by fulguration alone, the Oudin or unipolar current being almost exclusively used. In five of these, previous suprapubic excision had been performed and the tumors represented recurrences. In twenty-six of the thirty-four cases treated by fulguration, subsequent cystoscopic examinations were carried out, and in ten cases, or 29 per cent., recurrences were noted. In seven cases the recurrence was present in less than one year, in one case after one year, in one case after one and one-half years and in one case after two years. In three of these cases the recurrence was in the region of the original tumor, and in the remaining seven they were on portions of the bladder wall distant from the site of the primary tumor. Of the sixteen cases in which there was no recurrence, one patient was well for six years, one for five years, one for four years, three patients for three years, three for two years, two for one year and five for less than one year.

The recurrent tumors, with one exception, have all responded to fulguration like the original tumor. This one exception is of extreme interest.

CASE 1.—This patient had a papilloma several centimeters in diameter just back of the ureteral orifice, which disappeared rapidly under fulguration. For several months after the disappearance of the tumor, the mucous membrane in the tumor-bearing area appeared perfectly healthy. Shortly after, cystoscopy revealed a peculiar reddening and slight bulging of the mucous membrane in this region without ulceration or definite tumor formation. At first this was thought to be a localized inflammatory area. The process, however, seemed to spread, and a piece removed by the cystoscopic rongeur revealed an infiltrating carcinoma with the mucosa covering it practically intact. This is undoubtedly a case in which cancer cells from the malignant papilloma had metastasized into the deep bladder wall and there continued to grow after the original tumor had completely disappeared. This case really should be considered as a metastasis rather than a recurrence.

One other case is deserving of special mention because the recurrences continued over so long a period.

Case 2.—This patient, aged 52, was seen in February, 1912, with a large papillomatous tumor covering the left lateral wall and with several smaller tumors around the vesical orifice. The small tumors readily disappeared, but the large tumor responded only after months of vigorous and intense fulguration. Within a few months after the last vestige of the original tumor had disappeared, several recurrences the size of a pinhead were seen in widely separated portions of the bladder. These responded readily to fulguration. Since then the patient has been examined with the cystoscope on an average of about once a month, and practically at every examination small papillomas are found. During the last five years, probably several hundred tumors have been removed in this way. At the present time, the tendency to recurrence is just as active as it was five years ago, but it has been possible by watchful and persistent care to destroy the recurrence as fast as they form.

Treatment by Radium and Fulguration.—During the past two years, for papillomatous tumors which have shown histologic changes characteristic of the malignant papilloma or which were unusually resistant to fulguration, radium has been employed in combination with fulguration. Depending on the size of the tumor, varying amounts of radium have been employed, ranging from 200 to 1,000 milligram hours. Of the eighteen cases treated by this combination, in seven the tumors were multiple. Two patients discontinued treatment before the tumors had been removed. In the remaining sixteen cases, the tumors were completely destroyed. In all but one of these, subsequent cystoscopic examinations have been made, and in four cases, or 27 per cent., recurrences were found. In all four cases the recurrences were present in less than one year. The remaining eleven cases were free from recurrence for periods of time as follows: three for two years, four for one year, three for six months, and one for three months.

The following case illustrates the specific rôle which radium seems to play in rendering malignant papillomas, which have proved resistant to fulguration, amenable to this form of treatment.

Case 3.—A man, aged 75, had a papillomatous tumor 3 cm. in diameter just back of the trigon. Cystoscopically the tumor was pedunculated, with short stubby papillae. Microscopic examination of a piece of tissue removed showed the characteristic changes of malignant papilloma. The tumor was apparently in no way different, either cystoscopically or microscopically, from other tumors in which fulguration is effective. The tumor was fulgurated over a period of six months at biweekly intervals, and at the end of this time it was about three-fourths its original size. In the beginning of the treatment, the tumor decreased definitely but slowly, and finally it seemed to remain stationary in size. Frequently a fulguration sufficiently vigorous to coagulate apparently the entire tumor mass was employed, but examination two weeks later, on the separation of the slough, would reveal the tumor apparently unchanged. Finally radium was applied directly to the surface of the tumor, both the beta and gamma rays being employed. These radiations totaled 600 milligram-hours and were carried out over a period of eight weeks, 103 mg. of radium being applied for one hour at approximately weekly intervals. At the conclusion of this radiation, the tumor showed no evident changes either in size or appearance. The tumor was now vigorously fulgurated, and disappeared completely after one treatment. The patient died six months later of pneumonia. Necropsy revealed no recurrence in the bladder and there were no metastases present.

Up to the present time there have been six other cases responding only slightly to fulguration which, after varying amounts of radium, have yielded readily to the high-frequency treatment. All of these cases were of the malignant papilloma type.

Another case of considerable interest is the following:

Case 4.—A man, aged 50, had two papillomatous masses on the anterior bladder wall which had received a large amount of fulguration elsewhere without any apparent improvement. The resistance to this type of treatment was confirmed by us. A course of radium was then employed which was followed subsequently by fulguration, the tumors apparently disappearing promptly. Cystoscopy one month later revealed a recurrence in the same area. This was treated in a manner similar to the other tumors, with disappearance. There was noted on cystoscopy after the disappearance of the tumor, in the region formerly occupied by it, a small shallow cuplike depression in the bladder wall, resembling a cellule. Examination three months later revealed another recurrence. The tumor occupied so ideal a position for resection that operation was decided on. When the bladder was exposed, a diverticulum was found at the point of the insertion of the urachus. This was filled with tumor, which readily explained the recurrences. The diverticulum communicated with the bladder by a narrow orifice and the tumors previously destroyed were implantations of the tumor concealed in the diverticulum.

Treatment with Radium.—In three cases the papillomas were treated with radium alone, and in all three cases the tumors treated disappeared under the influence of radium. One of these cases is of particular interest in that the patient had numerous malignant papillomas around the vesical orifice and a localized infiltrating papillary carcinoma involving the right ureteral orifice. Any operative procedure, short of complete cystectomy and prostatectomy, would have been useless. It was possible, however, to destroy the papillomas by means of radium within a few weeks, after which a resection of the papillary carcinoma, with transplantation of the ureter, was successfully carried out. The papillary carcinoma and other forms of infiltrating malignant tumor, in our experience, as will be considered later, have not responded to this form of treatment, and resection was consequently indicated. This case probably illustrates very well the possibilities of a combination of treatments for securing results practically impossible of attainment by any one procedure.

Technic of Radium Applications.—In this connection it may be well to outline briefly the technic we have followed in the application of radium to bladder tumors. The treatment in practically all cases has been carried out with 103.7 mg. of radium element. In the majority of the treatments a fenestrated brass capsule has been employed and both the beta and gamma rays utilized. In other cases, however, the radium has been contained in a capsule of platinum 1.5 mm. in thickness, a screenage sufficient to filter out practically all of the irritating beta rays. The capsule containing the radium had been introduced into the bladder in the beak of an instrument not unlike the sheath of the irrigating cystoscope. These instruments permit the passage through them of an observation cystoscope by means of which the tumor may be viewed and the radium accurately placed on it. After the radium has been directed against the tumor, the instrument is held in a fixed position by means of a mechanical arm attached to the cystoscopic table. The radiations are usually given throughout the period of an hour at each seance and carried out from one to three times weekly, depending on the tumor and the reaction of the patient to the treatment.

Treatment by Suprapubic Removal.—This procedure was carried out in ten cases. In six of them the tumors were removed by the actual cautery and in four by resection. Of the former there were two recurrences in less than one year, while in the latter no recurrences were noted. It should be stated that in both cases in which recurrences were found the tumors were very extensive and occupied a large portion of the bladder wall. Of the patients treated by removal with the cautery, one has been well six years; one, two years; one, one year, and one for six months. Of those resected, three have been well five years, and one, one year.

PAPILLARY CARCINOMA

In eighteen of the seventy-four cases of papillary carcinoma, the tumors were considered operable, and in all of them radical resections were carried out. In five cases the ureter was transplanted, and in one case both ureters were similarly treated. In these eighteen cases there was only one operative mortality, that being the case in which both ureters were transplanted The death in this case occurred in the third week, being due apparently to pulmonary embolism. It has been possible to secure data concerning all of the eighteen patients. Eight have since died, and of the ten living, one has been well for six years, one for five years, one for four years, and seven for less than one year. It is noteworthy that recurrence in the suprapubic scar, which was a not infrequent sequela in our earlier operation, has not been observed in any of these cases. This is probably due to the greater care which has been exercised in preventing implantations during operation.

In fifty-six cases, or 75 per cent., the papillary carcinomas were so extensive that radical excision was considered impossible. In eleven of our extensive cases fulguration was employed, but aside from symptomatic relief, nothing was accomplished. In a few instances, it was possible to destroy enough of the tumor to give temporary relief from mechanical obstruction, while in certain of the cases, hemorrhage was relieved. In no instance was it possible completely to destroy the tumor.

Treatment by Radium and Fulguration.—In eleven cases a combination of radium and fulguration was used. The radium in every instance was applied directly against the tumor mass, and varying amounts, from a few hundred to several thousand milligram hours of radiation, were given. In the majority of cases both the beta and gamma rays were employed, but in the remaining the radium was heavily screened with sufficient platinum to filter out practically all of the beta rays. The combination of radium and fulguration of this type of case in no instance caused the complete disappearance of the tumor, or, in fact, any marked effect on it. In some cases, however, some symptomatic relief was obtained.

Treatment with Radium.—In thirteen cases with extensive infiltrating carcinoma, radium alone was employed. The results in this series differ in no respect from the cases treated by the combination of radium and fulguration. As in the latter series, a number of cases were relieved symptomatically, but in no case was there complete disappearance of the tumor.

Diagnosis.—The study of our results strongly emphasizes the necessity of early differentiation of the papilloma from the papillary carcinoma, because the endovesical methods at our command have proved to be futile in the treatment of the latter type. On the other hand, these endovesical methods for the treatment of papilloma yield results incomparably superior to any of the more radical procedures. The differentiation of the benign and malignant papilloma, so far as treatment is concerned, is not so essential, for in the majority of the latter variety, fulguration proves most satisfactory. In the small group which proved resistant, the combination of radium and fulguration will accomplish the desired result.

The differentiation between the papillary carcinoma and the malignant papilloma is not always easy, but in the majority of cases cystoscopy, palpation, histologic examination of a portion removed and a consideration of symptoms, either alone or, as is usually the case, in combination, will furnish information sufficient to make an accurate diagnosis.

Cystoscopy.—It is surprising how frequently from cystoscopy alone one is able to distinguish the papilloma from the true carcinoma. While the pedicle of the papilloma is rarely distinctly visible, often the tumor mass can be seen to sway as a whole in the fluid, which indicates its pedunculated character; and at other times it is possible to view slightly beneath the mushroom-like edge of the tumor. It is impossible from the cystoscopic appearance of papillomas to determine whether they are benign or malignant. When, however, the malignant changes are so advanced that infiltration of the bladder wall has occurred, there are certain cystoscopic appearances which nearly always enable one to arrive at a fairly accurate diagnosis. The presence of necrosis in the papillae is indicative of carcinoma, and is usually associated with invasion of the underlying bladder wall. In the earlier stages, when the tumor has just begun to invade the bladder wall, it may not be possible cystoscopically to determine this point; but when the process is at all advanced, the tumor loses its pedunculated character and becomes sessile in type. Frequently, around the margin of the tumor is seen edema, or bullae, which are usually indicative of a cancerous invasion of the bladder wall below. At other times little tumor nodules can be seen beyond the main tumor growth. This again is indicative of cancer. While it is impossible definitely to describe all the appearances which serve to diagnosticate the papillary carcinoma from the malignant papilloma, the cystoscopist of experience is usually able to differentiate them, and it is interesting to note how frequently the cystoscopic diagnosis proves to be correct.

Palpation.—Occasionally, when the bladder is extensively involved with an infiltrating form of growth and the abdominal wall is thin and soft, the hard, irregular mass can be detected. When malignant growths occur on the posterior wall of the bladder, or on the posterior lateral wall, rectal examination frequently gives most valuable information regarding the nature of the growth and its extent, and frequently determines the possibility of complete eradication by operative procedures. When the growth infiltrates the bladder wall, induration can be detected, and the extent of the bladder wall involvement can be more or less accurately mapped out. About 50 per cent. of bladder tumors occur on the posterior bladder wall in a position accessible to the examining finger. Sometimes not only the induration is detected in the bladder wall, but later the seminal vesicles are also involved, and still later the prostate. In rare instances, the growth may extend through the rectum and a rectovesical fistula may result. This complication occurred in three cases in our series. It may be safely said that marked induration of the bladder wall, which is felt through the rectum, is strong evidence of carcinoma. In the female, valuable information regarding the condition of the posterior bladder wall may be obtained by vaginal examination.

EXCISION OF A PIECE OF TUMOR FOR DIAGNOSIS

For a number of years we systematically removed pieces of bladder tumor by means of the Young cystoscopic rongeur for the purpose of histologic examination. The information derived from this method would seem to furnish conclusive evidence of the nature of the tumor, and consequently enable one to select accurately the type of treatment best suited to the tumor in question. Unfortunately, the evidence derived is not always conclusive, because of the fact that the portion removed is not always a safe index of the character of the remainder of the tumor. The piece removed may show no, or very few, malignant changes, while other portions of the tumor may be definitely carcinomatous. When the piece of tumor excised shows, however, definite carcinoma, the employment of radical procedures suitable for the individual case should be adopted without delay, and time should not be lost in the employment of the usual endovesical methods of treatment. The excision of a piece of tissue will also prove of value in differentiating the different types of vesical tumors. It should be noted, however, that the removal of the tissue by this means has been criticized as increasing the risk of metastasis. This has not been our experience, and the information obtained frequently counterbalances the theoretically increased risk of metastasis.

SYMPTOMS

It has also been our experience that when a severe, intractable cystitis is associated with bladder tumor, the tumor has proved practically always to be cancer.

In rare instances, when the cancerous process is very early, it may be impossible to determine this by the usual methods. In these cases it has been our custom to test out, as it were, the nature of the tumor by means of fulguration and radium. If the tumor does not show prompt response to this combination, it can be assumed that it is of a cancerous nature.

METASTASIS

When the possibility of metastasis in a given case is considered, it is again important to know the type of vesical tumor concerned. In our series of sixty-four papillomas, 75 per cent. of which were malignant, four cases of metastasis were noted. In all four cases the tumor was a pedunculated papilloma, which in every instance disappeared completely under fulguration alone, or fulguration and radium combined. In one case, evidences of metastasis did not develop for four years after the removal of the primary tumor, but in the interval a great many recurrences had been destroyed.

Of eighteen papillary carcinomas in which the carcinoma was considered sufficiently well localized to attempt resection, and in which it was possible completely to remove the local growth, seven patients have since died of cancer and one of intercurrent disease. Of those living, only three have been well for a period of more than four years. When the carcinoma is extensive and deeply infiltrates the bladder wall, metastases are usually present. It should be recognized, however, that at times most extensive involvement of the bladder may be present with negative findings at necropsy, so far as metastases are concerned. In three of our cases in which the tumor was so extensive that complete removal seemed impossible, and in which death occurred while under observation, no metastases were demonstrated postmortem.

CONCLUSIONS

The results of our experience in the past six years may be thus summarized: It is essential to determine accurately the type of tumor in a given case, in order to select the treatment best suited to the particular type in question. The early recognition of papillary carcinoma is most essential, and the diagnosis being made, the tumor should be radically resected, if operable. In our experience fulguration and radium have proved valueless in the cure of this type of tumor.

In this connection, it should be emphasized that, following the complete removal of a papillary carcinoma by resection, a recurrence may develop which in some cases proves to be, in its early stages, a malignant papilloma, and in this stage will respond to fulguration, or to a combination of fulguration and radium. In three of our cases in which a papillary carcinoma was radically removed, recurrences were found later and destroyed, by fulguration in two cases, and by radium and fulguration in the third.

While the results following the use of radium in the infiltrating carcinomas have been disappointing, the response of the more resistant malignant papillomas to this agent has been most encouraging. Radium alone will unquestionably destroy both the malignant and the benign papillomas, and on account of its influence on the former makes possible their cure without the employment of radical procedures which would otherwise be necessary. It has been our custom, when the diagnosis of malignant papilloma had been made, to give a varying amount of radiation, dependent on the size of the tumor, and to follow this by fulguration. Some of our malignant papillomas, in which fulguration was first tried without success, radium has rendered readily responsive to this treatment. Indeed, several cases which have stubbornly resisted frequent and vigorous fulguration, after a course of radiation have responded promptly to this measure.

The development of the endovesical methods has rendered it possible to effect a cure in practically all cases of papillomas, and the employment of the more radical operative methods has not been productive of results at all comparable with those following the more conservative methods. With the exception of rare cases, in which an operative procedure is carried out, resection alone should be performed, because operation is indicated only when the tumor is a papillary carcinoma, and mere superficial destruction, as with the cautery, etc., will usually be futile.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LEWIS AND MOORE, AND GERAGHTY

Dr. Edward L. Keyes, Jr., New York: As regards carcinoma of the prostate, I confess I have been a little more enthusiastic about "cures" than I am now. Without being cured these patients may stay in very good health, but even those who get brilliant results from a single treatment, like the two men shown here, have to be treated again and again, to keep those results good. Of course, the condition of the prostate itself is no index of the patient's general health. I saw a patient recently who was treated with radium elsewhere and whose prostate feels almost normal, but who is dying of carcinoma in his lumbar glands. But one would expect to cure patients captured early enough for radium treatment at a time when the carcinoma has not extended beyond the prostate.

Dr. Geraghty has noted that fulguration after radium works better than fulguration before radium. It seems possible that those tumors would have disappeared if he had been able to keep his hands off them for a sufficient number of months after the radium. I have seen a case of what Dr. Geraghty would call malignant papilloma improve very much in the second three months after a dose of radium.

Dr. William F. Braasch, Rochester, Minn.: As Dr. Geraghty has pointed out, the treatment of tumors of the bladder unquestionably has been greatly improved in recent years. It is reasonable to assume that in the first attempts to remove tumors by these less formidable measures a certain number of unsuitable cases would be treated, with consequent failures. If we were to judge the comparative value of nonoperative methods from statistics of past years, the operative procedure would suffer very much by the comparison. This is illustrated in recent papers by Drs. Gardner and Young.

The improvement in surgical technic has been along several lines. First, the bladders are cleaned up. Many of the patients with bladder tumor have a coincident cystitis and pyelonephritis and should be treated prior to operation much the same as patients suffering with prostatic conditions. Second, the wound should be carefully protected at the time of operation to prevent infection. Third, resection with the cautery knife is better than with the ordinary knife, and, together with cauterization of the surrounding area, should preclude any infection of the wound area. Fourth, formerly the ureters were often transplanted into other portions of the bladder with poor success, and sometimes with the death of the patient. If the ureter is markedly diseased, as it frequently is, it may be simply ligated and dropped into the wound. In such cases the kidney is usually largely destroyed and the patient does not suffer much reaction.

With the last year or two I have frequently seen patients who had been fulgurated over long periods of time. One patient had had forty fulgurations in two years. When I cystoscoped him it was evident that he had carcinoma and that it was too late for resection. Undoubtedly the tumor could have been resected if the patient had been operated on earlier.

I wish to emphasize that if, after three or four fulgurations, and possibly after using radium, the tumor does not markedly decrease in size, there is no excuse for continuing such treatment, and surgical procedures should be used. We have tried radium alone in a few cases of carcinoma, but with poor results. I disagree with Dr. Geraghty when he says that if a tumor of the bladder cannot be resected there is no object in attacking it surgically. Unquestionably good results can be obtained by using a cautery and searing the tumor almost to the muscular wall.

Dr. G. G. Smith, Boston: I should like to bear witness to the efficiency of radium in one case which I have had under personal observation. About two years ago I operated on an elderly man and took out an adenomatous prostate and a papilloma of the bladder. He did very well for two years. About Christmas I cystoscoped him and found he had an infiltrating growth extending upward from the sphincter. I sent him to Dr. Barringer, who treated him with one application of radium. That was some six weeks or two months prior to this meeting. I cystoscoped him recently and the growth had entirely disappeared, as far as one could tell. There was some sloughing around the base of the bladder.

In regard to the treatment of diverticulum, there is one point in the technic. I am not sure whether it has been put on record or not. After a diverticulum has been freed outside of the bladder by dissecting around it, it is easier to cut off the diverticulum and to approximate the cut edge if the diverticulum is inverted so that it projects into the bladder. The cutting and suturing can then be done inside the bladder in a more accessible situation.

Dr. Leo Buerger, New York: The great value of histologic examination in determining the presence of malignancy is not sufficiently appreciated, because adequate material is rarely obtained by the cystoscopist. I have, therefore, made it a routine for a number of years to attack all papillomas situated in accessible portions of the bladder with the snare, through my operating cystoscope. With this procedure we can often succeed in removing papillomas *en masse,* sometimes in two or more pieces, and can often completely eradicate the growth in one, two or three sittings, following up the removal of the growth by fulguration of the pedicle. Thus, not only is the time of treatment, the number of séances of the fulguration method, much reduced, but the pathologist receives adequate material for the thorough investigation of the nature of the tumor.

I think it is bad teaching that permits the cystoscopist to determine by the effects of fulguration as to whether a given tumor is malignant or not. Many men are treating such tumors who are not sufficiently expert to know whether a tumor is responding or not, the lack of response being attributed to faulty technic, improperly applied or improperly functionating current, or what not. Thus, patients have been referred to me after having been subjected for weeks and months to the fulguration treatment, in which the application of the snare or operating forceps through the operating cystoscope permitted a diagnosis of carcinoma at the very first visit.

The snare is a simple instrument, and with a little practice can be applied almost as easily as a ureteral catheter.

Dr. Keyes: Do you fulgurate at the end of each treatment?

Dr. Buerger: Whenever feasible I fulgurate at the end of each treatment.

Dr. Martin Krotoszyner, San Francisco: With reference to the method used in the treatment of diverticulum of the bladder mentioned by Dr. Smith, I recall a patient 73 years old in whom a very large diverticular sac was drawn into the bladder, just like one would turn a glove finger; the sack was then resected and its cut edges were stitched by several rows of catgut sutures. The patient eventually made a good recovery.

While the early and radical operative removal of malignant bladder tumors must be always recommended and carried out wherever feasible, the observation, nevertheless, that not infrequently patients live longer without than with operative interference would open the question whether, in the absence of distressing symptoms, an operation is indicated in all cases and under all circumstances.

Dr. W. C. Quinby, Boston: I want to add my mite to the paper of Dr. Lewis on diverticulum of the bladder by the brief report of one case. A man aged 55 had suffered from intermittent chills and fever, which had kept him a chronic invalid for twenty years, until I eventually got hold of him and succeeded in demonstrating and removing a large diverticulum on the right side of his bladder, much in the same way as Dr. Lewis has detailed to us. The first point which I wish you to note is the long story of invalidism which these patients so often bring. I hope that that period is going to be much diminished in the future. It is now being much diminished; the more so as the attention of the general practitioner is more forcibly called to such lesions as a cause of pyuria. The second point of note occurred during the convalescence of this patient. While water was being given in very liberal amount to help out the severe renal infection, the heart suddenly became irregular and weak. It was impossible by the usual means to rule out an acute dilatation from too much fluid. The electrocardiogram, however, came to our assistance. The tracing showed the condition to be due to an auricular fibrillation and not to decompensation of the heart due to the fluid. I was able to continue the fluid, and, under appropriate treatment, the fibrillation ceased. The patient is now cured of his diverticulum.

Dr. Bransford Lewis, St. Louis: I think that Dr. Quinby and I have a similar impression as to the value of presenting these reports, and that is one of encouragement for undertaking, in the first place, the diagnosis of these cases, and, in the next place, operating. One of these patients whose case I reported had a longer history of trouble than the one that he speaks of. He was 42 years of age and gave a history that ever since he could remember he had had chills and fever and could never clean his bladder; he was always septic; and he recovered just as promptly as did the other. Before I undertook these operations I was rather fearful that they were difficult to carry out and that the convalescence would be prolonged. I remember in certain cases of other operators the patients did have very difficult convalescence. These men both were well within ten days after the operation, and were thoroughly comfortable, urinating and emptying the bladder completely, and happy over the result. I think encouragement is the keynote of the presentation of the cases.

Dr. John T. Geraghty, Baltimore: With regard to Dr. Keyes' remarks about the disappearance of these tumors under radium, I think that is perfectly true. In some of the cases which have been allowed to go without fulguration the tumors have disappeared. We have used fulguration to cause a more rapid disappearance of the tumor. Those which disappeared under fulguration after irradiation would probably have disappeared under irradiation alone.

With regard to the technic of resection, we make it a rule to burn the tumor vigorously before attempting resection. As soon as the bladder is opened the whole tumor is destroyed down to the base. Whether one carries on the dissection by the knife or the cautery makes little difference. When one destroys the whole area thoroughly it amounts to resecting that area of the bladder wall.

With regard to the cases mentioned by Dr. Braasch, it has been my experience that the tumors which we can destroy by the cautery are tumors that practically always respond to fulguration and radium. Those cases with infiltration I do not think would be cured by destroying with the cautery. There are a few cases in which the tumor is a definite, infiltrating carcinoma with a pedicle, and that tumor must be resected. Cutting off the tumor through the mucosa at the pedicle with the cautery is probably just as efficient as a resection.

With regard to the remark that the mortality from resection should not be as high as 12 per cent., our mortality in twenty-two resections has been one death.

A Family Epidemic of Syphilis.—E. Jeanselme reports that syphilis was brought into a previously healthy family by the soldier husband of one of the daughters. He had been at the front for nine months. Three weeks after his return to his troop from his brief furlough, his young wife and her nursing babe began to show syphilitic lesions. The child was weaned at the tenth month, and the grandmother and a younger sister, who tended the babe, both developed syphilids in the mouth and tonsils, and the latter in the skin. They also took care of the babe of a third sister, and this infant soon developed syphilids in the palate, with roseola and mucous patches in the mouth. The mother of this infant was infected in turn. There are now six syphilitic members of the family, and only three in the household are still apparently exempt. As one of these, a girl of 12, has been sleeping with the younger sister, she is probably infected likewise. In making his report to the Société médicale des hôpitaux (*Bulletins*, p. 854), Jeanselme added there is a regulation forbidding furloughs to soldiers in a contagious stage, and asked why this regulation was not enforced. The syphilitic lesions developed in the mouth of those tending the babes, probably from the habit of tasting the infant's food, using the same spoon.

A CASE OF CYSTITIS CAUSED BY BACILLUS COLI-HEMOLYTICUS

M. W. LYON, Jr., M.D.
WASHINGTON, D. C.

As little mention of the hemolytic properties of colon bacilli is made in the literature, the following report may not be without interest.

From a patient, an adult woman with some obscure bladder or kidney trouble, several samples of catheterized urine were collected in sterile bottles and submitted for bacteriologic examination with the suggestion that the case might be tuberculous. The urine when received was cloudy, but on standing or centrifuging rapidly settled out clear. Microscopically the sediment showed numerous pus cells, no casts, and large numbers of a doubtfully motile and gram-negative bacillus of general colon morphology. No acid-fast organisms were found in the urine.

Three guinea-pigs were inoculated in the groin with the centrifuged urine sediment as follows: Oct. 9, 1916, one was inoculated with the sediment of about 50 c.c. of urine, and died, November 6, showing at the site of inoculation a necrotic area and pocket under the skin, but no enlarged glands or other signs of tuberculosis. A mixed growth was obtained in cultures from the inoculation site and from the heart's blood. None of these organisms could with certainty be identified with those originally found in the urine. October 18, two guinea-pigs were inoculated with the sediment of about 100 c.c. of urine. One of these died, November 14, showing no evidences of tuberculosis, the chief lesions being ascites, slight peritoneal inflammation, and, as in the case of the first animal, a necrotic area and pocket at the site of inoculation. The third guinea-pig died nearly a week later, November 20, and showed lesions in every respect like those of the second animal. As in the case of the first guinea-pig, mixed cultures were obtained from the second and third animals, but none of the organisms so obtained could be identified with the original organism in the urine. It seems probable that the guinea-pigs died from slow toxic effects of the bacilli and pus cells injected, and that the inoculation sites became infected with outside organisms.

Four white mice were inoculated with the urine sediment, two intraperitoneally, and two subcutaneously at the root of the tail. All four mice lived about one month without showing evidences of ill effects of the inculations when, along with other mice in the laboratory, they were destroyed by rats.

Cultures of the sediment of the urine and of the urine itself were made with the following results: On plain agar, on starch agar, and on plain broth no growth was made. On coagulated pleuritic fluid, on hydrocele agar, and on Petroff's egg medium for tubercle bacilli, an abundant moist colorless growth occurred.

On blood agar plates by the addition of a few drops of blood taken from a finger to melted agar tubes and inoculated with some of the urine, colonies readily developed, in marked contrast to their absence when plated on plain agar. On the blood agar plates a distinct zone of hemolysis occurred around the colonies resembling that produced by *Streptococcus hemolyticus*. Four different samples of the urine were plated in the foregoing manner and always with the same results. After preliminary inoculations on the more special mediums, growth occurred on plain mediums.

After preliminary insolation the bacillus reacted on sugars as follows: Acid and gas with glucose, lactose, and mannite; no acid or gas with saccharose, raffinose, or inulin. Gelatin was not liquefied. Indol was produced.

A macroscopic agglutination test was made, with a suspension in salt solution of the bacilli grown on coagulated serum, serum from the patient, and serum from an apparently normal person. After five hours in the incubator the following unsatisfactory results were obtained, the marks in parentheses being those obtained with the normal serum: Dilution 1:10, — (++++); 1:20, ++ (++++); 1:40, ++ (+++); 1:80, ++ (++); 1:160, ± (+).

The organism seems to be the same as that which Schottmüller and Much[1] called *Bacillus coli-hemolyticus.* Schmidt,[2] in a review of hemolytic intestinal bacteria, says *Bacillus coli-hemolyticus* cannot be considered as a well established variety, and thinks the hemolytic properties of the organism are rather accidental. He does not believe that power to cause hemolysis is any special indication of pathogenicity.

The inability of this bacillus to grow on plain agar when first planted from the urine is very interesting, as colon bacilli are usually easy of cultivation. It shows a high degree of specialization and adaptability on the part of the colon bacillus when what is ordinarily an intestinal saprophyte can become so restricted in its habits as to need human blood or other complex proteins for its nutrition. Administration of hexamethylenamin in this case had no effect in restraining the organisms. The patient was given general and local treatment and an autogenous vaccine, and made marked improvement.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

CAMIOFEN OINTMENT.—An ointment obtained by mixing iocamfen (a liquid obtained by the interaction of iodine 10 parts, phenol 20 parts and camphor 70 parts, containing about 7.25 per cent. free iodine) with an equal weight of a mixture composed of lard, wax and oil of theobroma, but containing nearly all of its iodine in the combined form.

Actions and Uses.—The ointment has the properties of fatty iodine compounds, phenol and camphor.

It is used in various skin diseases, inflammatory swellings, itching, etc.

Dosage.—It is applied directly or on gauze, undiluted or mixed with fatty substances. The parts to which camiofen ointment is applied should be dry and the application of mercuric chloride before or after the use of the ointment must be guarded against.

Prepared by Schering and Glatz, New York. No U. S. patent or trademark.

Military Medicine and Surgery

PRESENT STATUS OF SURGERY AT CASUALTY CLEARING STATIONS

KELLOGG SPEED, M.D., CHICAGO
Fellow of the American College of Surgeons; Major M. R. C., U. S. Army
FRANCE

Service in two years of the great war, with an interval visit to civil life, leads one readily to comparative views. The periods of service have been passed at base hospitals and casualty clearing stations under British Expeditionary Force control. About one half of the base hospital work was performed under clearing station conditions, and it is desired to convey to readers in the United States a general conception of the progress of war surgery and of the detailed work of advanced casualty clearing stations.

ORIGINAL FUNCTION OF CASUALTY CLEARING STATIONS

The original function of casualty clearing stations was to act as a very advanced collective depot for patients from contributory field ambulances with their outlying dressing posts. The position selected was one within a few miles of the firing line, fairly well isolated and remote if possible from the danger of active shelling (chance shelling and aerial bombing must always be anticipated). The situation chosen must also be near the rail head, where ambulance railroad trains can be sidetracked and rapid evacuations practiced. The invaluable aid of gasoline motor ambulances makes these short transportations rapid and quite painless to injured men. Patients are brought from the field ambulances very quickly after their reception there, because little major operative work is attempted at these posts—merely a classification and dressing are all that is desired. Formerly the clearing stations did not attempt much surgery, especially in rushed times, but some serious cases were dealt with and retained, for which a relatively small but very efficient medical staff was maintained. Stations two years ago averaged a capacity of 200 wounded; they now can care for a thousand.

PRESENT STATUS

Method of Group Arrangements.—In the present status of casualty clearing stations, we find them grouped in series of three, in close geographical proximity, provided with ample staff and with tent facilities to withstand a maximum strain. This close position permits the feeding of one ambulance train from all three, and allows of the following arrangement: Motor ambulances with patients are received by No. 1 in the series of three, until 200 patients are taken in, or until twenty-four hours have expired from the time the first patient came in. The next station in the series then receives in like manner 200 patients or for a period of twenty-four hours; following that the third station completes the round. Such an interrupted distribution gives each station an opportunity to operate on the patients that enter and to evacuate rapidly as many as possible. Rest for the staff is also provided. The capacity for the wounded is equivalent to a thousand men. This does not, however, indicate 1,000 beds, because many men are left lying on the stretchers without being put in bed and are passed along thus to the base.

---

[1] Schottmüller and Much: München. med. Wchnschr., 1908, 55, 435.

[2] Schmidt: Centralbl. f. Bakteriol., Orig., 1909, 50, 359-373.

Method of Reception and Distribution of Patients.—This is simple. Separate reception tents are provided for walking and lying patients with a medical officer in charge of each. Officers—even prisoner officers—are segregated. Walking patients are dressed, fed and evacuated, unless they demand surgical interference, in which event they are sent to the theater for minor operations, cared for, and then evacuated in chronological order of reception.

Lying patients are distributed, marked with colored tags, into resuscitation, preoperative (major and minor) and medical wards (for gassed or other medical conditions). Not yet diagnosed patients or instances of doubtful diagnosis are carried to an examination room and are carefully gone over by two medical officers. For the resuscitation ward those patients are intended who are moribund. There are facilities for administration of salt solution, external heat and stimulants. The men are not handled or removed from their stretchers, so that this ward need contain no beds. In the preoperation ward the same rule is followed: Patients are prepared on their stretchers; a preoperative dressing is applied and they await movement, in order, to the roentgen-ray or operating room. The various tents and structures are so arranged, moreover, that a continuity of traffic of these patients is possible, resulting in no confusion of passing stretcher bearers or recarrying over the same ground. Human energy and distress of the patient are minimized. Hospital tents are marked with colored flags corresponding to the colored tags, so that bearers make no errors.

Personnel.—A commanding administrative officer, a head of the surgical division, a quartermaster, a laboratory officer, a roentgen-ray operator and various medical officers needed in the different positions outlined compose the official list. There are, of course, the necessary number of enlisted men, clerks, sergeants, servants, etc. In addition there are assigned to each station surgical teams, composed of picked men of surgical ability, each supplied with his own anesthetist, operating nurse and orderly. These teams divide the major and minor surgical patients in rotation as fast as they are able to finish each operation. Team work is divided thus: Each team works for eight hours a day, except during rush times, when they are expected to perform sixteen hours of duty. Three teams are on duty from 9 a. m. to 5 p. m. in the major theater, using five or six operating tables; two teams work from 5 p. m. to 1 a. m., and one team from 1 to 9 a. m. under ordinary conditions. The work is continuous as long as the hospital is taking in. Teams cease to take on patients one-half hour before the expiration of their time, so that their table may be cleaned and prepared for the next group.

Operating Theater.—The major operating theater is centrally located; the minor theater is near the dressing tent. All are electrically lighted. The arrangement of the five or six tables in the major theater permits the anesthetist to move from patient to patient in advance of the operator, while dressings and splints are being applied or the operation is being finished. The operating nurse assists the surgeon; the orderly brings supplies, helps with the dressings, and cleans up the table. There is complete independence for each team.

An ample supply of dressings, gloves, instruments and splints is at hand, and the sterilizers for instruments are constantly boiling during work. After instances of gas infection or before serious operations—especially head and joint—a complete clean-up of the surgeon and nurse is expected; otherwise, for extremity wounds, gloves may be washed on the hands, and then dipped into sterilizing solutions.

Nitrous oxid gas, ethyl chlorid, chloroform and ether anethesias are used. The Shipway warm vapor chloroform-ether apparatus is much in vogue, and is very useful for nasal anesthesia in head operations.

Great rapidity and thoroughness of operative procedure is required. In times of stress, the minor operating theater can be expanded to permit the performance of major operations.

Dictation of the pathologic condition found, together with the details of the operation, is made by the surgeon to a clerk who enters this information on the field card and then copies it into an operative book, together with the patient's name, rank, distribution, etc. A serial hospital number is given to each patient as he enters the reception tent. As he leaves, this is removed from the field envelop by the evacuation officer, in order to provide a record of each man and to prevent any one getting lost. Varying with the severity of the injury sustained, patients are retained for a period of from a day or two to ten days. Many are sent to tents near the evacuation compound to await removal to the base by train as soon as they have recovered from the anesthesia. No beds are needed in these tents. Wounded prisoners are given the same treatment as the allied soldiers.

Character of the Surgery.—The character and practice of surgery in these stations is fairly uniform. Team surgery has but recently been introduced; statistics, however, from a push still in progress have shown that individual suffering and length of convalescence are lessened and mortality greatly lowered by this method. The policy of operating as early as possible in at least 90 per cent. of casualties—except moribund patients—has come to stay. In brief, this course may be outlined as an intent to do radical early excision of contused and tousled tissues, to remove foreign bodies, to irrigate and close opened joints, and to close most wounds snugly thereafter if possible. The use of bismuth iodoform pertrolatum paste, to which I recently called attention,[1] varies with different surgeons. It has distinct value; its limitations demand a broader discussion. For gas infections or suspected gas infections, muscle group excisions, very radical in character, are indicated. The Carrel-Dakin solution irrigation method usually follows, and field envelops are marked C. D. so that the treatment may be continued on the train during transfer to the base.

Distribution of selected types of wounds to different groups of casualty clearing stations is also now being practiced. One group cares for all the head injuries in its vicinity; another all the chest and abdomens and another, extremity surgery so far as this is possible. It is understood, of course, that the surgeon cares for all wounds received by the man, regardless of the type of his most severe injury.

Head injuries are treated by complete excision of contused scalp and pericranium, bone edges and buried fragments. Dural and cortical tissues are gently trimmed off, and foreign bodies extracted when possible. Careful closure of the wound is very important, capillary drains being used, the scalp being dissected from the pericranium, or a plastic repair performed.

---

[1] Speed, Kellogg: Prompt Removal of Foreign Bodies in Gunshot Wounds, The Journal A. M. A., Sept. 29, 1917, p. 1079.

In all brain injuries, bromids are given, and the patients kept at rest for some time.

Chest injuries are likewise exercised, even rib excisions being performed; and pneumothorax is closed off, foreign bodies being extracted if possible. Hemothorax is aspirated early, and cultures are made. If positive, early drainage is performed.

In the extremities, all contused and dirtied tissues are excised down to freshly bleeding and contracting muscle, regardless of extent. Joints are approached with the greatest caution because the synovial surface may not be invaded. A painstaking careful dissection of dirtied tissues is made, and if the joint is opened or a foreign body is within, it is taken out, irrigation with neutral solution of chlorinated soda, ether, or the injection of glycerin-formaldehyd solution is made and then the joint is *quickly closed off* by suturing its capsule together or into the bone. The external wound is sutured or not depending on circumstances, and splint immobilization follows. I wish to impress the value of this method on surgeons entering war service. I have in preparation an article dealing with gunshots of the knee which shows plainly the great advantage of this treatment over the "leave-it-alone" or continuous irrigation treatment. All patients from casualty clearing stations are evacuated to the base as soon as they can be safely and consistently moved.

No. 12 Casualty Clearing Station, B. E. F.

FIELD SANITARY ORDERS

C. C. McCULLOCH, M.D.
Colonel, Medical Corps, U. S. Army; Professor of Military Hygiene, Army Medical School
WASHINGTON, D. C.

The science and practice of military hygiene, not so many years ago, in the field at least and on a large scale, was in a somewhat unsatisfactory state. It is true that we had ideas on the subject—many of them good ones—but some very important things were not known even so recently as the Spanish-American War. For instance, our ideas were comparatively hazy as to the methods of transference of typhoid fever; we did not know that flies act as vectors, and we had but crude notions as to the effect of contact in spreading the disease. The average physician knew little about the microscopic diagnosis of malaria. Much of the typhoid fever in our army camps was erroneously called malaria—to the considerable detriment of the sanitary situation. Again, we did not appreciate the great importance of what we now call "carriers" in the propagation of infectious disease, and consequently our quarantine methods were quite imperfect.

Decided changes have, however, occurred. As the result of great improvements in laboratory and experimental methods, and the application of these to hygienic problems, we have now formed rather complete ideas as to how camp sanitation ought to be effected, at least with reference to the most important of the camp diseases. Our doctrine has been abundantly verified by the results of the practical experience of our army surgeons. Many of them, certainly those who have had considerable field experience in later years, nowadays know what to do along these lines. If we could carry out fully the scientific measures that we now know how to apply, camp diseases would no longer be serious matters. The new men will readily learn in the instruction camps, or, if they do not have the benefit of these, soon after seeing active service with the troops, all the important points, most of them quite simple, as to what can and should be done in field sanitation.

The real issue of importance nowadays in military sanitation is whether those things that we know how to do and that can readily be done will actually be put into practice. This, in turn, depends almost entirely on whether the sanitary officer can obtain the cooperation of the line officers and soldiers. Everything in the army comes back in the end to the question of rank and command. I think that, without doubt, the most satisfactory—indeed, the only sure way—is to induce the commanding officer to issue a general sanitary order in the beginning, signed by his authority, and explaining in a general way the sanitary duties of the command, and the methods prescribed for their accomplishment. This persuasion ought not, in these times, to be very difficult. Laymen are coming more and more to realize that something must be done in the way of sanitation. Having issued this order himself, the commander will continue to support it, especially after he sees the results, including much benefit to his own peace of mind, that accrue from the plan.

The real secret of success in military sanitation—the key to practical results along these lines—is the sanitary order. I think the idea important enough, at least, to be exploited for the benefit of the many civilian physicians now in army service. A minor benefit accruing from the order is the avoidance of differences among medical officers themselves as to the sanitary measures advised in their several organizations. These might all be good and yet conflict with each other when it comes to the question of administration.

We have always had some notion in the Army as to sanitary orders and their value; but the first time that the idea was worked out in detail in a camp of large dimensions, and used in a practical way, was at the divisional maneuver camp at San Antonio, Texas, in 1911. This was, indeed, the first camp on a large scale, of which we have record in our Army, in which the sanitary arrangements and results may be said to have been entirely satisfactory. There was no serious disease—very little of any kind—thus affording a most striking contrast with our Spanish War camps of a few years before. The occasion was, indeed, an epoch-making one for field sanitation. The main point is that the remarkable sanitary results attained there coincided with the fact stated above, namely, that this was the first occasion of the issue and use as a working basis of the divisional sanitary order. We had the antityphoid vaccination, it is true; we had many improved sanitary methods; but that these really proved effective was no doubt largely due to the order. It was issued by Major-Gen. W. H. Carter, under advice of Col. H. P. Birmingham, division surgeon, and Major P. F. Straub, sanitary inspector. The experience was repeated, and entirely adequate sanitary results were attained in the division camp at Galveston, Texas, a few years later. Major-General Carter was again in command. Col. W. B. Banister was division surgeon, and Major R. B. Miller, sanitary inspector.

The following model for a divisional sanitary order, which shows about what we should aim at, is based on the San Antonio order, and is constructed in accordance with the form recommended by Straub.[1]

---

[1] Straub, P. F.: Sanitation of the Maneuver Camp at San Antonio, Texas, Mil. Surgeon, 1911, 29, 607.

MODEL FOR DIVISIONAL SANITARY ORDER

Headquarters, Nth Infantry Division,
(Place)
General Orders, (Date)
No. ——

The following regulations for field sanitation are published for the guidance of all concerned:

1. Division Surgeon.—The division surgeon is charged, under the commanding general, with the general conduct and supervision of the Medical Department of the division, and will make timely recommendation concerning all matters pertaining to the sanitary welfare of the command.

2. Sanitary Inspector.—The division sanitary inspector is charged, under the division surgeon, with investigating and reporting on the sanitation of the command. He will report the results of his inspections to local commanders as well as to the division surgeon. Commanders of all grades are responsible for the sanitary condition of the localities occupied by their commands and for the enforcement of sanitary regulations within their organizations.

3. Regimental Surgeons.—The senior medical officer of each regiment or other organization will make at least one inspection daily of his command, and report orally any sanitary defects, with proper recommendations for the correction of the same, to his immediate commanding officer, who will immediately take the necessary steps for their correction, if within his authority. If beyond his facilities, or if considered impracticable, he will immediately report the facts, with full explanation, for action of higher authority.

4. Water Supply.—All drinking water supplies will be disinfected by the hypochlorite process in the field sterilizing water bag. To prevent subsequent contamination, containers must be kept scrupulously clean and protected from dust and other sources of infection.

5. Disposal of Waste.—Defilement of the ground in or about the camp is absolutely prohibited, and organization commanders will be held strictly responsible for the sanitary police of their respective camps. (*a*) *Human Excreta.*—Human excreta will be disposed of in pits provided with latrine boxes; urine by day in urine soakage pits, and at night by urinal cans placed in the company streets. Pits and cans will be burned out with crude oil and hay, and seats scrubbed with cresol solution, daily. It must be remembered that fly-proofing is the essential end aimed at in these waste disposal measures. (*b*) *Kitchen Wastes.*—Each company or other organization will construct and use exclusively rock pile incinerators for the disposal of all solid and liquid garbage. Garbage cans must be kept scrupulously clean. For the general waste of the camp areas not under the jurisdiction of subordinate commanders, rock pile crematories will be erected and used under the direction of the regimental sanitary squad. No bath or other waste water collections that might breed mosquitoes will be allowed. (*c*) *Picket Line Wastes.*—Picket lines will be gone over daily, and all manure and sweepings collected and hauled to the designated dumping ground, where they will be burned in incinerators. The picket lines will be burned over weekly with crude oil.

6. Food and Drink.—No articles of food or drink will be sold in camp, except in the authorized exchanges, and no purchases of such articles made by soldiers, outside of camp, except from properly licensed venders. Company kitchens and mess rooms will be securely screened, or such additional or alternative method instituted, acceptable to the division surgeon, as will prevent access of flies and dust to food or its containers.

7. Tent Hygiene.—Organization commanders are directed to assure themselves personally that suitable ventilation of tents and sunning of tent areas are practiced by their men; as also, adequate personal cleanliness. Mosquito bars and head nets and prophylactic quinin will be used when directed by competent medical authority.

8. Quarantine.—All regulations imposed by competent medical authority as to isolation in the case of infectious disease, or prophylactic measures in regard to the same, will be scrupulously observed by the command.

9. Sanitary Squads.—Sanitary squads will be organized by the division surgeon for each regiment, or other organization. One of the regimental medical officers will act as local sanitary police officer. He will be assisted by a Hospital Corps sergeant and the requisite number of Hospital Corps privates and civilian laborers. These squads will do whole-time work, and will supervise and assist in the purification of drinking water, the disposal of camp wastes, and in disinfection. A general sanitary squad, under a divisional sanitary police officer, will also be organized for sanitary work not pertaining to organizations, such as the handling of manure, general drainage, antimalarial work, the final police of vacated grounds, etc. Civilian sanitary laborers will be employed by the Quartermaster Corps and turned over to the Medical Department. The sanitary police officers will make requisition on the chief quartermaster for such transportation, labor or material as may be needed for sanitary work; when assigned to this service, they will not be diverted to other uses except by orders from these headquarters.

By Command of Major-General Blank:
A. B. C.,
Chief of Staff.

Official.
X. Y. Z.,
Adjutant-General.

COMMENT

The foregoing order, as stated, follows Straub's outline, which is the best for practical purposes. In Sections 4 and 5, certain suppositions are made for clearness' sake, as to the water supply and the methods employed for the disposal of excreta. Of course, in some camps, the water supply might be piped from a pure source, and disinfection would not be necessary; or, again, the incineration method might be used for the disposal of excreta. In such cases, the order could easily be modified to correspond with the local situation. In most other respects, the order, as written, would apply in any situation. The order can also, when necessary, be easily changed to apply to a brigade or regimental or even smaller camp. In any case, however, an order should issue.

Field orders should not go into too much detail as to methods; merely the authority and a general statement as to the kind of methods to be employed are wanted. The details are described from time to time in circulars published by the Surgeon-General's Office or the War Department. The order, in other words, is not intended as a sanitary text, but merely as a sanitary *authority*. Directness and conciseness are necessarily the chief desiderata in military orders.

The model suggested is perhaps a little too long, but by making it long I have been able to include by mention, or at least by inference, practically all the subjects to which the neophyte in field sanitation would be likely to have his attention at first directed. It is hoped that a careful perusal of the order will clear up what at first seems a rather difficult matter, and afford an easy and satisfactory means of orientation at this period for the new medical officer in the work of cultivating "preparedness" for his service in actual campaign.

The medical officer should never forget that *results* are what the nation demands. They must be produced. The way for the medical officer to secure them is to establish a satisfactory working relation with line officers, who alone have the power, and on whose action the successful or unsuccessful issue of the sanitary as well as of the military situation must in the final analysis really depend.

Army Medical Museum, Seventh and B Streets S.W.

THE VENEREAL DISEASES

(Concluded from page 126)

NOTE.—This is the fifth and final instalment of the series on "The Venereal Diseases." As already announced, these articles are being reprinted in the form of a manual which will be ready in about two weeks, price 25 cents.

PROGRAM OF ATTACK ON VENEREAL DISEASES

AN OUTLINE OF ACTIVITIES AND COOPERATING AGENCIES PLANNED TO REDUCE THE PREVALENCE OF THE VENEREAL DISEASES

Methods of attack on venereal diseases divide themselves into four classes:

A. Social measures to diminish sexual temptations.
B. Education of soldiers and civilians in regard to venereal diseases.
C. Prophylactic measures against venereal diseases.
D. Medical care.

A. SOCIAL MEASURES TO DIMINISH SEXUAL TEMPTATIONS:

(1) The suppression of prostitution and the liquor traffic.
(2) Provision of proper social surroundings and recreation.

These activities which have to do with social matters largely fall outside the jurisdiction of the medical service of the Army, but this service can render these activities more efficient by stimulating and supporting them, and wherever practicable such support should be given.

(1) Suppression of prostitution and liquor traffic in zones.

Keep careful track of conditions as regards these two matters in surrounding districts, in cities or towns where soldiers go, and in travel gateways.

In camps and zones, we have the following agencies which may be utilized:

The constituted authorities, military and civil.
The Commission on Training Camp Activities, War Department.
Local and national volunteer agencies may be utilized to discover failures and abuses, and to help otherwise in the work under direction of the proper authorities.

Outside the zones, a large number of forces can be used. Among these:

State Councils of National Defense.
Civil police and health administrations.
Associations of commerce.
Women's clubs.
The press.
Social hygiene and vigilance societies, and other social and religious organizations of influence in civil communities.

(2) Provision of proper social surroundings and recreation.

In camps and zones, plan to:

Develop social activities and amusements.
Provide places where soldiers may go for comradeship, to meet friends, to "loaf."
Supply an attractive place, or places, for soldiers to meet their women callers in camps and near camps.
Establish, under police authority, women patrols in zones.
Enforce rules against women being received in soldiers' tents or being allowed the freedom of camps.
Encourage facilities for interesting the soldier in reading, lectures, music, congenial friendships, hobbies.

For this purpose, we have for use in camps or zones, or both:

The Commission on Training Camp Activities, supervising activities of the Young Men's Christian Association, Playground and Recreation Association, Knights of Columbus, Young Women's Christian Association through its hostess houses, the American Social Hygiene Association, and other national and local organizations invited to carry on special activities.

Similar provisions for social diversions and proper social surroundings should be provided outside the zones, and if possible, provision at least for their inspection by military inspectors should be provided.

For use outside the zones, we have practically all the above agencies which are organized to conduct similar work in communities accessible to soldiers but not within the military zones.

An effort should be made to stimulate local organizations in towns near camps and at railroad centers to furnish proper social diversions and amusements for soldiers, and to provide places where they may go when on leave.

Enlisted men's clubs for this purpose, charging a small fee, say 25 cents monthly membership, are greatly to be desired.

Organizations of men and mature women to furnish members to meet soldiers in a friendly way, and to give them information and directions are desirable in towns and at railroad centers and other points in large cities where soldiers come in numbers. Fraternal organizations should be enlisted in this work.

Pressure should be brought to bear on the civil authorities to suppress vicious amusement places, to clean up parks and other recreation places, and to furnish for such places morals police. For this purpose, the members of special law enforcement organizations could be used.

Inspection of social and moral conditions in the camps, in the zones, and in contiguous districts and of the work being done by the various agencies for social betterment should be made by federal authorities. Similar volunteer inspections by dependable vigilance and other civic associations should be encouraged.

B. EDUCATION OF SOLDIERS AND CIVILIANS:

(1) *For Soldiers: (a) Lectures; (b) Pamphlets; (c) Exhibits.*

(a) Lectures to soldiers should be given by medical and line officers and by competent volunteers furnished by outside agencies, under invitation and direction of the Medical Department. These, beside inculcating continence, should explain the risk and waste of venereal diseases and the program adopted to avoid them. Lecturers without authority should not be permitted.

(b) A pamphlet should be given the soldier as soon as possible after enlistment. This pamphlet should be very brief and should warn the soldier of the venereal dangers to which he may be exposed and give instructions, if he should be exposed, to report as promptly as possible to his regimental infirmary.

It would be very desirable if a pamphlet could be distributed at the place of meeting of Exemption Boards. Later somewhat fuller pamphlets should be distributed to soldiers through medical and line officers, or by accredited volunteer social hygiene societies.

(c) Exhibits, such as the Coney Island exhibit of the New York Society of Social Hygiene, the exhibit of the National Cash Register Company, the exhibits of the Oregon Social Hygiene Society, the Missouri Society and other exhibits and demonstration methods worked out by the American Social Hygiene Association should be adapted to the needs of military life and furnished to each cantonment.

(2) *For Civilians:*

In the attack on the venereal problem, it is highly desirable that such educational activities as those outlined above for soldiers should be stimulated for the civilian population.

The influence of the military authorities should be given to the national organizations for social hygiene and to the numerous sanely conducted local organizations of the same sort.

Encouragement should be given to the organizations which are undertaking to arouse the interest of the woman population of the country in matters of social hygiene and for instructing women in regard to venereal diseases.

Organizations dealing with these matters which attempt to reach women should be encouraged, especially in the vicinity of camps. An increasing number of influential organizations, such as the General Federation of Women's Clubs and Patriotic Women's League, are indorsing and supporting sound social hygiene programs, and supplementing the more specialized efforts of such organizations as the Young Women's Christian Association and the Women's Christian Temperance Union.

C. PROPHYLACTIC MEASURES

Instruction in Prophylaxis:

Soldiers should be informed of the fact that there are prophylactic measures that reduce the dangers of venereal infection. But this instruction should take particular care to inform them that there are limitations to such prophylactic measures and that they furnish only partial protection and in no sense give freedom from risk.

Regimental Infirmaries:

The provision of prophylaxis (early treatment) in regimental infirmaries, which should be open day and night, is imperative in any sane attack on venereal diseases. The prophylactic station should be utilized as a place for personal advice and education against future exposure, and should be conducted as an early treatment dispensary. Any spirit of levity or condoning sexual promiscuity should be discouraged, and obscene stories or objectionable conduct should be rigidly repressed. The men assigned as officers in charge of these stations should be mature and with the personality and force of character calculated to gain the confidence and respect of the men applying for treatment. The medical officer in command should be impressed with the strategic importance of the prophylactic station for education, appeal, and the securing of social facts of vital importance in the prevention of venereal diseases.

Infirmaries in Civil Centers:

In cities, where there are no adequate civil dispensaries to be used and through which soldiers in considerable numbers pass, either while on leave or in travel, there should be provided in accessible locations regimental infirmaries. In a few cities, where dispensary services are particularly well developed, regimental infirmaries may be replaced to advantage by accrediting these civil dispensaries for use. Information should be furnished to soldiers of the existence and location of such regimental infirmaries and available dispensaries.

Leaves of Absence: In the interest of health, long leaves of absence for soldiers should as far as possible be discouraged. Leaves of absence of more than twenty-four hours are particularly dangerous, and it would be desirable if leaves of absence should be timed from as early an hour in the day as possible.

In cases where soldiers have been exposed, particularly if for any reason exposure seems unusually dangerous, special observation of such exposed men should be made, and if practicable these observations should be repeated at intervals of a couple of days for two or three weeks.

All pressure possible should be made by military authorities against houses or women which experience shows are frequent sources of infection, and this should be extended as far as practical to prostitution generally. The more effective the repression of prostitution can be made the greater will be the reduction in venereal diseases.

All possible influences should be brought to bear to encourage civil authorities in the attack on prostitution in all its phases. A medical program for civil communities equivalent to the military program for prevention and treatment should be encouraged.

D. MEDICAL CARE

Hospital Organization:

There should be a special service in each cantonment hospital to care for skin and venereal diseases.

As far as possible, all such cases should be in charge of the venereal service, and where, for any special reasons, such cases must be under other services, the senior officer of the venereal services should be, if possible, consulted in regard to them.

In the venereal disease service, there should be at the head an experienced specialist in these diseases, and whenever possible another medical officer trained in venereal diseases should also be in the service. The other medical officers assigned to the service need not necessarily at the beginning be trained in venereal diseases.

In the event that mature specialists from the Medical Officers' Reserve Corps cannot be furnished for the head of the service in each one of the cantonment hospitals, it would be practicable to use two half-time men, serving on alternate days, to act as head of this service, these men to be obtained from adjacent large cities. Under such conditions, there should always be furnished a qualified junior officer.

Instruction in Venereal Disease for Medical Officers:

One of the important functions of these services will be to train a group of men in venereal diseases. The service will, if well conducted, rapidly develop the knowledge of these diseases among medical officers.

It should be distinctly understood that one of the duties of the trained specialists who go into this service will be that of teachers of venereal diseases to the less well trained medical officers, and regimental officers should be encouraged to avail themselves of the opportunity for instruction furnished by these services.

Emphasis should be placed on the necessity of high standards of technic in carrying out treatment.

Hospital Cases:

The cantonment hospital should have under its care all cases of venereal diseases which are in the acute, infectious stages: These include:

All cases of acute gonorrhea.

All cases of syphilis during the early infectious stage and which have chancres, mucous patches, or condylomata.

But it should be seen to that hospitalization of venereal disease does not become an abuse which is allowed to interfere unduly with military duty.

There should be no leaves of absence for infectious venereal cases, and cases which have passed the acute infectious stage but which might become dangerous through the pos[illegible] mucous patches or of chronic [illegible] should not be allowed leaves of absence from camp.

Standard Records:

The syphilitic register of the army should be carefully and fully kept and social facts of epidemiologic importance should be secured in every case if possible.

Standardized Treatment:

An effort should be made to standardize in a general way methods of treatment, and provision should be made for some special instructions in venereal diseases for all medical officers who have charge of troops. To this end, a manual of instructions should be issued to each of the medical officers in the army. This should especially emphasize the great importance of early diagnosis and treatment in venereal diseases and outline suitable methods of treatment.

There should be furnished cards of brief instruction to patients with gonorrhea or syphilis.

Laboratory Facilities:

Laboratory facilities are necessary:

(1) For demonstrating gonococci and other bacteria.

(2) For demonstrating spirochetes by dark field illumination.

(3) For urinalysis (which should be required once a week for every syphilitic patient under treatment). These laboratory facilities should be in the wards of the venereal service.

(4) For Wassermann tests. These to be in the general laboratory.

Inspections:

In order to keep up a high standard of effectiveness, there should be provision for inspection of these services by special inspectors in venereal diseases from the Surgeon-General's Office. These inspections should cover each of the four classes of attack specified.

INSTRUCTIONS FOR THOSE HAVING SYPHILIS (SYNONYM POX)

Syphilis is a deceptive disease. Usually it is a very mild disease in its early course, giving the person afflicted with it little or no distress. Because it is so mild its victim is likely to pay little attention to it and to fail to go to the trouble to have it thoroughly treated. But in spite of its mild beginning, syphilis is one of the very serious diseases because, if it is not properly treated, it may later attack vital parts of the body and cause the greatest damage. It may produce ugly deformities; destroy health and shorten life; produce blindness and at times cause insanity. These results do not occur so often that you should become panic-stricken because you have syphilis, but they are common enough to make it necessary for your safety that you make every effort to get rid of the disease. These accidents of syphilis almost never occur in the early course of the disease. When they happen, it is usually years after infection, in cases which have not been cured.

The earlier in its course syphilis is thoroughly treated, the better are the results; it is, therefore, of the utmost importance to your future health and happiness that you should have your disease promptly and skilfully treated. If you do this, there is little danger that you will have further trouble from it; and after a few years you can marry without danger to your wife or to your future children. Your medical officers will attend to treatment of your condition, but it rests on you to do your part. Unless you cooperate and live up to instructions, treatment cannot be carried out with the best results.

One of the difficult things about syphilis is that to cure it often requires a long time—two years or more. In two or three weeks after you begin treatment, you will not know from any symptom that you have syphilis, and you will, therefore, be tempted to neglect further treatment. This is the great mistake that many persons with syphilis make. To insure future safety, treatment must be continued long after all evidence of the disease has disappeared. For your own good, you must see to it that you do not neglect your treatment after the first few months.

Syphilis is a contagious disease, but spreads only by contact with the virus or poison. The parts of the body that most often carry the virus are the mouth and the genital organs (privates). In order not to spread the disease you must be careful in your associations with others. If you are careful, you are not dangerous to others.

Obey the Following Instructions:

If you have any sore on your genitals, no matter how small, or if you think you have syphilis, report to your medical officer. Do not under any conditions rely on the "blood medicines" that promise to eradicate syphilis, and do not be caught by advertising doctors—quacks—who try to get your money by promising to cure you quickly. Do not let druggists prescribe for you; they are not qualified to treat syphilis.

Do not hesitate to tell your doctor or dentist of your disease. Later in life if you get sick at any time, you should tell your doctors that you have had syphilis, since this fact may furnish a clue to the treatment on which your cure depends.

Live temperately and sensibly. Do not go to extreme in any direction in your habits of life.

Try to get a reasonable amount of sleep—eight hours is the amount needed by the average person. And as a safeguard to others, sleep alone.

You should not smoke or chew tobacco.

Absolutely do not use alcoholic liquors. All experience shows that drinking — even moderate drinking — is bad for syphilis.

Take good care of your teeth. Brush them two or three times a day. If they are not in good condition, have them attended to by a dentist. But when you go to him, tell him that you have syphilis.

Do not have sexual intercourse until you are told by your physician that you are no longer contagious. It will interfere with the cure of the disease, and it is criminal, for it is likely to give the disease to your wife.

You must not marry until you have the doctor's consent, which cannot be properly given until at least two years have passed after cure seems complete. If you do, you run the risk of infecting your wife and your children with syphilis.

Early in the course of syphilis, while it is contagious, the greatest danger of infecting other people is by the mouth. Because of this danger, do not kiss anybody. Particularly, do not endanger children by kissing them.

Do not allow anything that has come in contact with your lips or has been in your mouth to be left around so that anybody can use it before it has been cleaned. This applies to cups and glasses, knives, forks and spoons, pipes, cigars, tooth picks and all such things. It is better to use your own towels, brushes, comb, razor, soap, etc., though these are much less likely to contamination than objects that go in your mouth.

If you have any open sores—you will not have any after the first week or two, if you are treated—everything that comes in contact with them should be destroyed or disinfected.

To live up to these instructions will only require a little care until you get used to them; after that, it will be easy. If you do live up to them, there is a good prospect that syphilis will not do your health permanent harm nor cause injury to others; and you will have the satisfaction of knowing that, after your misfortune, you have acted the part of an honest man in your efforts to overcome it.

INSTRUCTIONS FOR THOSE HAVING GONORRHEA

Clap—a Dose—Chordee (Painful Erection)—Swollen Testicle—Gleet

Gonorrhea causes so much discomfort that, unlike syphilis, it is not apt to be overlooked or neglected in its early course; but the discomfort of gonorrhea disappears long before the disease is gone, and patients are therefore apt to discontinue treatment before they are well. In such cases, the disease persists indefinitely as a morning drop or as "gleet"; perhaps not even these symptoms may be present, and the patient may suffer no particular discomfort of any kind, and yet be exposed to serious accidents to health and be a source of danger to any woman with whom he has intercourse.

It is a serious mistake to regard gonorrhea lightly. Gonorrhea may occasionally be very mild in its symptoms, but if neglected painful early complications and, later, very serious ones are likely to occur. Common early complications of gonorrhea are chordee, inflammation of the prostate and bladder, and swollen testicle. Common later complications are gonorrheal rheumatism, gonorrheal disease of the heart, and stricture. These later complications are all serious troubles. In addition to the dangers to the patient, uncured gonorrhea—which may show as a gleet or a morning drop or not at all—is as contagious as an acute gonorrhea; so that for the protection of your wife you must get well. Gonorrhea is the commonest cause of sterility and serious diseases of the pelvic organs in women.

The time to cure gonorrhea easily is early in its course. The sooner proper treatment is begun, the sooner gonorrhea can be controlled and the less likely are complications. After gonorrhea has become chronic, its cure is extremely difficult. It is, therefore, very important that the disease should be properly treated early in its course and that the patient should cooperate with his physician in doing those things which facilitate the cure. Gonorrhea can be completely cured, but in its treatment the patient must do his part.

Obey the Following Instructions:

Persist in treatment until your doctor tells you you are cured.

Do not try to treat yourself.

Do not use a patent medicine or some "sure shot" that may stop the discharges, but will not cure you.

Do not let an advertising doctor—a quack—get your money, and do not let a drug clerk treat you.

If you have had gonorrhea and you suspect that it is not cured, report to your medical officer.

During the acute stages keep quiet, and take little exercise. As long as you have any discharge avoid violent exercise, especially dancing.

In order to avoid chordee, while the disease is acute, sleep on your side, urinate just before going to bed, and drink no water after supper.

Never "break" a chordee. To get rid of it wrap the penis in cold wet cloths or pour cold water on it.

Except at night, drink plenty of water—8 or 10 glasses a day.

Do not drink any alcoholic liquors; they always make the disease worse and delay its cure. Also avoid spicy drinks, such as ginger ale.

Do not eat irritating, highly seasoned, spicy foods, such as pepper, horse radish, mustard, pickles, salt and smoked meats or fish.

Always wash your hands after handling the penis, particularly in order to protect your eyes. Gonorrhea of the eyes is very dangerous; it will produce blindness if not at once treated, and the infection is easily carried to the eyes on the fingers.

Keep your penis clean. Do not plug up the opening with cotton or wear a dressing that prevents the escape of the pus from it. Wash the penis several times daily.

Burn old dressings, or put into a disinfecting solution.

Never use anybody's else syringe or let others use yours. While you are using a syringe keep it clean by washing it in very hot water, and, when you have finished with its use, destroy it.

Avoid sexual excitement. Stay away from women. Do not have intercourse. It will bring your disease back to its acute stage and it is almost sure to infect the woman. Sexual intercourse while you have gonorrhea is a criminal act.

You are likely to obey instructions while your gonorrhea is acute, because it causes so much pain. Persist in them after the pain is gone; by so doing you will prevent relapses, make your cure much easier and more certain, and expose no one else to the disease.

THE TREATMENT OF EPIDEMIC POLIOMYELITIS WITH SO-CALLED SPECIFIC HORSE SERUM

The recent reports by Rosenow[1] and by Nuzum and Willy[2] on the treatment of epidemic poliomyelitis with the serum of immunized horses, for which excellent results are claimed, are of considerable interest. The horses were immunized with the coccus recently found by several observers in the central nervous system in epidemic poliomyelitis, and consequently the question of the exact relation of this coccus to poliomyelitis is again raised.[3] In both reports, it is asserted that the serum used has protective and curative powers with respect to the experimental poliomyelitis of the monkey produced by means of poliomyelitis virus, that is, suspensions in physiologic sodium chlorid solution of fresh or glycerinated nervous tissue from human beings that have died with this disease, or from monkeys experimentally infected. While the coccus with which the horses were injected unquestionably occurs in poliomyelitis, and frequently may be present in the so-called virus, its exact relations to the disease have not been made fully clear because thus far it has not been possible to produce poliomyelitis in the monkey by injections of this coccus in undoubted pure culture. But in spite of the lack of this essential link in the chain of evidence necessary to establish that the coccus is the cause of the disease, it must be acknowledged that if the serum of horses immunized with the coccus protects against and even cures poliomyelitis in the monkey, an adequate experimental basis for a thorough trial of such serum in the treatment of the human disease certainly has been provided. It is clear, however, that the results of further experiments on the action of the serum in monkey poliomyelitis are required before the claims in favor of its protective and curative powers may be regarded as fully established. At this point it may be stated also that the assertion by Nuzum and Willy that a coccus quite like the one found in the central nervous system in poliomyelitis occurs regularly in the cerebrospinal fluid of poliomyelitis patients, not being in accord with the results obtained by other observers, cannot yet be accepted without confirmation from other sources.

Turning now to a brief consideration of the recorded results from the use of serum produced as indicated, we find that Rosenow treated fifty-four patients with nine deaths, but that six of the patients that died were moribund when the serum was injected, "and hence should not be included as treated cases." This would leave a death rate of 8 per cent. Sixteen of these patients were in the preparalytic stage, and all recovered. Of twenty-three patients in the same epidemic, nine died (35 per cent.). The effects of the serum in the individual case are often striking, at least apparently, because the symptoms soon subside, paralysis, for instance, being arrested and sometimes disappearing completely if in the early stages. As rapid improvement may occur spontaneously in poliomyelitis, as the diagnosis in the preparalytic stage must be difficult (sixteen of the patients treated with recovery are said to have been in this stage), and as it is impossible to form any opinion whether the treated and untreated patients that were the subject of this report are fairly comparable, it evidently is necessary, as Rosenow himself says, that many more patients be treated before conclusions can be drawn as to the exact value of the serum he used.

Nuzum and Willy have treated 159 patients, eighteen of whom died (11.3 per cent.). Of 100 untreated patients admitted during the same period of time to the same hospital, forty-five died (45 per cent.). We lack, however, a more detailed comparison as to the ages, severity of attack and general condition of the patients composing the treated and untreated groups. We have no information whatever in regard to the principles of selection followed in forming these two groups; consequently it is difficult to determine how much importance may be assigned to the apparently very favorable figures given in this report. These observers also emphasize the rapid general improvement commonly seen after the injection of the serum, there being in many cases a critical drop of temperature.

In conclusion, it may be said that the injection of horse serum, in the manner described with detail in these two reports, appears to be quite harmless in poliomyelitis; that the authors of the reports are deeply impressed with the apparent good effects of the serum; that their figures appear to show a great reduction in the death rate, but that the figures are probably not to be accepted without the reservation that they may seem more favorable than is actually warranted. Further observations will be awaited with much interest. We hope it may be found, and quickly, that a potent, specific antipoliomyelitis

3. The Bacteriology of Poliomyelitis, editorial, The Journal A. M. A., April 14, 1917, p. 1122.

serum, protective and curative, has been discovered. The suggestion may be ventured that even if it eventually should be found that serum produced as described in these reports has little or no specific effect on the essential cause of poliomyelitis, its use may be followed by favorable results due on the one hand to general nonspecific effects such as follow the intravenous injections of foreign proteins, and on the other hand to its action, specific in nature, on the coccus used in the immunization, which may be a secondary invader of no little importance in poliomyelitis.

THE QUALITY GRADES OF PROTEINS

It is beginning to be recognized by all students of nutrition that proteins from different sources may have unequal nutritional value. This is exhibited, for example, in the unlike efficiency of different proteins in sparing the body from a loss of tissue protein; it is likewise manifested by the striking differences in growth on diets alike in every respect except the character of the proteins they contain.

The reason for these biologic differences is now known to lie in the amino-acid content of the different proteins. Those albuminous compounds, which furnish the essential amino-acids in proportions approximating the ideal as determined by the body's synthetic needs, are most economical from the standpoint of nutrition. As a rule, though by no means in every instance, the proteins of meat, fish, eggs and milk exhibit a superior value as conservers of body protein when they are contrasted with the proteins of the widely consumed cereal grains. It is for this reason that Graham Lusk has proposed the grading of protein products offered for sale. He has advocated the sale of food by calories and not by pounds as the foremost step in true food reform; but in addition to this he suggests the indication of quality distinctions.[1] For instance, such proteins as will replace body protein part for part might be classified as Group A. Gelatin has practically no power to replace body protein and is therefore put by Lusk in Grade D. Wheat contains a mixture of proteins of Grades A and D in which those of Grade A predominate, so that wheat may be classified as having a protein value of Grade B; whereas corn, from analogous reasoning, may be said to have a protein value of Grade C. Lusk's plan is conceived by him to work out as follows: An ordinary dietary with a liberal allowance of protein contains 15 per cent. of its calories in that form. A can or package of food containing 15 per cent. of its calories in protein should have, Lusk proposes, a star placed with the letter determination of the grade of protein. For example, the label on a can of corn might read: "This can contains *x* calories, of which *y* per cent. are in protein of Grade C."

The initiation of a plan such as that here developed would do scarcely more for man than has been attempted for our domestic animals during the past few years. Concentrated cattle feeds are commonly sold in containers plainly stamped with the proximate analysis of their contents, so that the addition of calorific values and quality labels would mean merely the extension of an already accepted principle in the feed industries. Hart and Humphrey[2] of the Wisconsin Agricultural Experiment Station have, however, recently pointed out certain practical objections to so much of the food classification scheme as has been reviewed above in relation to the quality of proteins. A few years ago it would scarcely have been anticipated that different proteins might exhibit supplementary values toward each other. The researches of McCollum, Osborne and Mendel, in particular, have made clear how an "incomplete" protein may be supplemented by a small quantity of another protein so as to produce a more perfect combination than either portion alone could exhibit from the standpoint of nutritive efficiency. It is further doubtless possible to select a combination of two "incomplete" proteins so that the mixture will afford all of the amino-acids of an ideal diet. In such an instance two proteins of Lusk's inferior Group C might yield a very satisfactory ration.

This is essentially what Hart and Humphrey have experimentally demonstrated in actual feeding experiments on a large scale on cattle. Thus they found that with corn stover and corn meal as the basal ration there were very appreciable differences in the efficiency with which certain protein concentrates could supplement such a ration for milk production. Gluten feed, for example, was measurably inferior to casein or milk powder.[3] In the proportions used and with corn stover as the roughage, none of several concentrates tested was able to maintain the animals in nitrogen equilibrium. Gluten feed was particularly unfit. But when the roughage was changed from corn stover to clover hay, the corn kernel being maintained as the basal grain, the inefficiency of the gluten feed as a supplement disappeared.[2] Evidently, Hart and Humphrey write, the proteins of clover hay will supplement the proteins of gluten feed in a much more efficient manner than will those of corn stover. These results, they continue, emphasize in a striking way the limitations of any classification of natural food in respect to the efficiency of their proteins, based on the determination of such nutritive value in a single food material or single mixture. When they are used in mixtures, as they generally are, the efficiency may be very greatly modified by the supplementary materials. This applies to human as well as animal nutrition.

Before condemning any particular type of protein or protein-rich food, it will be well to bear in mind that our dietaries usually are, or at any rate ought to be, drawn from varied sources unless we are certain of the adequate nutrient efficiency of the proteins supplied. The proposed classification of the proteins of foods into the Groups A, B and C, according to their physiologic value, has significance, as Hart and Humphrey insist, only so far as the individual food materials form the sole article of diet. In a mixture, Class A would probably always improve Class C; but it is possible to conceive of Class C proteins from independent sources making an efficient mixture. What applies to proteins is applicable in a somewhat comparable manner to other deficiencies in single sources of food. A suitable source of protein may lack desired inorganic elements or needed vitamins. Adequate nutrition is coming to be recognized more and more as a scheme dependent on the rational selection of suitable combinations of foods whereby their supplementary relationships can be duly exhibited.

THE IMPORTANCE OF FURTHER STUDY OF THE DIPHTHERIA GROUP OF BACTERIA

After the discovery by Loeffler and Hoffmann of an organism now known as *B. hoffmannii* or the pseudodiphtheria bacillus, morphologically identical with the diphtheria bacillus but seldom pathogenic and a nonfermenter of glucose, it was soon found that there was a whole group of diphtheroid organisms with slight morphologic and cultural differences, and identical with neither the true diphtheria bacillus nor *B. hoffmannii*. The intensive study of this group has never attracted investigators as it deserved, probably because of the general opinion that diphtheroids possess slight pathogenic powers and generally are secondary invaders. This opinion may be due to the fact that these organisms are so widespread, occurring in the air, in milk, and apparently at some time or other in nearly every organ of the body, normal as well as diseased. But their possible relation to Hodgkin's disease as indicated by the discovery of a diphtheroid (*B. hodgkinii*) in the lymph glands of this disease (Bunting and Yates and others) has reawakened interest in the whole group. In a recent review of the entire literature on diphtheroid organisms, Mellon[1] has conclusively shown that at times they may be the cause of various acute inflammatory processes. In many cases they are the only organisms isolated from such processes, and injection of suspensions of the killed organisms often seem to exert a marked benefit on the course of the disease. He cites cases, due to diphtheroid infection, of "tonsillitis, chalazion, acute and chronic purulent otitis media, arthritis, caseous and ulcerative lymphadenitis in cattle, bronchopneumonia, interstitial pneumonia, ulcerative cystitis, and an epizootic of infective abortion in guinea-pigs." He finds, too, that the difficulties encountered in correlating the work of various observers, and the multiplication of names and types are due not so much to differences in the bacteria themselves as to lack of uniformity in the mediums used in growing them and of well controlled immunologic studies. In many cases, reactions have been recorded by growth on glucose broth only. By the use of ten fermentable substances and a careful titration of the amount of acid formed in a definite period of time, and by the extensive study of immunologic reactions, especially complement fixation, Mellon thinks it is possible to divide diphtheroids into seven groups, four of which contain the greater number of saprophytes and three the greater number of pathogenic organisms, though any of the subgroups may become pathogenic under favorable conditions. One strain he found particularly interesting because of its pleomorphic character; under certain conditions of growth it assumed the form of a diplococcus, and it was only with great difficulty that it was brought back to the bacillary form. This relationship to the streptococcus was carried out in the immunologic reactions also, the relationship to some strains of streptococci being closer than to some strains of the diphtheroids.

The need for the further investigation of this particular sort of phenomenon is suggested also by Heinemann[2] in his report of a strain of diphtheria bacillus, otherwise typical, which on growth in glucose veal broth assumed a coccus form identical in morphology with the coccus form of Mellon's pleomorphic diphtheroid. This organism, however, could be easily reconverted into bacillary form by growth on Loeffler's blood serum.

THE LUNG PHENOMENA IN ANAPHYLAXIS

The phenomena of anaphylaxis have begun to play a prominent part in various departments of medicine. The anaphylactic nature of so-called serum sickness is now generally recognized, as it occurs as a direct consequence of the injection of a foreign protein into a human being. The analogy between asthma and anaphylaxis has been clearly set forth by Meltzer,[3] among others, who points out that in both conditions the symptoms consist in a tonic stenosis of the small bronchioles of peripheral origin. The connection of hay-fever with anaphylaxis is one of great likelihood, and current investigation is being guided in the direction of such probability. Zinsser[4] has remarked that there are a number of other clinical conditions which are less obviously anaphylactic in nature, but in which we have many good reasons for attributing an important part of the etiology to a state of hypersusceptibility. Thus the peculiar so-called "idiosyncrasies" observed in many people who suffer from urticarial skin rashes, gastro-intestinal difficulties, and even severe systemic illness after certain varieties of food seem to depend on an acquired or possibly inherited hypersusceptibility to the particular proteins involved, which, at certain times of abnormal gastro-enteric conditions, can get into the circulation in small quantity. It is not impossible, furthermore, that such unfortunate cases as the severe forms of angioneurotic edema, which seem, at least in part, to be associated with gastro-intestinal disturbance, and which may be transmitted from mother to child, have their root in anaphylaxis. For this, however, we have only inference based on clinical observation.

[4] Zinsser, H.: Infection and Resistance, New York, 1914, p. 433.

For the more accurate experimental study of the manifestations of anaphylaxis we are still restricted to observations on sensitive animals. In order to unravel satisfactorily the problems of clinical medicine in which the possibility of anaphylaxis can be considered, it is highly essential to continue the intensive investigation of the more purely experimental aspects of the subject. In some species, notably the very sensitive guinea-pig, the respiratory symptoms are the most striking feature of the clinical picture of anaphylaxis. During the later stages little or no air enters the lungs, although the animal makes violent respiratory efforts. This is due to a tetanic contraction of the small bronchioles which practically occludes the air passages. The conspicuous noncollapsible expansion of the lungs after death is due to the imprisonment of the air in the alveoli by the contracted musculature of the small bronchioles.

In the Department of Bacteriology and Experimental Pathology of the Leland Stanford Jr. University, Manwaring and Crowe[5] have found, through the study of isolated anaphylactic lungs by perfusion methods, that there are three types of pulmonary anaphylactic reaction, namely: (1) bronchial anaphylaxis, or the spasmodic contraction of the bronchial musculature, unassociated with recognizable changes in the pulmonary blood vessels; (2) vascular anaphylaxis, or the spasmodic contraction of the pulmonary blood vessels, usually accompanied with edema. The vascular reaction is usually followed by a mild bronchial reaction; (3) pseudo-anaphylaxis, or the plugging of the pulmonary blood vessels with thrombi and agglutinated corpuscle masses. Despite the seemingly technical character of such results, it is through investigations of precisely this sort, defining the mechanism underlying some of the conspicuous symptoms of anaphylaxis, that the understanding essential to progress in rational clinical therapy is to be derived.

Current Comment

HELPS TO THE SCOFFER AT FOOD VALUES

It is often said that necessity is the mother of invention; but necessity is also a good teacher in many other ways. In times of plenty we may be oblivious to the needs of the moment, whereas we soon learn to count the cost when "every little helps." Only a short time ago the earnest student of nutrition and dietetics was perenially twitted with the humor of the man who smilingly insisted that he wanted food, not calories. But times have changed, and the jokes about book learning and scientific feeding are replaced by an earnest desire for education in the tenets of nutrition. As Professor Bevier[1] of the Department of Household Science at the University of Illinois has aptly expressed the situation, with the shortage of food and the demands for saving it, there has come even to the mind of "the people" their helplessness because of their ignorance of food values. The people are writing to Washington, to the agricultural colleges, to anybody and to everybody for help in saving food. In response to this demand a great variety of helps to the housewife are appearing. Mr. Hoover's instruction card and the government devices are variations of lessons in food values. Every one understands perfectly that four quarters may take the place of one dollar in buying food, but many people cannot tell how many eggs at 40 cents a dozen may be used to replace in food value round steak at 25 cents a pound, or how to substitute for a quart of milk. It is easy even now to see that the term "food value" is beginning to receive respectful attention, and that way lies the basis for wise buying of food. War tends to make kindred of men. We can forgive the erstwhile scoffer, and we urge him to satisfy his newly acquired curiosity as to food values by consulting a timely series of well edited bulletins on "How to Select Foods," which the United States Department of Agriculture has lately put at the disposal of the public without cost.[2]

THE DANGER TO MUNITION WORKERS FROM TRINITROTOLUENE

Trinitrotoluene, or T. N. T., as it is commonly called, has been increasingly used abroad as a substitute for picric acid as a filler for shells, and is now used in America for that purpose. It has a lower melting point than picric acid, and is more stable; it is an explosive of the strength of nitroglycerin, and is manufactured by nitration from pure toluene. That it is dangerous to the human system we know from reports of necropsies in cases of fatal poisoning among trinitrotoluene workers, published recently in England and America; from the recent studies of cases of illness among trinitrotoluene workers in England by Panton,[1] and from Alice Hamilton's[2] study of four or five plants in America in 1916 in which she found 703 cases of poisoning, with thirteen deaths. In the manufacture of trinitrotoluene itself there is little danger to the worker, the process being carried out in closed retorts. But in filling the shells with the molten material, the workers are exposed to the fumes; and in chipping off the solidified trinitrotoluene from the top of the shells and boring holes in them for the detonator, they are exposed to the yellow dust. Occasionally symptoms due to the irritant action on the mucous membranes are observed, such as epistaxis, smarting of the eyes, constriction of the throat, and dry cough with a yellow bitter sputum. The toxic symptoms, like nausea, vomiting, anorexia, jaundice, mental depression, blurred vision and transient peripheral neuritis, are probably due to the absorption of the fumes and dust through the respiratory and the digestive tracts and especially the skin. The action of the poison on the liver seems to be marked. At necropsy the liver shows the most striking changes, and of the thirty-four cases of illness among the workers Panton studied, twenty-eight were cases of toxic jaundice. The microscopic study of the liver shows fatty changes of the liver cells, and in some cases increased bile duct proliferation, with infiltration of small lymphocytes around the ducts. Further, Panton examined the blood of a hundred apparently healthy women in a trinitrotoluene factory, and found the serum of twenty to be bile tinged. He suggests that even in the absence of symptoms there may be slight damage to the liver in these cases. The blood and blood-forming organs also are probably affected, for eight of the thirty-four patients showed anemia. This anemia Panton regards as of the aplastic type, that is, an anemia in which the number of the red cells is reduced while their form remains unchanged. He thinks the anemia is due to a destruction of the red marrow; and though rare among trinitrotoluene workers, it seems to be always fatal. The evidence on this point is still fragmentary, and needs for confirmation a careful study of the blood in more cases of poisoning, and further animal experiments.

PRIMARY PHLEGMONOUS GASTRITIS

Within the last few years the subject of phlegmonous gastritis has been investigated from various points of view, and reports of cases of this disease are now not infrequent. It would seem that the former lack of familiarity with the condition was due not wholly to its rarity, but in part to failure of recognition. The number and completeness of recent reports serve not only to stimulate the general interest in the subject, but also to increase greatly our knowledge of its various phases. Thus it now seems clear that the disease unquestionably belongs among the numerous manifestations of streptococcal infection. Phlegmonous gastritis may be superimposed on a chronic ulcer or carcinomatous process in the stomach, and in such case it may become the immediate cause of death. Of great interest are the cases in which the infection follows or accompanies an acute streptococcal process elsewhere, and especially noteworthy are the comparatively few cases in which the process in the stomach is the only focus of infection as far as the examination discloses. It is the latter group of cases that is most baffling; here the mode of entrance of the streptococci is often a matter of conjecture. Emge[1] described a case of this kind, but makes no suggestion as to the route by which the infection may have taken place. According to Emge, the streptococcus is the sole infecting organism in 70 per cent. of the reported cases of primary phlegmonous gastritis, and in the remaining 30 per cent. it is associated with the staphylococcus, the colon bacillus or the pneumococcus. The chief associated and probably predisposing conditions are alcoholism, dietetic errors, and food and drug poisoning. Streptococcus gastritis occurs five times more frequently in the male than in the female sex, and so far half of the cases have been found in laborers. Rixford[2] reports four cases, three of which occurred during the epidemic of streptococcal sore throat in San Francisco last winter. In such cases there seems no difficulty in accounting for the source of infection. The symptoms are sudden, severe from the onset, with a burning sensation in the stomach which is not relieved by drinking fluids, persistent vomiting, fever, not high at first but gradually or rapidly rising to 102 F. and occasionally to 105 or 106, and early prostration. The disease runs a rapid course, from three to ten days, and is usually fatal. The stomach wall is much increased in thickness and feels boggy, the mucosa is pale and swollen, and the folds are absent or indistinct. The mucous membrane is generally intact, but may be perforated or even entirely necrotic if the process has continued for some time. The submucous coat is greatly increased in width, often to the extent of half an inch, and firm, while the serosa is generally unchanged, but may be covered with a film of fibrin. There is an infiltration of leukocytes in the mucosa, but ordinarily the glands appear normal. There is a huge exudate of fibrin and leukocytes, both mononuclear and polymorphonuclear, in the submucosa, which is the part chiefly affected. The muscularis may be swollen and infiltrated with round cells, although generally little changed. As indicated, streptococci are easily demonstrable in the exudate.

Mortality Rates Among Negro Babies.—In analyzing the infant death rate for 1915, it was ascertained that while the infant death rate for New York City was 98.2 per thousand births, the infant mortality of the colored race was 202, as against 96.2 for the whites, a difference of 110 per cent. The health department then started an educational campaign, instituting intensive work along the lines usually found effective in reducing the infant death rate, and has just made public the results. While the negro death rate among babies in 1915 was 202, in 1916 it was 193.3 per thousand children born, and for the first six months of 1917, the rate was still further reduced to 180 per thousand births.

Medical Mobilization and the War

THE FULL SACRIFICE

♣ ♣ *Our country is at war. Men are called according to their talents and training to enter the different branches of the service. Physicians occupy an important place, and this applies particularly to those of special training. No choice has been left to youth because its strength and enthusiasm are called by the state. Men of maturer age have the glory of choice. They choose to serve or to let others serve.* ♣ ♣ *For the moment the enemy is at a distance, and those without imagination see him always there. Because disaster is still without our gates we feel secure. Many, therefore, are putting off the day of service. Some hesitate and question: a few even bargain.* ♣ ♣ *To relinquish individual liberty causes not a few to hold back. Yet those who have made the decision and are now doing the duties assigned to them as well as they may, cherish as dearly as the heart can the liberty to be with wife and family, to continue to engage in private or public practice, to carry on their investigations, to teach in hospital or medical school, and to provide for their old age.* ♣ ♣ *The right to these blessings of peace belongs to no one man. Some there are, however, who by actions or words seem to claim a right to these blessings over their brothers.* ♣ ♣ *No work is too trivial in a cause so sacred. Some have thought otherwise. But whoever is above the work which naturally falls to him, and works, if at all, only with reservations, misses the finest inspiration that duty fully done can supply.* ♣ ♣ *He who consciously or unconsciously allows self to decide in this matter is not to be envied. The spirit of service, which, if allowed, would almost transfigure him, he has failed to grasp. Greater peace can no man have than he who has made the full sacrifice.*

Commissioning of Medical Reserve Officers

The chief of staff of the Army has given instructions to the Adjutant-General that no more commissions are to be issued in any branch of the military service until a complete check is made of the number of commissioned reserve officers on the rolls. It is expected that this will hold up all the appointments for at least three, and possible four, weeks. Hence physicians who have applied for commissions must not be disappointed if they do not hear regarding them for the period mentioned.

Number in Medical Reserve Corps

On October 12, there had been recommended for commissions in the Medical Officers Reserve Corps approximately 17,500 physicians. About 1,200 of these finally declined to carry out their declared intention to accept commissions, and a few over 200 officers have been discharged for one cause or another, most of them because of physical disqualifications. Slightly over 13,500 have accepted their commissions. This number does not include, of course, the officers of the regular medical corps and of the medical corps of the National Guard, over 2,000 in all.

During the week ending Oct. 13, 1917, there were recommended for commissions in the Medical Reserve Corps 402 physicians, the proportion being seven majors, eighty-nine captains and 306 lieutenants.

Competition Increases

Capt. S. T. Millard, M. R. C., U. S. Army, Topeka, Kan., writes that Topeka has a better record than Sioux City (The Journal, Oct. 6, 1917) so far as physicians volunteering for the Medical Reserve Corps is concerned. With a population of 50,000 and eighty physicians, twenty-four physicians have volunteered for service.

Conference of Examiners for Medical Reserve Corps

At a meeting of the examiners for the Medical Reserve Corps, held at Fort Benjamin Harrison on October 8, a national association was formed with the title of the National Association of the Presidents of the Boards for the Examination of Applicants for Appointment in the Medical Reserve Corps of the United States Army. The following officers were elected: president, Capt. George N. Kreider, Springfield, Ill.; vice president, Major Robert D. Maddox, Cincinnati; secretary, Major Fred W. Bailey, St. Louis. An adjourned meeting will be held at the Congress Hotel, Chicago, Monday, October 22, at 3 p. m.

Creating a Dental Corps in the Army

By concurrence of the House in Senate amendments to House Bill 4897 in the closing hours of Congress, October 6, a Dental Corps has been created in the Army, corresponding to the Medical Corps, the membership of which shall have the rank, pay, promotion and allowance of officers of and shall be of the corresponding grade of the Medical Corps. Chairman Dent of the House Military Committee explained that the House bill relating to members of the Dental Service of the Army corresponded to the section of the national defense law which waived the former requirement of the law of five years' previous service in the Army as lieutenant before a member could be promoted to the next higher rank, and so on for the higher grades. The Senate practically adopted the House bill with the material amendment that a Dental Corps be created in the Army. Heretofore, the highest rank a member of the dental service could attain was that of major, and it would require twenty-four years of service before he could obtain that rank. At present the highest officers in the Army dental service have the rank of captain.

AMERICAN ASSOCIATION OF MILITARY SURGEONS

(*Continued from page 1273*)

Meeting at Fort Benjamin Harrison

The second day of the convention was opened by the president, Surg.-Gen. Rupert Blue. The first speaker of the session, Col. T. H. Goodwin, British Medical Service, dealt with the subject of the "Personnel of the British Army." The current of the thought in his address was sportsmanship, as illustrated by a favorite phrase of Colonel Goodwin's—*esprit de corps*. This he illustrated by many personal experiences with his troops. An officer and three of the enlisted sanitary personnel were in "No Man's Land" (called by Colonel Goodwin "Our Land," now that the British Army is gaining with every "show"), assembling the wounded, when a gas alarm sounded. This detachment was assisting in a particularly bad case at this time, and the wounded officer had no mask. It happened that between the officer and his three assistants there were only two masks all together. After each had refused, even when ordered to don a mask, one was finally put on the wounded man. The result was that later the wounded man was brought in alive, but the officer and his three men were found dead. That is playing the game, even though it is bad from a military standpoint, when four good men are lost to save one wounded, who may be permanently out of the war. Colonel Goodwin labeled as malicious lies the stories that the British Army is killing the wounded in the conquered trenches. "Quite the contrary," he said; "we make particular efforts to get them back to the dressing stations behind our lines." He said, "It will be this *esprit de corps*, which is such a dominant characteristic of the English-speaking people, that will win in this war, and never again will these peoples be separated, so long as the world lasts."

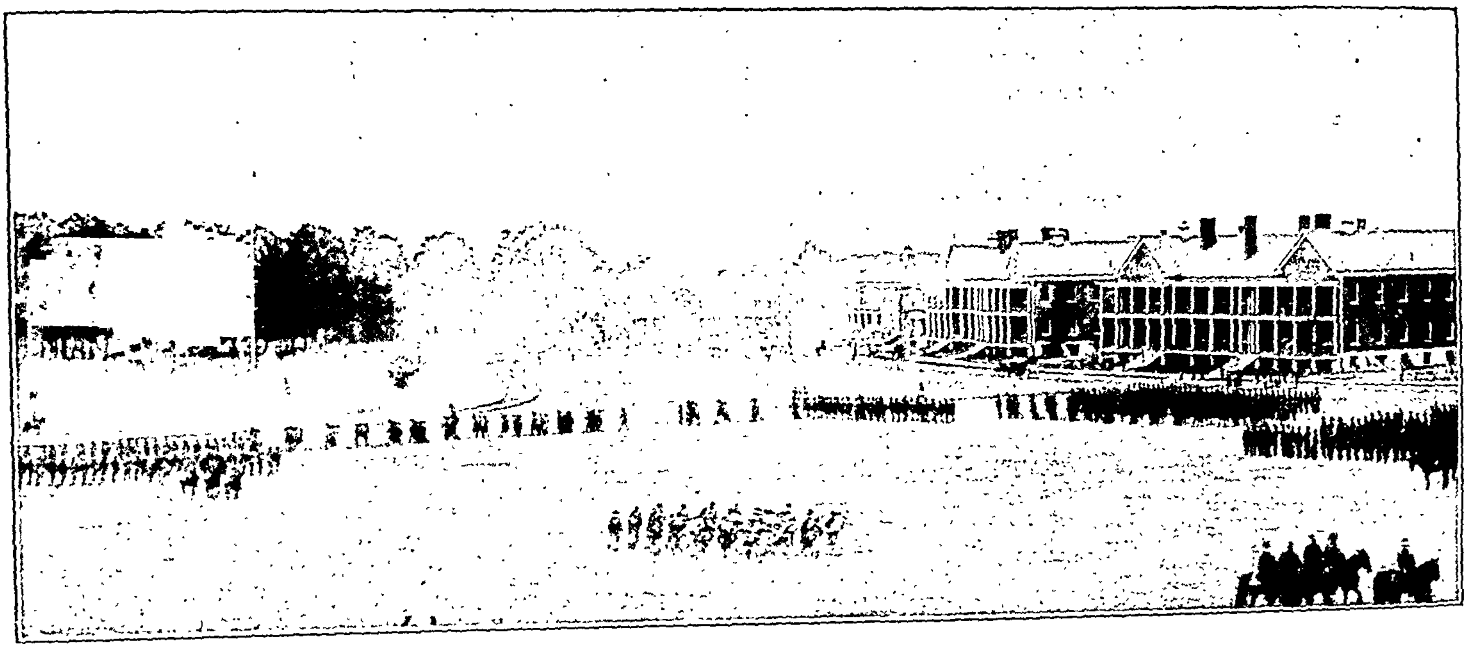
The next speaker, Capt. J. Gilmour, R. A. M. C., a veteran of many campaigns, though a young man, addressed the convention on the "Transportation of the Wounded on the Western Front." The address was extremely technical, but interesting to military men. The comparison of the British methods with those of our own Army shows that the United States has followed the British Army Sanitary Service Manual quite closely in writing its own. The scheme is illustrated by this outline: (1) Man transportation, by which the wounded man is carried on the bearer's back, or other scheme to get him back in the quickest and safest manner possible; (2) man transportation, with the use of litters and other apparatus not on wheels; (3) conveyances on wheels, drawn by men; (4) on animals' backs, mules, horses, etc.; (5) conveyances on wheels drawn by animals; these have been largely supplanted by motors; (6) railroad transportation; (7) water transportation. Captain Gilmour modestly remarked on the dryness of his topic, but followed the example of the other speakers, with a story of a personal experience.

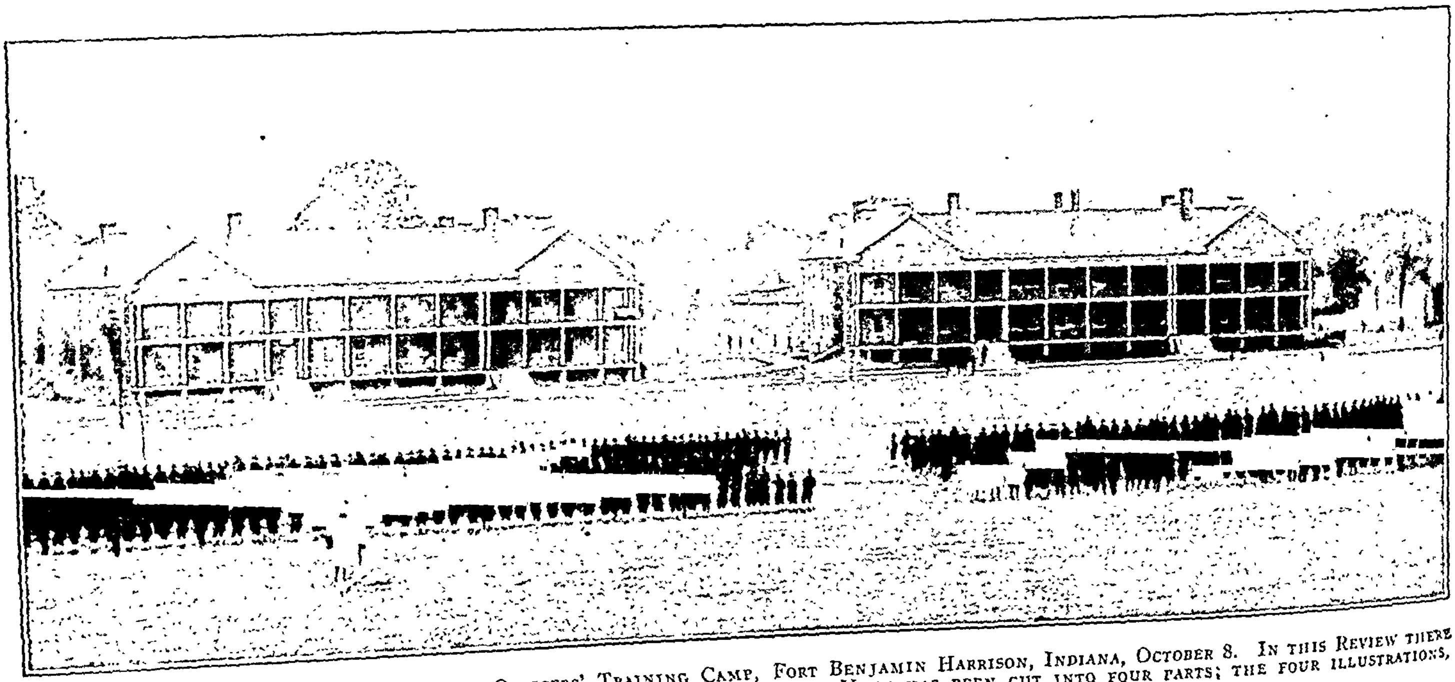
Prisoners were coming in after a particularly hard "show." Among them was a German officer. "I asked this officer, who was down on his luck and who spoke perfect English," said Captain Gilmour, "what he thought of the British charge. In reply, I learned that it was not much. He told me that our artillery fire was only fair. I finally asked him what he thought of the fact that the Americans had come in. He straightened up and said, 'That's bad. Now we have brains against us.'"

The "medics" of the Medical Officers' Training Camp took the point personally, and cheered wildly.

ADDRESS OF SURGEON BAINBRIDGE

Surg. William Seaman Bainbridge, U. S. Navy, spoke on "Reconstruction of the Crippled," and applied the subject to the reconstruction of the nations after the war. "I believe," said the speaker, "that the entrance into the war of my country means a better civilization for the future. I know that the people of Germany are heart and soul behind the kaiser in the war, and that the German women would drive the men back to the battle front if they showed any signs of weakening."





Parade and Review of the Medical Officers' Training Camp, Fort Benjamin Harrison, Indiana, October 8. In this Review there

Permanent Barracks. In order to permit reproduction this Panoramic View has been cut into four parts; the four illustrations,

FIELD MANEUVERS

The afternoon was devoted to practical demonstrations of field maneuvers by sanitary troops. These were explained by Lieut.-Col. M. A. W. Shockley, M. C., U. S. Army. The maneuvers were in the form of a terrain exercise, in which a position of opposing forces was assumed, and casualties estimated and placed on the terrain and tagged. Under these assumed conditions the surgeons of the various combatant organizations were required to issue orders and manage their organizations and establishments in accordance with the principles of sanitary tactics. The sanitary troops had established the necessary regimental aid stations, dressing stations, ambulance stations and field hospitals.

The convention, about 2,000, hiked to the trenches with the U. S. Army instructors and the distinguished guests from our

Allies. The dressing stations were established in ravines, in shelter, at the head of the sanitary line to the evacuation hospital. These stations consisted of tent shelters, to which the wounded were brought by the sanitary privates on litters, and in which they received first aid. From these stations the wounded were transported by mule ambulances to field hospitals, where they were given temporary treatment, consisting mainly of dressing adjustment. On account of the necessity of the mobile units accompanying the commands to which they were attached, the near approach of the enemy required that the wounded be evacuated to the base hospital as rapidly as possible. This movement was executed in a rapid manner; and the patients were transported to the railway hospital train brought from the base to a nearby station.

The visitors not only obtained a vivid picture of the work as done in actual battle, but also had the advantage of most interesting explanation by Lieutenant-Colonel Shockley.

ADDRESS BY COLONEL DIRCLE

In the evening, Col. Charles Dircle of the French Army exhibited moving pictures of the "Medical Service on the Western Front." It was an inspiration to hear him speak of France. His reverance for his country and his devotion to it were stimulating and worthy of emulation.

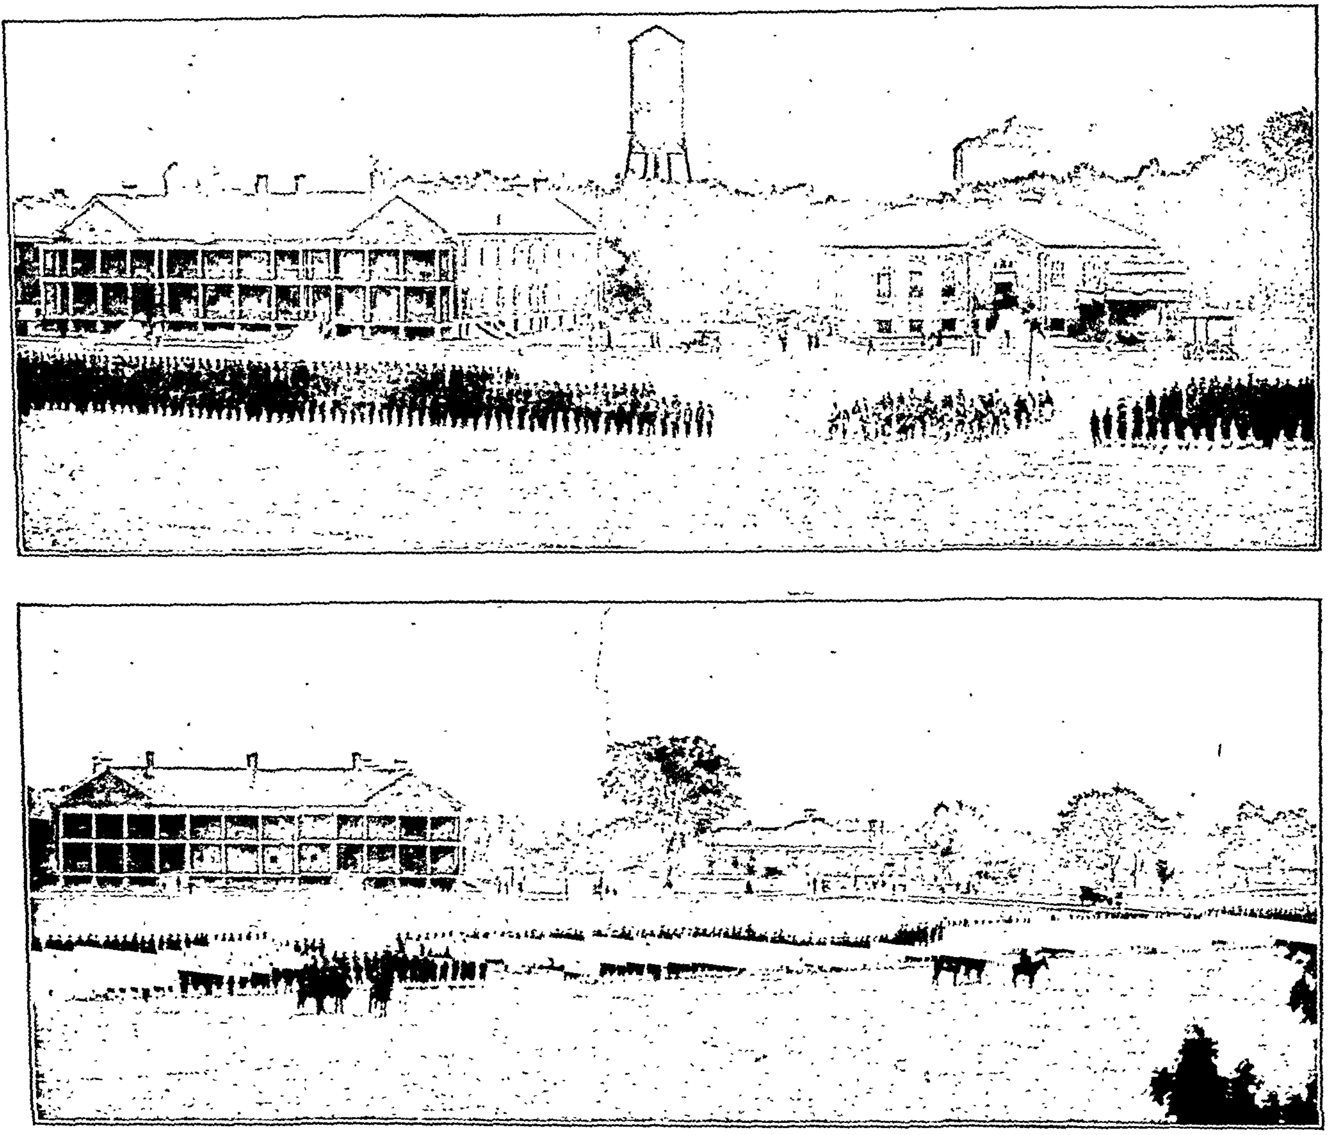
ADDRESS OF MAJOR SALMON

Major Thomas H. Salmon, M. R. C., U. S. Army, detailed to the Surgeon-General's Office, illustrated his address on "War Neuroses." "I think," said Dr. Salmon, "that shell shock is purely a neurosis and has no organic basis, but is founded on fear or horror. Early in the war these patients were treated in England by pampering and rest, with an insignificant number of recoveries. Since the establishment of the definite etiology, suggestion, persuasion and hypnosis have restored many to the battlefields." By elimination, wounded men and prisoners being used for the study of the condition, it was found that only twelve definite cases of shell shock had occurred among 60,000 prisoners. A correct deduction is simple.

The convention was closed on the third day by an interesting address by Col. T. H. Goodwin, British Medical Service, followed by the installation of the following officers: president, George A. Lung, Medical Director of the Navy; vice presidents, Lieut.-Col. Henry Allers, N. G., New Jersey; Brig.-Gen. Henry P. Birmingham, M. C., U. S. Army, and Asst. Surg.-Gen. J. S. Kerr, U. S. P. H. S.; secretary, Col. Edward Munson, M. C., U. S. Army (reelected), and treasurer, W. C. Rucker, U. S. P. H. S.

RESULTS OF THE MEETING

The holding of this meeting at one of the great officers' instruction camps has aided materially in impressing on the visitors the great need of thorough application for the attainment of technical knowledge of military affairs. The students in the medical camp also have profited immensely by personal contact with the guests, many of whom have been in actual campaigns within the war zone.



WERE ASSEMBLED OVER 1,200 MEDICAL OFFICERS AND ABOUT 2,000 ENLISTED MEN OF THE MEDICAL DEPARTMENT. IN THE BACKGROUND ARE THE
THEREFORE, MUST BE REGARDED AS A CONTINUOUS PICTURE, READING FROM LEFT TO RIGHT.

NEWS OF THE CANTONMENTS

[*From Our Special Correspondents*]

Thirty-First Division, Camp Wheeler, Macon, Ga.

The school of sanitation and medicomilitary tactics is progressing. Sessions are held four afternoons in each week; on Wednesday the officers of the mounted organizations take a ride into the country. These rides are a combination of pleasure, practice in riding, and instruction in topography and field work. Complete problems will be taken up soon.

NOTES

Major Harrold has secured medical officers to fill his compliment with the 121st Infantry.

Colonel Fisher of the Surgeon-General's Office inspected the camp, October 8. He appeared surprised to find a new motor ambulance company here.

Captain Pratt, M. R. C., is here to give instruction in gas defense.

The tuberculosis board is progressing rapidly; likewise the board on disease of the heart and that on mental diseases.

The base hospital will open about October 15, with some 250 patients.

The men of the ambulance companies are putting in an underground first-aid station close to the firing trench of the trench system now under construction. It will be fitted up as if for actual use, and used for instruction in gas defense.

As the division is now being filled up with draft men the sanitary units and detachments will also be filled. All units have already been organized, but there is a shortage of medical officers.

Capt. William A. Padgett of the Alabama National Guard has been promoted to major.

BASE HOSPITAL NOTES

The officers' quarters were completed, October 4, and promptly occupied. After several weeks in tents, the individual rooms were properly appreciated.

The administration building, receiving ward, two single ward buildings, laboratory building and operating pavilion are all practically complete, with the exception of electrical connections. The first is now being occupied by the administrative staff; intensive training and instruction is being given the enlisted personnel in order that they may be quite ready for their duties when we begin to receive patients, Wednesday next.

Lieutenant Horne, M. R. C., is now convalescent, following an operation for appendicitis.

Capt. Samuel C. Baker, M. R. C., specialist in brain surgery, reported for duty, October 10, and Capt. Francis R. Lyman, M. R. C., specialist in plastic surgery of the head, on October 11, thus probably completing the personnel of the staff.

ONE HUNDREDTH AND SIXTH SANITARY TRAIN

The camp hospital has still averaged 270 patients and great interest is taken by the local Red Cross in providing comforts. The meeting of the Red Cross, October 12, will surely be productive of added comforts.

Dr. Snavely of Atlantic, national director of the Red Cross, visited the camp hospital, October 12, and was greatly pleased with conditions.

The weekly social and dance took place Wednesday, and a most enjoyable time was had by all. Many visiting officers and ladies of Macon attended. Coffee and sandwiches à la buffet were served. Music was furnished by the Florida Field Hospital Orchestra.

The sanitary train is now being conducted as a regiment with its battalions of field hospital and ambulance companies. A supply organization is making its need felt.

The sick rate is dropping steadily.

Major George C. O'Connell, Alabama, has reported from leave of absence and is now on full duty.

Lieut. Edward S. Byrd of the (Georgia) Field Hospital No. 122, about to enter the ranks of the benedicts, is receiving the congratulations of brother officers. The lady is Miss Lucy B. Boyd of Enterprise, Ala.

Eightieth Division, Camp Lee, Petersburg, Va.

CONSTRUCTION OF BASE HOSPITAL

The past two weeks have witnessed rapid progress in the construction of the base hospital which although not completed, has received a large number of patients. The number, however, has been comparatively small, and has consisted largely of minor cases which could not be cared for in the regimental infirmaries. The staff has been working under difficulties owing to delay of manufacturers in sending equipment and a large part of the time of the staff has been occupied in making special examinations in doubtful cases shortly after the arrival of the drafted men.

The majority of the enlisted men are new and inexperienced in nursing, and the arrival of sixteen trained female nurses during the past week will insure better care for the patients. One woman arrived in camp alone, the first woman to stay here over night. What Major Hope christened her can readily be imagined. Congratulations are in order for Capts. J. Bayard Clark, M. R. C.; Ewing B. Day, M. R. C., and Samuel B. Moore, M. R. C., who now wear their well deserved gold oak leaves. There have been a few changes in the staff, as the following men have been transferred from duties in the division to assignments in the base hospital: Lieuts. A. C. Butcher, M. C. Campbell, A. J. Colborn, W. J. Davies and William F. Davison, all of the M. R. C.

The staff are comfortably quartered in the receiving ward and now have their own mess, and since Captain Merritt has had charge of it he is more popular than ever. Major Clark has been assigned to the work of supervising the care and prevention of venereal diseases in the division, and has devised a most satisfactory wash stand similar in shape to a urinal for the purpose of administering venereal prophylaxis. These stands are now being made and will shortly be installed. A prophylaxis station has been opened in Petersburg, and treatments are now given within a very short time after the men have exposed themselves to infection.

Col. Thomas Herbert Goodwin, C. M. G., D. S. O., of the British Army, assigned to the Surgeon-General's office of the United States Army.

PSYCHOLOGIC EXAMINATIONS

One of the most interesting and novel experiences which the medical officers have had at Camp Lee was the psychologic examination which was given by the ten psychologic examiners stationed here to examine the troops, under the direction of Lieut. Clarence S. Yoakum of the Sanitary Corps. Lieutenant Yoakum is professor of psychology in the University of Texas, and he and his assistants are well known in the field of practical applied psychology. The medical officers were examined at the request of Lieut.-Col. T. L. Rhoads, the division surgeon, with the hope that the examination would indicate in a general way the comparative adaptability of the different men.

The examinations were not difficult, but called for the alertness and accuracy so essential for a good soldier. No man can make a successful soldier or officer unless he grasps the actual meaning of his orders and knows how to obey them with precision and dispatch. The tests that were given rank the men on such qualities as these and, at the same time, rank them quite accurately on general intelligence. Tests have already been given to men of the regular Army and the results compare, in a high degree, with the estimates of the men made by the officers themselves. The gradings given compare quite accurately with the provisional estimate of the men made by Lieut.-Col. Rhoads and Major Schmitter. The results of the examinations of medical officers are very interesting. The base hospital physicians rank first, the regimental surgeons second and the Dental and Veterinary Corps, third and fourth. It is perhaps only fair to say that there were relatively few of the last two groups, so that their rankings are necessarily less accurate than the others. It required a staff of almost 100 men to give the tests and score and record the results. The tests created much comment and were enjoyed by the men as much as an interesting game would be.

EARLY DUTIES

The medical officers of the regiments have had their time very largely occupied in examining recruits, administering "triple typhoid" vaccine and learning their routine duties, and it has not as yet been possible to organize the sanitary personnel of the regiments and begin their formal instruction. This will begin shortly.

SANITARY TRAIN

The sanitary train under the direction of Capt. Elliott B. Edie, M. R. C., has been able to start systematic instructions. Lieut. Burr Ferguson, now Captain Ferguson, has been appointed instructor of ambulance companies by Colonel Hamilton, the commander of the trains, and work has been commenced. Drill, instructions and first aid will occupy most of the time during the first few weeks. The ambulance companies have been rechristened. Ambulance Company A, organized at Fort Oglethorpe, Ga., becoming No. 318; No. 43, organized by the Red Cross of Raleigh, N. C., is now No. 317, and Ambulance Company No. 46, organized by the Red Cross of Richmond, Va., is now No. 319. Odd numbered companies are motor drawn and even numbered companies animal drawn.

PAPER WORK

After the first quota of troops are examined this week the real work for the winter will begin, for which the regimental officers are all eager. Paper work is losing its terror and is gradually becoming comprehensive and easy.

HEADQUARTERS GOSSIP

The sanitary office, the headquarters of the division surgeon, is one of the busiest offices in the division, and Colonel Rhoads has already earned a reputation for industry and fairness. One of the assistants in the office, Capt. Hugh T. Nelson, Charlottesville, Va., quietly asked for a pass over Sunday and arrived back Monday morning but preceded by the announcement of his marriage to Miss Edith Rankin of Richmond, Va., on October 6. Captain Nelson is the only war bride among the medical officers since Camp Lee has opened.

Col. Percy M. Ashburn and Surg.-Gen. William C. Gorgas at the Medical Officers' Training Camp, Fort Benjamin Harrison, Indiana.

THE DIVISION OF INTERNAL MEDICINE OF THE SURGEON-GENERAL'S OFFICE

The following is a list of physicians—internists—who have been appointed chiefs of the medical service in the great hospitals connected with the cantonments of the National Army and the National Guard. It is a guaranty of the high character of the professional work that will be done in them, and of the care that the sick soldiers will receive during their training. It is also an index of the patriotism of the best men in the medical profession:

CHIEFS OF MEDICAL SERVICE, CAMP HOSPITALS

NATIONAL ARMY

Camp Devens, Ayer, Mass., Maj. Joseph H. Pratt, Boston, Mass., instructor in medicine, Harvard University Medical School; assistant visiting physician, Massachusetts General Hospital.

Camp Upton, Yaphank, Long Island, New York, Maj. Harlow Brooks, New York City; professor of clinical medicine, New York University Medical College; visiting physician, City Hospital.

Camp Dix, Wrightstown, N. J., Maj. David Bovaird, New York City; assistant professor of clinical medicine, College of Physicians and Surgeons, Columbia University; visiting physician, Presbyterian Hospital.

Camp Meade, Admiral, Md., Maj. Nellis B. Foster, Ann Arbor, Mich., professor of internal medicine, University of Michigan Medical School.

Camp Lee, Petersburg, Va., Maj. Lawrence Litchfield, Pittsurgh, Pa., practicing physician and consultant.

Camp Jackson, Columbia, S. C., Maj. W. W. Herrick, New York City, associate in medicine, College of Physicians and Surgeons, Columbia University, chief of clinic in medicine, Vanderbilt Clinic; assistant attending physician, Roosevelt Hospital.

Camp Gordon, Atlanta, Ga., Maj. Eugene E. Murphey, Augusta, Ga., professor of medicine, Medical Department, University of Georgia.

Camp Sherman, Chillicothe, Ohio, Maj. Dudley D. Roberts, Brooklyn, N. Y., clinical professor of gastro-enterology, Long Island College Hospital; visiting physician, Brooklyn Hospital.

Camp Taylor, Louisville, Ky., Maj. Walter W. Hamburger, Chicago, Ill., assistant professor of medicine, Rush Medical College, University of Chicago; visiting physician, Michael Reese and Cook County hospitals.

Camp Custer, Battle Creek, Mich., Maj. Ernest E. Irons, Chicago, Ill., assistant professor of medicine, Rush Medical College, University of Chicago; visiting physician, St. Luke's and Cook County hospitals.

Camp Grant, Rockford, Ill., Maj. Joseph A. Capps, Chicago, Ill., associate professor of medicine, Rush Medical College, University of Chicago; visiting physician, St. Luke's and Cook County hospitals.

Camp Pike, Little Rock, Ark., Maj. Arthur A. Small, Chicago, Ill., instructor in medicine, Rush Medical College, University of Chicago; visiting physician, St. Joseph's Hospital.

Camp Dodge, Des Moines, Iowa, Maj. Joseph L. Miller, Chicago, Ill., associate professor of medicine, Rush Medical College, University of Chicago; visiting physician, Presbyterian and Cook County Hospitals.

Camp Funston, Fort Riley, Kansas, Maj. Andrew MacFarlane, Albany, N. Y., clinical professor of medicine, Albany Medical College, Union University; visiting physician, St. Peter's Hospital.

Camp Travis, Fort Sam Houston, Texas, Maj. Herbert C. Moffitt, San Francisco, professor of medicine, University of California; physician to University Hospital.

Camp Lewis, American Lake, Washington, Maj. Calvin S. White, Portland, Oregon, assistant professor of medicine, University of Oregon, Medical School; health officer, Portland.

NATIONAL GUARD

Camp Greene, Charlotte, N. C., Maj. Francis W. Palfrey, Boston, instructor in medicine, Harvard Medical School; assistant visiting physician, Boston City Hospital.

Camp Wadsworth, Spartanburg, S. C., Maj. Llewellyn Sale, St. Louis, Mo., instructor in medicine, Washington University Medical School, St. Louis; visiting physician, St. Louis City Hospital.

Camp Hancock, Augusta, Ga., Maj. Frederick J. Barrett, New York, adjunct professor of medicine, Post-Graduate School of Medicine, New York; visiting physician, Post-Graduate Hospital, New York.

Camp McClellan, Anniston, Ala., Maj. William H. Robey, Jr., Boston, Member of Faculty of Harvard Medical School; visiting physician, Boston City Hospital.

Camp Sevier, Greenville, S. C., Maj. Edward H. Goodman, Philadelphia, associate in medicine, University of Pennsylvania; visiting physician, Presbyterian Hospital, Philadelphia.

Camp Wheeler, Macon, Ga., Maj. Richard Weil, New York, professor of experimental medicine, Cornell University Medical School; adjunct visiting physician, Mount Sinai Hospital, New York.

Camp McArthur, Waco, Texas, Maj. Oliver H. Campbell, St. Louis, visiting physician, St. Louis City Hospital, St. Louis; assistant in medicine, Washington University Medical School.

Camp Logan, Houston, Texas, Maj. Josiah N. Hall, Denver, professor of medicine, University of Colorado.

Camp Cody, Deming, N. Mex., Maj., William S. Bigelow, Boston, physician and consultant.

Camp Doniphan, Fort Sill, Okla., Maj. Sidney Strauss, Chicago, assistant professor of medicine, Rush Medical College, Chicago; assistant attending physician, Michael Reese and *Presbyterian* hospitals, Chicago.

Camp Bowie, Fort Worth, Texas, Maj. James C. Greenway, New Haven, Conn., director of department of medical supervision, Yale University, New Haven, *Conn.*

Camp Sheridan, Montgomery, Ala., Maj. James S. McLester, Birmingham, *Ala., professor of medicine*, Graduate School *of* Medicine, University of Alabama; physician in chief, Hillman Hospital.

Camp Shelby, Hattiesburg, Miss., Maj. George H. Lathrope, Morristown, N. J., attending *physician*, Morristown Memorial Hospital.

Camp Beauregard, Alexandria, La., Maj. Birnie J. Guthrie, New Orleans, La., *professor* of clinical *medicine*, Tulane University.

Camp Kearney, Linda Vista, Calif., Maj. Philip S. Chancellor, Santa Barbara, Calif., *practicing* physician and consultant.

BASE HOSPITALS

Fort McPherson, Maj. C. N. B. Camac, New York, assistant professor of clinical medicine, College *of Physicians* and Surgeons, Columbia University, New York; *director of* medical service, Gouverneur Hospital, New York.

Fort Des Moines, *Maj. Herbert H. Frothingham*, Chicago, practitioner of medicine and consultant.

Fort McHenry, Capt. J. *Albert* Chatard, Baltimore, Md., instructor in clinical medicine, Johns Hopkins Medical *School, Baltimore*, Md.

DIAGNOSIS OF CARDIOVASCULAR DISEASES

In *addition to these*, assistants have been assigned to the various *hospitals, with special* training in modern methods *of* diagnosis and *treatment of* cardiovascular diseases, and after a period of *special instruction* with *Dr. Alfred E.* Cohn in *the* Rockefeller Institute, as follows:

Capts. Harold W. Stevens, Pittsburgh; *Albert* Vander Veer, Jr., *New York City*; James *Howard Agnew, Mobile*, Ala.; and Henry Rose Carter, Jr., Baltimore; Lieuts. Julien E. Benjamin, Cincinnati; Hugh K. Berkley, San *Francisco*; *Ernest P. Boas, New York City*; James H. Brown, Colorado Springs, Colo.; Carl R. Comstock, Saratoga *Springs*, N. Y.; W. L. *Freyhoff*, Cincinnati; Charles D. Giddings, New *York* City; Alpheus F. Jennings, Detroit; Berton Lattin, New York City; Frank B. *Lusk, Chicago*; Willard D. Mayer, *Detroit*; William J. Kerr, San Francisco; *Louis H.* Nahum, New York City; Harold E. B. Pardee, New York City; Edward J. *Riley*, New York City; Orville F. *Rogers*, *Jr.*, Dorchester, *Mass.; Truman G. Schnabel*, Philadelphia; S. Calvin Smith, Philadelphia; F. *Janney* Smith, Detroit; Thayer A. Smith, New *York City; Arthur* E. Strauss, St. Louis; Francis C. Tyng, Salt Lake City.

SPECIAL EXAMINERS AND CONTRACT SURGEONS

Since July, special examiners, selected because of their experience and diagnostic skill, have been *conducting the* examination of the troops in the reserve *officers' training* camps, reorganization camps of the regular Army and of the *National* Guard when assembled for mustering into the federal service *in* the larger cities, and are now at work in the thirty-two cantonments of the National Army and the National Guard. *Many of* them are teachers of medicine and physicians to important hospitals, who could not accept commissions because of this obligation, and have *patriotically* volunteered as contract surgeons. Others, *beyond the age limit for commission* in the corps, have embraced this *opportunity* of rendering a service to the country with only *the* rank and *pay* of a first lieutenant, to which contract surgeons are entitled. Their names make it certain that so far as it is humanly possible no man will be forced to undertake military service whose health will be thereby endangered; and *no* man will escape service who is not suffering from actual disease of the heart or vessels. A list of these cardiovascular examiners follows:

Majors *David Boviard, New York City; Thomas D. Coleman, Augusta, Ga.; *Lewis A. *Conner, New York City; James* C. Greenway, New Haven, Conn.; *Josiah* N. *Hall*, Denver; W. W. Hamburger, Chicago; Walter A. Jayne, Denver; Herbert C. Moffitt, San Francisco; and Roger S. *Morris, Cincinati.*

Capts. James H. Agnew, Mobile, Ala.; Ralph C. Brown, Chicago; *S. L. Cash, New York City; *Joseph A. Chatard, Baltimore; Jule B. Frankenheimer, San Francisco; *Milton H. Fussell, Philadelphia; Cary Gamble, Baltimore; *William J. Hammer, New York City; Alpheus F. *Jennings*, Detroit; Oscar E. Lademann, Milwaukee; *John J. McClellan, Chicago; B. S. Oppenheimer, New York City; Ross V. Patterson, Philadelphia; Henry L. Smith, Baltimore; *Gerald B. Webb, Colorado Springs, Colo.; *Gordon Wilson, Baltimore, and Charles C. Wolforth, Philadelphia.

Lieuts. *James R. *Arneill*, Denver; Hugh K. Berkley, San Francisco; **Thomas* F. Ellis, New York City; *Hermann Elwyn, New York City; *Augustus Eshner, New York City; *Harvey M. Ewing, Montclair, N. J.; William J. Kerr, San Francisco; *John T. Kling, Jr., Baltimore; **Geza Kremer*, New York City; *Frank McLean, New York City; John H. *Musser, Philadelphia*; *David Reisman, Philadelphia; *Henry C. Thacher, New York City; Thayer A. Smith, New York City, and Frank N. Wilson, St. Louis.

Contract Surgeons Vanderpoel Adriance, *Williamstown*, Mass.; Arthur P. Beifeld, Chicago; Worth N. *Brown*, Baltimore; *F. R. Burke, Boston; *E. A. Burnham, Boston; Glentworth R. Butler, Brooklyn; Robert J. Carlisle, *New York City*; Thomas A. Claytor, Washington, D. C., *A. T. Downing, Boston; Frederick T. Fahlen, St. Louis; Harold Feil, Cleveland; **Cleveland Floyd*, Boston; *W. B. Ford, Milwaukee; *Hugo* A. Freund, Detroit; Alfred Friedlander, Cincinnati; Joseph C. Friedman, Chicago; Lewis Fox Frissell, New York City; James H. Gibbes, Columbia, S. C.; Charles L. Greene, St. Paul; *Harry W. Goodall, Boston; T. Stuart *Hart, New York City*; George S. Hill, Boston; Tasker Howard, *Brooklyn*; William E. Hughes, Philadelphia; *Henry* Jackson, Boston; Thomas S. Lee, Washington, D. C.; *Donald* Macomber, Boston; *J. D. Madison, Milwaukee; *H. D. McCarty, *Baltimore*; Louis Mendelsohn, Boston; *G. R. Minot, Boston; *T. J. Murphy, Boston; *Lawrence T. Newhall, Boston; *Edward O. Otis, *Boston*; **Arthur J.* Patek, Milwaukee; *Peter J.* Pothuisje, Denver; Thomas I. Simonton, Pittsburgh; Willard J. Stone, Toledo; *W. P. Stubbs, Baltimore; *Lawrence G. *Sykes, Milwaukee*; Arnold S. Taussig, Denver, and J. Gurney Taylor, Milwaukee.

MEN UNDER HALF-TIME CONTRACT

Doctors George Bachmann, Atlanta, *Ga.*; *George S.* Bond, Indianapolis, *Cary Eggleston, New York City; *Howard H. *Mason*, New York City; Martin A. Mortensen, Battle *Creek*, Mich., and *Leander H. Shearer, New York City.

* Tuberculosis examiners also.

COMPLETION OF INTERNSHIP OF COMMISSIONED OFFICERS

The Surgeon-General's Office has issued the following statement relative to interns in the Medical Reserve *Corps*:

When a *regularly* commissioned officer *in* the Medical Reserve Corps *applies for* permission to complete one *year's* hospital service, such *permission* will be granted *by the* Surgeon-General *providing the* exigencies of the service permit. *In* order to continue *on the inactive list* for the completion *of* internship, the officer *concerned will make* formal *application* to the Surgeon-General *of* the *Army*, which shall be accompanied by a statement *from the executive* officer of the hospital *certifying the fact that the appointment* as intern has been made, and the date on which the *internship* commenced. *In* granting permission to continue inactive as above, the following provisions will apply: (*a*) period of internship, in so far as this office is concerned, commences August 1 following graduation of *any year* and terminates July 31 *following*; (*b*) in event *of* termination of service prior to expiration of *one year* allowed, immediate report must be made to the *Surgeon-General* by both the executive officer of the hospital and the *intern*; (*c*) *the* term *internship* is hereby interpreted to mean *one year's* hospital service immediately following graduation and *cannot* be *applied* to hospital service entered into after August 1 *next* succeeding graduation.

Interns who *have* already received appointments in the Medical *Reserve* Corps but who have not accepted them may be *allowed* an opportunity to complete their service *as* interns either by entering the Medical Enlisted Reserve Corps, conformably to the regulations made and provided for the discharge of interns from military service under the selective *service law*, or *by* accepting appointment. *In* the latter case, *application must* be made at once as above provided. Those who *have not already* received commissions in the Medical Reserve Corps and who desire to complete hospital service but who come within the provisions of the selective service *law*, will be obliged to enlist in the Medical Enlisted Reserve Corps.

At the time of application for permission to continue inactive, commissioned officers to whom *this privilege* is granted and who are within the draft age will be supplied with a statement to the effect that they are regularly commissioned and subject to orders from this department, and Form 117, prepared by *the Provost* Marshal-General, and obtainable at the office of the local board, will be signed at this office *if* a copy *is forwarded* with the statement that it is required by the local board. Affidavit forms for such officers have been prepared and are being sent to interns commissioned as officers who desire to complete their internships.

Constitution of Board to Write Medical History of the War

A board constituted to write the medical history of the war consists of Lieut.-Col. *C. C. McCulloch, M. C.*, U. S. Army; Major Fielding Garrison, M. R. C., U. S. Army, *and* Major John S. Fulton, M. R. C., U. S. Army. *This committee* may be addressed at the Army *Medical Museum*, Washington, D. C.

Orders to Officers of the Medical Corps

Col. William O. Owen, M. C., now on duty at the Army Medical Museum, to proceed to Detroit, Mich., for the purpose of inspecting the motion picture laboratory of the Ford Motor Works, and on completion of this duty to return to his proper station.

Lieut. Henry L. Krafft, M. C., to be relieved from duty at the Walter Reed General Hospital, Takoma Park, D. C., and to proceed to Camp Dix, Wrightstown, N. J., and report in person to the commanding general of that camp for duty with the division surgeon.

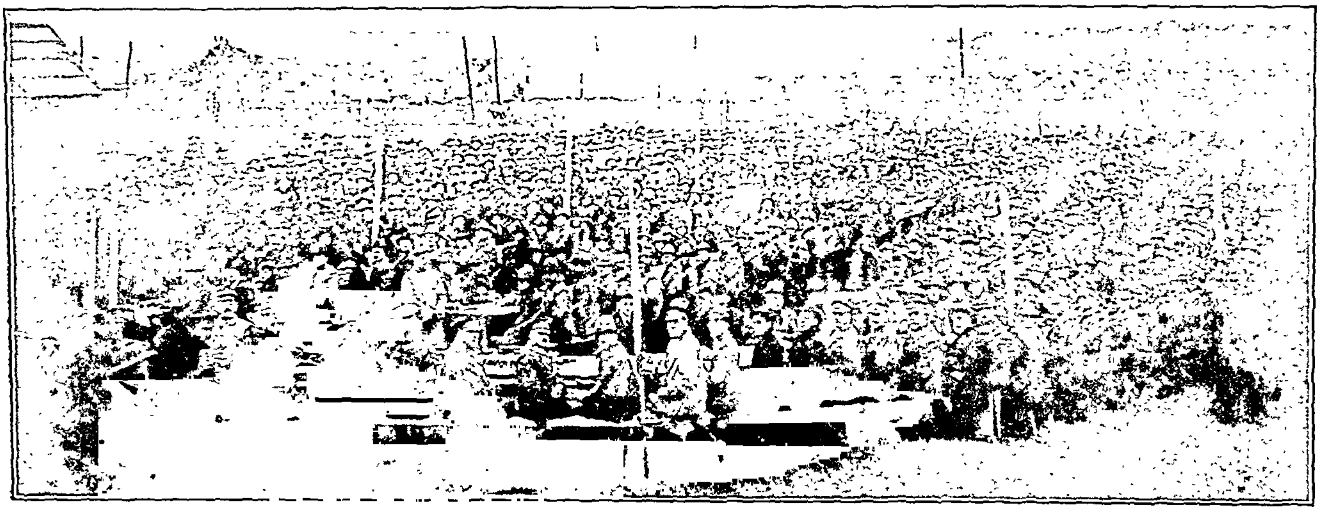
Major Benjamin B. Warriner, M. C., to be relieved from duty at Douglas, Ariz., and to proceed to Mineola, Long Island, N. Y., and report in person to the commanding officer, Hazlehurst Field, Aviation Section, Signal Corps, for duty.

Major Ross H. Skillern, M. C., Pennsylvania N. G., be relieved from his present duty at Camp Sheridan, Montgomery, Ala., and directed to report in person to the commanding general thereof and to the commanding officer of the base hospital for duty in the division of otolaryngology, section of surgery of the head.

Major Thomas D. Woodson, M. C., now in this office, be directed to proceed to the following named places for the purpose of inspecting these sites to determine their degree of availability for use as general hospitals, and on completion of this duty to return to his proper station: Fort Niagara, N. Y; Fort Porter, N. Y.; Fort Ontario, N. Y.; Fort Ethan Allen, Vt.; Madison Barracks, N. Y.; Plattsburg Barracks, N. Y.

First Lieut. Walcott Denison, M. C., on the expiration of sick leave granted him in office orders No. 5403, Surgeon-General's Office, Oct. 9, 1917, be relieved from duty in the office of the Surgeon-General and directed to report in person to the chief surgeon, aviation section, signal corps, for duty in his office, and by letter to the commanding general, aviation section, signal corps, Washington, D. C.

Major Henry B. McIntyre, M. C., New York, N. Y., be directed to proceed to Fort Oglethorpe, Georgia, and report in person to the commandant, Medical Officers' Training Camp, Camp Greenleaf, for duty as instructor.



The barbecue at the meeting of the Association of Military Surgeons at Fort Benjamin Harrison, Indiana. In the background may be seen the evacuation hospital established by Major H. M. Lyle.

Major Kerwin W. Kinard, M. C., be relieved from duty at the base hospital, Camp Sherman, Chillicothe, Ohio, and directed to proceed to Fort Riley, Kan., and report in person to the commandant, Medical Officers' Training Camp, for duty as instructor.

Lieut.-Col. Robert L. Carswell, M. C., be relieved from duty at the Medical Officers' Training Camp, Camp Greenleaf, Fort Oglethorpe, Georgia, and directed to proceed to Fort Sam Houston, Texas, and report in person to the commanding general, southern department, for duty.

Orders to Officers of the Medical Reserve Corps

ALABAMA

To Camp Jackson, Columbia, S. C., for the purpose of making examinations in his specialty, from Phipps Clinic, Baltimore, Md., Lieut. Wilbur L. Heard, Mt. Vernon.

To Camp Meade, Annapolis Junction, Md., for duty, Lieut. Thomas M. McMillan, Jr., Mobile.

To Fort Oglethorpe for instruction, Lieuts. Jacob D. Staples, Camp Hugh; Edward D. McAdory, Cullman; Joseph M. Weldon, Tallassee; Walter E. Allen, Ward; from Motor Ambulance Supply Depot, Louisville, Ky., Charles W. Williams, Cherokee.

To Newport News, Va., for duty with 303d Stevedore Regiment, from Fort Oglethorpe, Capt. Mack Rogers, Birmingham.

To his home and return to the inactive list of the Medical Reserve Corps of the Army on account of being physically disqualified for active service, Lieut. Horace L. McWhorter, Collinsville.

Honorably discharged, Lieuts. Joseph M. Theringer, Mobile; from the Medical Reserve Corps on account of holding a commission in the National Guard, Frank V. Meriwether, Samson, Ala.

ARKANSAS

To Camp Funston, Fort Riley, Kan., for duty, from Medical Officers' Training Camp, Lieut. Samuel G. Boyce, Little Rock.

To Camp Pike, Little Rock, Ark., from Camp Beauregard, Alexandria, La., for duty with the First Arkansas National Guard, Lieut. James E. Phillips, Eureka Springs.

To Fort Oglethorpe for instruction, Lieuts. John E. Burns, Black Rock; Mathew A. Bizzell, Doddridge; James E. Johnson, Fort Smith; Raphael W. Steele, Gentry; Mahlon D. Ogden, Geyer C. Wood, Little Rock; Everett N. Lipe, Scranton; John M. Bearden, Sonora.

To Washington University, St. Louis, Mo., for three weeks' intensive training, Lieut. Sydney J. Wolfermann, Ft. Smith.

CALIFORNIA

To Camp Cody, Deming, N. M., for duty, Lieut. Clarence W. Dodge, Los Angeles.

To Camp Lewis, American Lake, Wash., for duty, Lieuts. Robert W. Brace, Modesto; John E. Paulson, San Quentin.

To Camp Mills, Garden City, L. I., for duty with First Colorado Field Hospital, from Camp Baldwin, Denver, Colo., Lieut. Paul A. Opp, Los Angeles.

To Fort Oglethorpe for instruction, Lieut. John H. Woolsey, San Francisco.

To Los Angeles, for a course of instruction in military roentgenology, Lieut. John P. Byrnes, Oakland.

To their homes and return to the inactive list of the Medical Reserve Corps, Major James R. Moore, Los Angeles; Lieut. Charles H. Bailey, San Francisco.

CANAL ZONE

To Mineola, L. I., for duty with the Aviation Section, from duty at Balboa, Canal Zone, Capt. Edward P. Beverly, Cristobal.

COLORADO

To Dodge, Iowa, for duty in his specialty, from duty at Fort Douglas, Utah, Lieut. Philip Work, Pueblo.

To Camp Funston, Fort Riley, Kan., for duty, from Medical Officers' Training Camp, Lieuts. Floyd C. Turner, Stoneham; Aubert Durnell, Strong.

To Camp Robinson, Sparta, Wis., for duty with the 8th Field Artillery, Lieut. Robert L. Zaegel, Denver.

To Fort Logan, Colo., for duty, Major William W. Grant, Denver.

To Fort Oglethorpe for instruction, Lieuts. William S. Brown, Denver; James M. Shields, Grand Junction; Ernest G. Edwards, La Junta.

To his home and return to the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, from duty at Fort Oglethorpe, Lieut. Harry B. Sobernheimer, Meeker.

CONNECTICUT

To Fort McHenry, Md., for duty in the laboratory, Lieut. Abraham L. O'Shansky, New Haven.

To Fort Oglethorpe, for instruction, Lieut. Owen O'Neill, Willimantic.

To Neurological Institute, New York, N. Y., for intensive study in his specialty, Lieut. Harold A. Bancroft, Hartford.

Honorably discharged on account of being physically disqualified, Lieut. Albert A. Wheelock, New Canaan.

DELAWARE

To Fort Oglethorpe for instruction, Lieut. John B. Rutherford, Wilmington.

DISTRICT OF COLUMBIA

To Camp Hancock, Augusta, Ga., from Fort Oglethorpe, for duty in the division of plastic and oral surgery, section of surgery of the head, Lieut. Oliver C. Cox, Washington.

To Camp Logan, Houston, Tex., for duty as a member of a board of medical officers for tuberculosis examination, Lieut. Richard M. Little, Washington

To Camp Wheeler, Macon, Ga., 31st Division, *for duty as member of* a board of medical officers for tuberculosis examination, from Fort Myer, Va., Lieut. Frederick Sohon, Washington.

To Cornell Medical College, New York, for a course of instruction in military roentgenology, Lieut. Stuart C. Johnson, Washington.

To Fort Oglethorpe for instruction, Lieuts. True S. Burgess, Albert E. Pagan, David G. Sampson, James S. Taylor, Washington.

To Langley Field, Hampton, Va., for temporary duty in connection with aviation and upon completion of this duty to return to their proper station, Majors Edward G. Seibert and William H. Wilmer, Washington.

To Mineola, L. I., from Washington, D. C., for temporary duty in connection with the Aviation Service of the Army, Majors William H. Wilmer and Edward G. Seibert, Washington.

To Rockefeller Institute, New York, for a course of instruction and upon completion of this course to return to his home and to the inactive list of the Medical Reserve Corps, Major James F. Mitchell, Washington.

FLORIDA

To Camp Meade, Annapolis Junction, Md., *for duty with 23rd* Engineer Regiment, from Fort Oglethorpe, Lieut. Adam C. Walkup, McIntosh.

To Fort Oglethorpe for instruction, Capt. Thomas A. Neal, Sanford; Lieut. Henry P. Bevis, Arcadia.

To Walter Reed General Hospital, Takoma Park, D. C., for duty as surgical assistant, Lieut. Maurice D. Barnette, Watertown.

To Washington, D. C., and report in person to the Surgeon-General of the Army for duty in his office, Major Thomas W. Salmon, New York City.

To Washington University, St. Louis, Mo., for three weeks' intensive training, Capt. Samuel L. Fisher, Brooklyn; Lieut. John L. Edwards, Hudson; from Fort Slocum, N. Y., and upon completion to return to his proper station, Lieut. Richard T. Atkins, New York City.

To his home from duty at Camp Merritt, N. J., and return to the inactive list of the Medical Reserve Corps of the Army on account of being physically disqualified for active service, Capt. Daniel W. Wynkoop, Babylon.

To his home and the inactive list of the Medical Reserve Corps from duty at Fort Monroe, Va., on account of being physically disqualified for active service, Lieut. Edward D. Fraser, Brooklyn.

NEW MEXICO

To Camp Cody, Deming, N. M., for duty, Capt. Henry R. Brown, Albuquerque.

To Camp Lewis, American Lake, Wash., for duty as tuberculosis specialist and member of the Army Medical Staff, Capt. David C. Twichell, Albuquerque.

NORTH CAROLINA

To Camp Gordon, Atlanta, Ga., for duty as chief of the surgical service, Capt. James S. Brown, Hendersonville.

To Camp Greene, Charlotte, N. C., and report in person to the commanding general and to the commanding officer of the base hospital for duty in the division of plastic and oral surgery, section of surgery of the head, Lieut. Charles W. Banner, Greensboro.

To Camp Sevier, Greenville, S. C., for duty in connection with orthopedic work, Lieut. Robert A. Moore, Charlotte.

To Fort Moultrie, S. C., for duty, Lieut. Mont R. Farrar, Greensboro.

To Fort Oglethorpe for instruction, Lieuts. Carl W. Bell, Raleigh; Edgar P. Norfleet, Roxobel; Thomas H. Royster, Tarboro; John B. Powers, Wake Forest; William T. Ruark, Wilmington.

To Richmond Medical College for a course in military roentgenology, Lieut. Henry C. Turlington, Cooper.

To Walter Reed General Hospital, Takoma Park, D. C., for duty, Lieut. Matthew L. McCorkle, Newton.

To his home and return to the inactive list of the Medical Reserve Corps of the Army, on account of being physically disqualified, Lieut. Joseph R. Shull, Cliffside.

NORTH DAKOTA

To Camp Dodge, Des Moines, Ia., for duty, Lieuts. Julius O. Arnson, Bismarck; Mark Mizener, Bowman.

To Fort Oglethorpe for instruction, Lieut. Howard L. Saylor, Cogswell.

To State Psychopathic Hospital, Ann Arbor, Mich., for intensive study in his specialty, Capt. Adolphus W. Guest, Jamestown.

OHIO

To Camp Bowie, Fort Worth, Tex., for duty, Lieut. Douglas R. Venable, Cleveland.

To Camp Cody, Deming, N. M., for duty, Capt. Henry R. Brown, Chillicothe.

To Camp Funston, Fort Riley, Kan., for duty, from Medical Officers' Training Camp, Lieuts. William M. Goff, Marysville; Myron Hanna, Scott.

To Camp Sherman, Chillicothe, O., for duty, Capt. Elmore E. Adel, Columbus; Lieuts. Daniel C. Handley, Cincinnati; George F. Glass, Cleveland; Edward D. Harper, Guysville; for temporary duty, Anthony Matuska, Cleveland; Clark E. Sharp, Columbus.

To Fort Oglethorpe for instruction, Capt. Paul G. Woolley, Cincinnati; Claude D. Hamilton, Canton; Charles G. LaRocco, Lewis A. Oster, Cleveland; Harold K. Mouser, Marion; Neville E. Stewart, Wauseon; William McG. Blaine, Youngstown.

To Fort Sheridan, Ill., for duty, Capt. Joseph S. Rardin, Portsmouth.

To Jefferson Barracks, Mo., for duty, Capt. Harry T. Miller, Springfield.

To Washington University, St. Louis, Mo., for three weeks of intensive training, from Allentown, Pa., Capt. Frederick J. Bierkamp, Youngstown.

OKLAHOMA

To Camp Bowie, Fort Worth, Tex., for duty, from Base Hospital, Lieuts. George M. McVey, Verden; Will W. Jackson, Vinita.

To Camp Doniphan, Fort Sill, Okla., for duty, Lieut. John B. Haggard, South Coffeyville.

To Camp MacArthur, Waco, Tex., for duty in charge of the division of brain surgery, section of surgery of the head, Capt. Robert M. Howard, Oklahoma.

To Camp Merritt, N. J., for duty, from Army Medical School, Lieut. Davy Lewis Garrett, Altus.

To Camp Vail, Little Silver, N. J., for duty with the 11th Telegraph Reserve Battalion, Lieut. Willis K. West, Oklahoma.

To Fort Oglethorpe for instruction, Lieuts. Samuel T. Campbell, Anadarko; James R. Bost, Cashion; Roland R. Culbertson, Hoyt.

To Kansas City, Mo., for course of instruction in military roentgenology from Ft. Riley, Lieut. Daniel E. Little, Eufaula.

To report in person to the commanding general, Camp MacArthur, Tex., for duty in the surgical service, Lieut. William G. Hushund, Gould.

OREGON

To Camp Dodge, Des Moines, Ia., from Fort Riley for duty, Capt. Joseph A. Pargon, Portland.

To Camp Lewis, American Lake, Wash., for duty, Lieut. Arthur C. McCown, Cove.

To Fort Oglethorpe for instruction, Lieut. Harry M. Bouvy, La Grande.

To Washington University, St. Louis, Mo., for a three weeks' course of intensive training, Capt. Justin M. Waugh, Hood River.

To report in person to the commanding general, Camp Lewis, American Lake, Wash., for duty as assistant in the surgical service, Capt. Paul Rockey, Portland.

PENNSYLVANIA

To Buffalo, N. Y., Rochester, N. Y., Barre, Vt., Manchester, N. H., Brooklyn, N. Y., for duty in connection with the Medical Reserve Corps of the Army and on completion of this duty to return to his proper station, Major Henry D. Jump, Philadelphia.

To Camp Dix, Wrightstown, N. J., for duty, Lieut. James E. James, Plymouth.

To Camp Dodge, Des Moines, Ia., from Fort Riley, for duty, Lieut. William H. Kober, Pittsburgh.

To Camp Grant, Rockford, Ill., for duty with 35th Engineer Regiment, from Fort Oglethorpe, Lieut. Clark H. Yeager, Wilkes-Barre.

To Camp Hancock, Augusta, Ga., for duty in the surgical service, after completion of course of instruction at Rockefeller Institute, New York, N. Y., Capt. David H. Boyd, Pittsburgh; for duty as member of board of medical officers for tuberculosis examination, from Walter Reed General Hospital, Lieut. William G. Spalding, Cresson.

To Camp Lee, Petersburg, Va., for duty, Lieuts, Llewellyn I. Thomas, Burnham; Charles B. Dotterrer, Boyertown; Adam M. Robinhold, Hamburg; for temporary duty, Herbert F. Kenny, Pittsburgh.

To Camp Meade, Annapolis Junction, Md., for duty, Capt. Edward M. Haley, Blossburg; Lieut. Charles S. Fox, Philadelphia.

To Camp Mills, Garden City, L. I., for duty at Base Hospital, from duty at Field Hospital No. 3, Lieuts. George H. Tibbins, Beach Creek; for duty, Lieut. William W. Van Dolson, Philadelphia.

To Camp Pike, Little Rock, Ark., for the purpose of examining troops in his specialty, Capt. Percy DeLong, Cynwyd.

To Camp Sevier, Greenville, S. C., for duty in the Division of otolaryngology, section of surgery of the head, from duty at Base Hospital, Major George M. Coates, Philadelphia.

To Camp Vail, Little Silver, N. J., for duty, Lieut. John V. Kearney, Philadelphia.

To Camp Wheeler, Macon, Ga., for regimental duty, from Fort Oglethorpe, Lieuts. Nicholas E. Abbaticohio, Bert F. Ober, Latrobe; Charles M. McCoy, Lewistown; Amos K. DuBell, William H. McKeever, Philadelphia; Frank R. Wheelock, Scranton.

To Chicago, Ill., for the purpose of conferring with the State Committee of National Defense Medical Section, and upon completion of this duty to return to his proper station, Major Henry D. Jump, Philadelphia.

To Fort Oglethorpe, Ga., for instruction, Lieut. G. H. Schlenker, Cazenovia.

To Neurological Institute, New York City, for a course of intensive training in his specialty, Lieut. Smiley Blanton, Madison.

To Washington University, St. Louis, Mo., for three weeks' intensive training, from Fort Riley, and upon completion to return to his proper station, Capt. Gustaf R. Egeland, Sturgeon Bay.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Bill Compromised.—For work done in connection with the threatened epidemic of spinal meningitis in the naval training camp at Balboa Park, San Diego, the city health authorities rendered a bill for $1,500 against the United States government. The bill occasioned considerable discussion by the members of the health board and the naval authorities. It was finally compromised by the government paying the city $650.

Personal.—Dr. T. Brailsford Robertson, professor of biochemistry and pharmacology in the University of California, has donated to the university his patent rights in the product "Tethelin," isolated from the anterior lobe of the pituitary body and believed to control growth of cells, and to be capable of accelerating repair in slowly healing wounds. All profits resulting from this discovery are to constitute an endowment, the income to be applied to medical research.——Dr. Alfred E. Banks, health officer of San Diego, has resigned and resumed private practice. He has recommended that Dr. William W. Crawford be appointed his successor.——Dr. Ralph W. Nauss, Fresno, the newly appointed state district health officer, has established headquarters for the central district in Fresno.

GEORGIA

Personal.—Dr. William L. Funkhouser has moved from Rome to Atlanta, and will devote himself exclusively to the treatment of children.——Dr. John E. Toole has been elected mayor of Bainbridge.——Dr. Albert Fleming, Waycross, has been reappointed a member of the State Board of Examiners.

Tuberculosis Clinic in Savannah.—The Central Council of Charitable and Philanthropic Organizations of Savannah has advocated the immediate establishment of a free tuberculosis clinic in Savannah, and a committee, whose chairman is Rev. S. B. McGlohan, will act with a committee from the Georgia Medical Society, headed by Dr. James O. Baker, for the accomplishment of this much needed charity.

IDAHO

Personal.—Dr. Joseph H. Murry, surgeon of the Oregon Short Line Railroad, Nampa, has resigned, and Dr. Frank B. Smith has been appointed his successor.

Contract Let for Sanatorium.—The contract for the construction, completion and equipment of the main building of the Idaho State Sanatorium, Nampa, has been awarded for $23,800.

ILLINOIS

Personal.—Dr. Alice Barlow Brown, Winnetka, has arrived at Toulouse, France, where she is to establish a free dispensary for women and children which is supported by the women of Winnetka, and the American Fund for French Wounded.——Dr. Max C. Hawley, Elgin, has been appointed superintendent of the Watertown State Hospital.——Dr. George Parker, medical director of the Peoria Life Insurance Company, has entered on the duties of commissioner of health of Peoria, succeeding Dr. Emmett A. Garrett, called to war service.——Dr. Emil Bunta, Chicago, has been appointed a member of the staff of the Oak Forest Infirmary.

INDIANA

New Surgeries Opened.—The north annex and new surgeries of the Methodist Episcopal Hospital, Indianapolis, were formally dedicated, October 14 and 15. The north wing of the hospital was completed last year, but had never been formally dedicated. The new surgical operating rooms have just been completed at a cost of $40,000.

Sanatorium To Do Outpatient Work.—The directors of the Marion County Medical Society for the Prevention of Tuberculosis have decided to buy an automobile for the use of the outpatient department of Sunnyside Sanatorium. This will enable Miss Gaskill, nurse at the head of this department, to visit tuberculosis patients in all parts of the county in order to advise and keep in touch with them after their discharge from the sanatorium.

Personal.—Dr. Abner H. Shaffer, Huntington, fell in his home, October 5, fracturing his hip.——Dr. Lewis P. Drayer, Fort Wayne, has been appointed secretary of the city health board, succeeding Dr. John H. Gilpin, resigned to enter the military service.——Dr. Daniel F. Randolph, Waldron, was seriously injured recently in an automobile accident in Van Buren Township.

Section Officers.—At the recent meeting of the Indiana State Medical Society, Dr. Charles P. Emerson, Indianapolis, was elected chairman of the medical section, and Dr. Jane M. Ketcham, Indianapolis, secretary. Dr. Ludson Worsham, Evansville, was elected chairman of the surgical section, Dr. Goethe Link, Indianapolis, vice chairman, and Dr. Howard O. Shafer, Rochester, secretary.

Memorial to Dr. Bobbs.—At Indianapolis, October 11, in the medical section of the new $6,000,000 library building, a bronze tablet was erected in honor of the memory of Dr. John Stough Bobbs, a pioneer surgeon of Indiana. In the dedication of the tablet, addresses were made by Dr. Henry Jameson, of the Medical Department of the University of Indiana, formerly dean of the Indiana Medical College, founded by Dr. Bobbs; by Louis Howland, editor of the Indianapolis *News*, and by Dr. Hillary Gobin, president of De Pauw University, who was for three years secretary to Dr. Bobbs. Dr. Bobbs was born in 1809 and died in 1870. In addition to the founding of the Indiana Medical College in which he was a teacher until his death, he was also one of the founders of the state medical society, donated a medical library to the physicians of Indiana, endowed a dispensary which is now the Indianapolis City Dispensary, and was a brigade surgeon during the Civil War, and helped to carry from the field and care for wounded soldiers at the Battle of Bull Run. The memorial addresses credited Dr. Bobbs with being one of the great surgeons of America. The bronze tablet, executed by Gutzon Borgulum, is 6 feet by 3½ feet in size, bears in bas relief the figure of Dr. Bobbs, and the following inscription: "Illustrious Surgeon, Patriotic Citizen, Self-Sacrificing Benefactor, Servant of God through Service to Mankind. First to perform the operation of cholecystotomy." That Dr. Bobbs was the originator of the operation of opening the gallbladder is fully attested. The work of securing funds and carrying out the establishment of the memorial was in the hands of a committee consisting of Drs. Henry Jameson, Alembert W. Brayton, William N. Wishard, John H. Oliver and Frank B. Wynn, some of the members having been associates of Dr. Bobbs.

MARYLAND

Typhoid Cases Increase.—Twenty-six new cases of typhoid fever were reported to the Health Department of Baltimore during the week. There were four deaths from the disease. The *Health Bulletin* also reports 189 deaths in Baltimore, for the week, and 300 births.

Personal.—Dr. Archibald C. Harrison, director of the University of Maryland Base Hospital Unit, was recently operated on by Dr. Thomas S. Cullen in St. Joseph's Hospital for acute abdominal trouble.——Miss Mary L. Kelly, assistant superintendent of nurses of the Health Department of Baltimore, has been appointed assistant bacteriologist of the health department.——Dr. Harry F. Shipley, Granite, was seriously injured, September 13, by the overturning of his automobile near Gwynn Oak; he sustained a fracture of the clavicle and two ribs.——Dr. Karl H. Van Norman, formerly assistant superintendent of Johns Hopkins Hospital, who resigned in November, 1915, for war service with the Canadian forces and was placed in charge of a base hospital in Ramsgate, England, and later was made assistant chief of the Canadian hospitals in England, has returned to this country to recuperate, and is in temporary charge of the Canadian recruiting station at Minneapolis.

MASSACHUSETTS

Health Department Moves.—New headquarters have been opened for the state department of health on the fifth floor of the state house, and the water, sewerage, food and drug laboratories are on the same floor.

Personal.—Dr. Philip Castleman has been appointed deputy health commissioner of Boston, and Dr. Honore Van de Velde, assistant director of pathologic laboratories in the health department.——Dr. M. Victor Safford, U. S. P. H. S., has been appointed epidemiologist of the Boston Health

Department.——Lieut. Harry R. Coburn, M. R. C., in charge of the men's department of the Tewksbury State Hospital, was given a farewell dinner, September 7, at which he was presented with a wrist watch.——Dr. Frank H. Carlisle, Wrentham, assistant superintendent of the Norfolk State Hospital, Pondville, for ten years past, has accepted an appointment as medical director of the Massachusetts Farm, Ridgewater.

MICHIGAN

New Officers.—At the annual meeting of the Wayne County Medical Society, held in Detroit, Dr. Warren L. Babcock was elected president, Dr. Clarence E. Simpson, vice president; Dr. Raymond C. Andries, secretary, and Dr. William H. Morley, treasurer.

State Board Members.—The following appointments are announced by the governor for membership in the Michigan State Board of Registration in Medicine: Dr. Guy L. Conner, Detroit, to succeed Dr. Colonel B. Burr, Flint; Dr. William S. Shipp, Battle Creek, to succeed Dr. William T. Dodge, Big Rapids, and Drs. Albertus Nyland, Grand Rapids, and Nelson McLaughlin, Lake Odessa, to succeed themselves.

Personal.—Dr. Edwin R. Vander Slice, Lincoln, for two years physician for the state board of health tuberculosis survey, has been appointed executive secretary of the Michigan Antituberculosis Association.——Dr. Eloise Walker, Binghamton, N. Y., has been appointed physician to the University of Michigan, health service, succeeding Dr. Elsie S. Pratt, Denver.——Dr. Richard M. Olin, secretary of the state board of health, Caro, has moved to Lansing.——Application has been made for a sanitary commission to examine Dr. Ralph E. Gustin, Detroit, who is said have been recently sentenced to serve one year for manslaughter.——Dr. William C. Bell has been appointed police surgeon of Detroit, succeeding Dr. Griffith A. Thomas, resigned to take command of an ambulance company at Fort Sherman, Chillicothe, Ohio.

MINNESOTA

Health League Trains Nurses.—The Minnesota Public Health Association announced that it will expend $8,000 for the training of graduate nurses to do visiting work in towns and rural communities.

Personal.—Dr. George E. Putney, Paynesville, has been appointed a member of the State Board of Medical Examiners, succeeding Dr. Pierre C. Pilon, Paynesville, resigned to enter the Army.——Dr. Arthur T. Laird, superintendent and secretary of the Nopeming Sanatorium, Duluth, has been appointed by the Rockefeller Foundation to do tuberculosis work in France.

Hospital Items.—St. Peter's new hospital, known as the Field Hospital and Sanitarium, was opened for patients, October 1. The formal opening took place a week later. The building at present accommodates fifteen patients, and is under the charge of Dr. Merton Field.——Dr. Philip E. Stangl, formerly of St. Cloud, has assumed charge of the Paynesville Hospital.——Work on the new Itasca County Hospital, Grand Rapids, has been begun, and under the terms of the contract the building must be completed before April 1, 1918.

NEW YORK

Oppose Institution at Lake Mohansic.—For several days the joint legislative committee has been taking testimony in order to reach a decision as to the disposition to make of the 1,000-acre site bought for a state hospital and home for juvenile delinquents. Protests against having any buildings on this site have been made by the commissioner of the board of water supply and representatives of the New York Academy of Medicine, the real estate board, the Safety First Society, the Central Mercantile Association, and by a number of other civic bodies.

New York City

Carpenter Lecture.—The Wesley M. Carpenter lecture was delivered at the New York Academy of Medicine, October 18, by Dr. William J. Mayo, Rochester, Minn., on "The Relation of the Spleen to Some Obscure Clinical Phenomena."

To Organize Vital Economics Work.—John R. Murlin, for eight years assistant professor of physiology in the Medical School of Cornell University, has been appointed director of the new Department of Vital Economics [illegible] of Rochester. This department has been endowed with funds made available by the will of Lewis E. Ross.

Surgical Conference.—Professor Campbell announces that a surgical conference will be held in the amphitheater of Long Island College Hospital, Brooklyn, every Wednesday afternoon at 3 o'clock. The subject for October 10 was "Hernia."

Draft Physician Punished.—Dr. Henry Seligman, Brooklyn, is said to have been convicted, October 3, of a conspiracy to cause the evasion of the selective draft law, and to have been sentenced to two years' imprisonment in the United States Penitentiary, Atlanta, and to pay a fine of $3,000.

New School for Nurses.—Largely as a result of the appeal of the Council on National Defense that all hospitals in the country increase their educational facilities for training nurses, Bellevue Hospital School for Training Nurses has opened a school for students who do not live at the hospital. There will be no tuition charge, and textbooks and uniforms will be furnished to applicants. The training will cover forty-eight hours each week. The students must have a high school or college education.

Merger of Three Hospitals Planned.—At a conference recently called by Felix M. Warburg and attended by representatives of various city hospitals, plans were considered for merging the three large Jewish hospitals of the Bronx. The plan calls for the erection of a great central hospital building in place of the three separate institutions. It was proposed that a building should be erected to cost at least $500,000 and to accommodate 300 patients. The plan also includes the establishment of dispensaries in different parts of the Bronx. Resolutions were adopted authorizing the appointment of a committee of those interested in the work to make a survey and to work out definite plans.

Personal.—Dr. Isadore Rosen has been appointed instructor in syphilology in the College of Physicians and Surgeons in the City of New York.——Dr. Louis R. Harris, director of the Bureau of Preventable Diseases, has been appointed successor to Dr. Bertram H. Waters, resigned.——Dr. Chester L. Carlisle, formerly senior assistant physician to the King's Park State Hospital, Long Island, has been appointed and has assumed office as superintendent of the Division of Mental Defects and Delinquency of the State Board of Charities, with office at the capital, Albany.——Dr. William G. Bissell, Buffalo, has been elected vice president of the Federated Alumni Association of the University of Buffalo.——Dr. James L. Gallagher, Buffalo, has been reelected supreme medical examiner of the Ancient Order of Foresters for the Atlantic, central and southern states.

OHIO

Personal.—Dr. Allen W. Freeman, U. S. P. H. S., took office, October 1, as the first commissioner of health of Ohio.——Dr. Joseph W. Lehr, Wooster, suffered severe injuries in a collision between an automobile and the buggy in which he was riding, September 30.——Dr. J. Sumner Teter has been appointed city epidemiologist at Toledo, succeeding Dr. Thomas L. Ramsey, resigned.——Dr. Oscar H. Sellenings has resigned as a member of the Columbus Board of Health.——Dr. DeWitt T. McGriff, Lima, has been appointed coroner of Allen County, succeeding Dr. Virgil H. Hay, resigned to enter the military service.——Dr. Leo S. Talaska has been appointed city physician of Toledo, succeeding Dr. J. Sumner Teter.——Dr. William E. Pricer, Ironton, and family have gone to St. Petersburg, Fla.

PENNSYLVANIA

Philadelphia

Personal.—Dr. Thomas McCrae, professor of medicine in Jefferson Medical College, who has been in charge of a large military hospital in England, has returned home and resumed his practice and teaching in Jefferson College and Hospital.——Dr. J. Clarence Keeler has been made assistant professor of otology in Jefferson Medical College.

Army Tuberculosis Unit.—This city has furnished a tuberculosis unit to the government. Twelve experts on diagnosis and treatment have been ordered to proceed to Camp Dix, Wrightstown, to examine the 47,000 drafted men. The physicians who make up this unit are: Drs. Henry R. M. Landis, Charles M. Montgomery, Joseph P. Walsh, Alexander Heron Davisson, Robert Shelmerdine McCombs, Frank A. Craig, Clarence D. Smith, J. Isadore Kaufman, John J. Robrecht, Clinton Foltz, Elmer H. Funk, all of Philadelphia, and Marcus W. Newcomb, Browns Mills, N. J.

Substitutes for Doctors in War Service.—Drs. William W. Keen, George A. Knowles, James T. Rugh, George D. Fussell and Frederick P. Henry, secretary, 114 South Eighteenth Street, the committee to procure substitutes for physicians ordered in service requests all who are going to the front to notify the secretary of the committee of the names and residences of those who are to take charge of their practice during their absence. In case they have difficulty in procuring substitutes, the committee will be glad to assist them in making such arrangements. The committee would suggest to doctors leaving for the front that they inform their patients who their substitutes are and post on the doors of their offices the names and residences of such substitutes.

WEST VIRGINIA

Personal.—Drs. Robert U. Drinkard, John W. Gilmore, Andrew J. Wilson and Charles M. Truschel, Wheeling, have been selected as members of the visiting staff of the View Point Sanitarium, Wheeling.

Semi-Centennial of Medical Society.—The West Virginia State Medical Association held its fiftieth annual meeting at Fairmont, October 2 to 4, under the presidency of Dr. Joseph E. Rader, Huntington. Berkeley Springs was selected as the next place of meeting, and the following officers were elected: president, Dr. Samuel R. Holroyd, Athens; vice presidents, Drs. Charles O'Grady, Charleston; William J. Judy, Belleville, and Charles W. Waddell, Fairmont; secretary, Dr. J. Howard Anderson, Marytown; treasurer, Dr. Hugh G. Nicholson, Charleston; counsellors, first district, Dr. Henry R. Johnson, Fairmont; second district, Dr. Theodore K. Oates, Morgantown; third district, Dr. Chester R. Ogden, Clarksburg; fourth district, Dr. George D. Jeffers, Parkersburg; fifth district, Dr. James E. McDonald, Logan; sixth district, Dr. Horace L. Goodman, McKendree; delegate to the American Medical Association, Dr. F. LeMoyne Hupp, Wheeling, and editor of the journal of the association, Dr. James R. Bloss, Huntington.

WISCONSIN

Society Moves.—The Milwaukee Medical Society has moved into its new quarters in the Colby-Abbott building, and has transferred its library and reading rooms to the new home. The rooms were formally dedicated, October 7.

Personal.—Dr. Frederick M. Harris has resigned as full-time health commissioner of Fond du Lac, and director of the Fond du Lac Cooperative Laboratory.——Dr. Lewis J. Daniels has been appointed health commissioner of Milwaukee, succeeding Dr. George C. Ruhland, who has entered the United States service.

Hospital Notes.—Through the efforts and generosity of Dr. John G. Meachem, the establishment of a children's hospital in Racine has been made possible. Dr. Meachem has purchased a house south of the maternity home on Wisconsin Street, and has given it to St. Luke's Hospital and the Alice Horlick Hospital for a term of years, free of rent and taxes. The building will accommodate seventeen patients.——Sunny Rest Sanitarium, erected four years ago by Racine County at a cost of $35,000, is found to be in need of immediate repairs which will cost more than $5,000.

State Medical Society Meeting.—The State Medical Society of Wisconsin held its annual meeting in Milwaukee, October 3 to 5, under the presidency of Dr. Hoyt E. Dearholt, Milwaukee. The following officers were elected: president, Dr. Gustave Windesheim, Kenosha; vice presidents, Drs. Oscar Lotz, Milwaukee; Thomas W. Nuzum, Janesville, and Karl W. Doege, Marshfield; secretary, Dr. L. Rock Sleyster, Waupun (reelected); treasurer, Dr. Sidney S. Hale, Ripon (reelected); a delegate to the American Medical Association, Dr. Charles H. Lemon, Milwaukee; alternate, Dr. Wilson Cunningham, Platteville, and counsellor of the ninth district, Dr. Joseph F. Smith, Wausau; Dr. Louis M. Warfield, Milwaukee, was elected president, and Dr. Joseph S. Evans, Madison, secretary of the medical section; Dr. Edward W. Quick, Milwaukee, president, and Dr. Daniel Hopkinson, Milwaukee, secretary of the surgical section, and Dr. Sidney S. Hall, Ripon, president, and Dr. Joseph J. Bellin, Green Bay, secretary of the eye, ear, nose and throat section.

CANADA

Personal.—Major William John O. Malloch, Toronto, who returned to England from Saloniki with the Toronto University Base Hospital, has been appointed surgeon-in-chief of the Ontario Military Hospital, Orpington, England.——Lieut.-Col. Thomas Bedford Richardson, Toronto, who has been medical officer to the British-Canadian War Mission, Chicago, has been recalled to Canada, and has been appointed to the staff of the Canadian Pension Board at Ottawa.——Lieut.-Col. P. Walter H. McKeown, Toronto, overseas for over two years, is temporary O. C., Kitchener Hospital, Brighton, England.——Major Donald McGillivray, Toronto, on three months' leave of absence, has not yet fully recovered his health as to permit him to return to England for hospital duty.——Major William J. Clark, Toronto, of the Ontario Military Hospital, Orpington, England, is home on three months' leave of absence.——Hon. Dr. William J. Roche, Minnedosa, Manitoba, who was a member of the late Borden government, has been appointed head of the Canadian Civil Service Commission, but at the present time is in a hospital, seriously ill.——Capt. Brefney R. O'Reilly, Toronto, will accompany the Canadian and American aviators to Texas for winter training. Dr. O'Reilly is medical officer to the Canadian Flying Corps.

Canadian Military Hospitals Commission.—There are now fifty-seven institutions operated directly by the Canadian Military Hospitals Commission, fourteen others at which definite accommodations are available, apart from the hospitals for the insane, and twenty-three hospitals where men may be sent for active treatment.——The commission has under control sixteen hospital cars for transportation of the men from hospital ships to their inland destination. It is expected from 1,200 to 1,500 soldiers will now be returning every month.——Arrangements have been made recently whereby the Canadian Army Medical Corps contributes to the medical service of the commission. The following are the special classes, including specialists, in the following branches: general practice; tuberculosis; orthopedics; mental diseases; eye, ear and throat diseases; dental; massage; electrical treatment; physical drill, and rheumatic treatment.——The Oakhill Military Convalescent Hospital, St. Catherines, Ont., is specially assigned for rheumatic cases. British Columbia has several; Winnipeg, one.——There are two classes of mental disability. The Ontario Military Hospital at Coburg, Ont., will be retained entirely for shell-shock cases, and arrangements have been made to open at Newmarket, Ont., an institution for the insane.——The commission only has one factory thus far for the manufacture of artificial limbs, that in North Toronto, but in the near future other manufactories will be established in different parts of Canada.

GENERAL

Eye, Nose and Throat Specialists to Meet.—The twenty-second annual meeting of the American Academy of Ophthalmology and Oto-Laryngology will be held in Pittsburgh, October 29 and 30, under the presidency of Dr. William L. Dayton, Lincoln, Neb.

National Housing Conference.—The sixth National Conference on Housing in America was held in Chicago, October 15 to 17, under the auspices of the National Housing Association, in cooperation with the city of Chicago, and the Chicago Civic and Social Service Organization. Among the chief topics for discussion were, "Chicago's Housing Problem," "Industrial Housing," and a symposium on housing famines.

Bequests and Donations.—The following bequests and donations have recently been announced:

Dr. John B. Briggs, Hartford, Conn., one-half the estate of Mrs. James E. Nichols, amounting to nearly half a million dollars.

To establish the Dr. James M. Ferguson Home for worthy poor and homeless white persons of El Paso County, Colo., the estate of Dr. James M. Ferguson, valued at about $20,000.

George F. Geisinger, Memorial Hospital, Danville, Pa., an endowment of $1,000,000, by Mrs. Abigale E. Geisinger.

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the Alvarenga Prize for 1917 has been awarded to Dr. Wilbur C. Davison, Baltimore, for his essay entitled "The Superiority of Inoculations with Mixed Triple Vaccine (*B. typhosus*, *B. paratyphosus* A and *B. paratyphosus* B). Over Successive Inoculations with the Single Vaccines, as Shown by Agglutinin Curves in Men and Rabbits." The next award of the prize, being the income for one year of the bequest of the late Señor Alvarenga, amounting to about $250, will be made, July 14, 1918, provided an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays for competition may be on any subject [illegible]ine, but cannot have been published. must [illegible]n, and if written in a language

English, should be accompanied by a translation. They must be received by the secretary, Dr. Francis C. Packard, 19 South Twenty-Second Street, Philadelphia, on or before May 1, 1918. Essays must not be signed, but must be marked with a motto, and accompanied by a sealed envelope having on the outside the motto, and inside the name and address of the author.

Meeting of Clinical Congress of Surgeons.—Special arrangements have been made for the evening sessions of the meeting of the Clinical Congress of Surgeons in Chicago, October 22 to 26. The programs of these sessions will be devoted especially to war subjects. As corrected to date of going to press, it is as follows:

MONDAY, OCTOBER 22, 8:15 P. M., ORCHESTRA HALL

Address by Chairman of Committee on Arrangements ....
.................................A. J. Ochsner, M.D., Chicago
Remarks of Retiring President ....Fred B. Lund, M.D., Boston
Inauguration of President-elect......John G. Clark, M.D., Philadelphia
The General Medical Board of the Council of National Defense
..............................Franklin H. Martin, M.D., Chicago
Presentation of, and remarks by:
  Hon. Josephus Daniels, Secretary of the Navy.
  Surgeon-General William C. Gorgas, U. S. A.
  Surgeon-General William C. Braisted, U. S. N.
  Surgeon-General Rupert Blue, U. S. P. H. S.
  Colonel T. H. Goodwin, Representative of the Director-General, British Army Medical Service.
  Colonel C. Dercle, Representative of Medical Department, French Army.
  Major Charles H. Mayo, M. R. C., President, American Medical Association.
Observations upon the Medical Service of the British Army
..............................Sir Berkeley Moynihan, Leeds, Eng.
The Work of the American Units in France,
..............................George W. Crile, M.D., Cleveland.

TUESDAY, OCTOBER 23, 8 P. M., GOLD ROOM, CONGRESS HOTEL

Symposium: Sanitation and Sepsis—
  The Work of the Army Surgeon..Surg.-Gen. Wm. C. Gorgas, U. S. A.
  The Work of the Navy Surgeon..Surg.-Gen. Wm. C. Braisted, U. S. N.
  In the Training Camps..........Col. E. L. Munson, M. C., U. S. A.
  Military Laboratories .... Col. F. F. Russell, M. C., U. S. A.
Symposium: Antiseptics—Edward Martin, M.D., Philadelphia; H. D. Dakin, M.D., New York; E. H. Dunham, M. D., Philadelphia; Alexis Carrel, M.D., New York; Wm. O'Neill Sherman, M.D., Pittsburgh; W. Estell Lee, M.D., Philadelphia.
Extra Cantonment Zones ....Raymond D. Fosdick, New York
The Control of Venereal Diseases..Wm. F. Snow, M.D., Washington

WEDNESDAY, OCTOBER 24, 8 P. M., GOLD ROOM, CONGRESS HOTEL

Symposium: Military Surgery and the Specialties—
  General Surgery.........Maj. Charles H. Mayo, M. R. C., Rochester
  Reconstruction Surgery ....Maj. Edgar King, M. C., U. S. A.
  Head Surgery.............Maj. Walter R. Parker, M. R. C., Detroit
  Brain Surgery ....Capt. Charles Bagley, Jr., M. R. C., Baltimore
  Ophthalmic Surgery.....Maj. James Bordley, Jr., M. R. C., Baltimore
  Surgery of the Ear, Nose and Throat
  ....C. W. Richardson, M.D., Washington
  Oral Surgery .... Maj. Vilray P. Blair, M. R. C., St. Louis
  Orthopedic Surgery ....Maj. E. G. Brackett, M. R. C., Boston

THURSDAY, OCTOBER 25, 8 P. M., GOLD ROOM, CONGRESS HOTEL

Presidential Address: The Use of Radium in Gynecology
..............................John G. Clark, M.D., Philadelphia
Surgery of the Spinal Cord......Charles H. Frazier, M.D., Philadelphia
  Discussion by Allen B. Kanavel, M.D., Chicago.
Surgery of the Stomach......William J. Mayo, M.D., Rochester, Minn.
  Discussion by A. J. Ochsner, M.D., and L. L. McArthur, M.D., Chicago.

FOREIGN

Red Cross Mission in Italy.—The *Policlinico* states that a mission from the American Red Cross is in Rome to study conditions on the Italian front, in the hospitals, etc. They were received and welcomed by Senator Comte Della Somaglia, president of the Italian Red Cross, the prefect of Rome, and other notables.

New Piñero Hospital at Buenos Aires.—The hospital provided for by the bequest of P. Piñero in 1907 has just been opened. There are to be five pavilions, with a capacity of 625 beds. The bequest stipulated that the hospital must be opened to the public before Sept. 12, 1917, but the war has interfered with obtaining materials from Europe and elsewhere, so that only the outpatient department and emergency station as yet are open to the public. Dr. R. Spurr is the chief medical director of the hospital. It is to be in charge of the Asistencia Publica of Buenos Aires, the central organization of all institutions devoted to the care of the sick poor.

Deaths in the Profession Abroad.—**F. W. Kidd**, professor of obstetrics at the University of Dublin, at one time president of the Irish Medical Association and member of the council of the British Gynecological Society.——**R. Oeri**, Basel, aged 68.——**M. F. Escudero**, prominent surgeon of Buenos Aires, aged 43.——**B. Hernandez**, Madrid, in charge of the antirabies service there.——**A. Jouty**, who succumbed to fulminating septicemia from an accidental infection incurred in his war service of otorhinolaryngology at Lyons. From recent casualty lists, British: **Lieut.-Col. E. H. Openshaw**, presumably in Mesopotamia; **Capt. B. A. Bull, Lieut. D. Anderson, Capt. W. J. Evans, Surgeon H. A. Potter, Col. T. Daly**, assistant director of the medical services, lost in sinking of transport *Arcadian;* **Capt. J. W. S. Wilson, Fleet Surgeon E. C. Ward, Capt. A. S. Taylor, Capt. R. W. Shegog, Captain Neligan, Lieut. A. G. Dunn, Capt. B. Woodhouse, Capt. N. G. Chavasse**, awarded the Victoria Cross. In Italy: **Lieut. F. Pittaluga, Capt. C. Zucchetti, Lieut. A. Buonomo, Lieut.-Col. D. Sonnino, Lieut. E. de G. di Santa Severina.** In France: **Aide-Major P. Reynaud, A. J. Giordani, Lieutenant Duguit, Captain Morin**, chief of the hospital at Vadelaincourt, shelled by aeroplanes, one bomb killing him and the soldier on whom he was operating.

PARIS LETTER

Paris, Sept. 6, 1917.

The Visit of the Uruguay Physicians

A party of medical men from Uruguay are touring the southwestern part of France at present. They started in the Arcachon region, investigating its climatotherapeutic resources. The party was entertained by the Arcachon Medical Society which took them to visit the summer and winter resorts and the headquarters of the society, its collections and its laboratory.

Physicians Victims of Their Devotion

The death of Dr. Leon Bonnet, aged 58, has been reported from Puy-en-Velay. He was one of the first medical men to study the roentgen rays, and he has just paid with his life for his devotion to science and his patients. He contracted the disease to which he succumbed while working with the roentgen rays.

Radiologic science has also to record another victim, Dr. Vaillant, chief of the service of radiology at the Lariboisière hospital. He has just had to have his left forearm amputated because it had become gangrenous under the use of the roentgen rays. During the twenty years that he has been working with these rays he has had a number of accidents. First, several years ago, one and then two fingers of the left hand had to be amputated, and then one finger of the right hand. In spite of the precautions taken, the evil grew constantly worse and the forearm has had to be removed.

The American Red Cross Canteens for Soldiers

The war council of the American Red Cross has decided to expend $700,000 in the organization of canteens and lounging places for the use of French and American soldiers. They are to be close to the front and in the railway stations, and are to be equipped with writing materials, games, facilities for bathing and arrangements for the sale at cost price of small useful articles and comfort supplies.

Physicians and the Coal Card

I have already mentioned in a previous letter the institution of the coal card. The organized physicians of the Seine department, the Syndicat, has appealed to the highest local authorities, calling their attention to the situation as it affects physicians. Their communication says: "As the coal card is to be inaugurated, September 1, it is necessary that the situation as it affects the medical corps must be cleared up before that date. During the discussions preceding the inauguration of the coal card, it was heard that the liberal professions would be granted special privileges, as lawyers and physicians are obliged to have a room in which they receive their clients and a waiting room for them. It is estimated that these rooms would have to be heated on an average four hours a day, that is, omitting Sundays, 4 × 2 × 27 = 216 hours of heating per month, which would have to be added to the amount apportioned for each individual coal card. The medical corps of Paris, not being under the jurisdiction of the Chamber of Commerce, is compelled to apply to the highest local authority, the prefect of the department, to obtain that to which it is entitled. We are convinced, besides, that it is only necessary to call your attention to the needs of the profession to have them recognized and satisfaction granted."

The War

THE MEDICAL SERVICE IN THE ARMY IN MACEDONIA

M. Justin Godart, undersecretary of state for the military medical department, on his return from his recent visit to the eastern firing line, sent the following letter to the commander in chief of the medical forces of the armée d'Orient:

"On my visit to the medical and surgical quarters of the armée d'Orient I saw at the front and even in Saloniki the results of the work and devotion of all the personnel in your command. The difficulties to be overcome, depending on the question of transportation and climatic conditions, were of the most serious kind, and were further aggravated by the colonial character of this war. But thanks to the close collaboration between the military command and your department, it has been possible to effect day by day material improvement both from the practical and from the scientific standpoints.

"Please convey my congratulations and my thanks to every stretcher bearer, nurse (men and women), physician, pharmacist, and administrative official. Far from their native land, they have served their country well, devoting themselves entirely to solicitude and care for the soldiers for whom we can never do too much. The Republic may justly be proud of all of them as well as of those doing the actual fighting."

THE SHELL SHOCK CASES

The report on the mental confusion cases among the men on active service was prepared in collaboration by Drs. Juquelier, Capgras and Bonhomme, and in an important summary of the subject, impossible to do justice to here, they called attention in particular to the following questions: (1) from the point of view of the etiology, the existence of cases of a purely commotional or emotional origin, without the influence of infection or intoxication; (2) the greater gravity of the prognosis in the commotional cases and their complication by sequelae, and (3) the importance of the sequelae, which may include psychoses and secondary psychoneuroses, among which are dementia praecox, masked epilepsy, the syndrome of hyperemotionalism and recurring conditions of oneirism, that is, dreamlike hallucinations while awake, etc.

The discussion bore mainly on points of detail. Dr. Delmas insisted on certain peculiarities of the war confusional state: its equal frequency in the wounded and the nonwounded; the importance among other sequelae of early dementia and the syndrome of hyperemotionalism, and the constant existence of a period of latency at the beginning of the "commotional confusion." Dr. Marie warned against the too early return to duty of the men thus afflicted; Dr. Meige, against errors of diagnosis between confusion and aphasia. Dr. Laignel-Lavastine emphasized the fact that emotional and concussional confusion are produced by a physiologic mechanism, the emotion generating the confusional state through the intermediation of the secretory disturbances which it induces.

THE DISTURBANCE IN THE PUPIL REACTIONS AFTER SHELL SHOCK

At a recent session of the Académie de médecine, Dr. G. Guillain, agrégé professor at the Paris Faculté de médecine and hospital physician, and Dr. J. A. Barré called attention to the changes in the pupil reactions which they had noted in twenty-six cases of concussion from explosion of a large shell without external wound. Sometimes, at first, the pupils are abnormally dilated, and show no reaction to light or accommodation. Usually the mydriasis is of different degrees in the two eyes; sometimes on one side only, sometimes on both there is no response to light; sometimes there is an actual Argyll Robertson sign; in other cases there may be a paradoxical reaction to light. In some of the cases of shell shock the pupils may be merely unevenly dilated without modification of the motor reaction to light or to accommodation. These disturbances in the milder cases of shell shock do not cause much trouble. They are transient, as a rule, lasting from three to fifteen or twenty days and sometimes longer, but they gradually improve and finally disappear completely. They remarked that it is somewhat difficult to understand the pathogenesis of these pupil disturbances. In six of the men, they coexisted with xanthochromia in the cerebrospinal fluid and slight meningeal hemorrhage, but in the majority of cases there was complete absence of any sign of meningeal hemorrhage. When there is a slight meningeal hemorrhage, it might be assumed that the cerebrospinal fluid had been rendered toxic by the products of hemolysis, and that this toxic influence had been felt by the fibers of the nerve roots, either on the centripetal or on the centrifugal path of the reflex, or else the small bacillary clots might have injured the fibers by compression. It seems also as if in many cases there may have been some direct peripheral source for the pupil anomalies, either from actual concussion of the retina or from some local concussion of the ciliary muscle or nerves under the influence of the explosion of the shell. Whatever their pathogenesis, these pupil modifications should be made known. They are by no means exceptional and their causal relations with the concussion seem to be evident.

[The French term *concussion* is used, by some strange twist of the language, exclusively to mean "graft," especially extortion by a public official. Consequently it is never applied, as in English, to denote the condition resulting from a violent shock. They use the term *commotion*, and men suffering from shell shock are called *les commotionés*.

LONDON LETTER

London, Sept. 18, 1917.

The War

AMERICAN PHYSICIANS IN ENGLISH HOSPITALS

In consequence of the shortage of physicians in this country, the War Office is substituting American Army surgeons for civilian physicians that are employed for part time in military hospitals. There are several reasons for this. As stated in a previous letter to The Journal, the Central Medical War Committee has informed the government that no more physicians can be taken from civil practice. The release of part-time men from the military hospitals will help to ease the strain in civil practice and enable more men of military age to be called up. Moreover, it is held that part-time men, because of the exigencies of their private work, are not a good bargain for the state, and it is always preferable to employ full-time men. Finally, the urgent need of the present time is for orthopedic surgeons, and America is well able to supply these.

PARATYPHOID FEVER AMONG BRITISH PRISONERS OF WAR

A serious outbreak of paratyphoid has occurred among British officer prisoners of war in the hands of the Turks at Yozgad, in Turkey in Asia. The mortality among the rank and file of British and Indian prisoners captured in Kut has been very heavy, amounting almost to 70 per cent. of the men captured. Among the officer prisoners, the mortality has been slight, and the latter are being treated as well as the circumstances of their captors allow.

TETANUS IN MILITARY HOSPITALS

The War Office Committee for the Study of Tetanus has published an analysis, compiled by Sir David Bruce, of the cases of tetanus that have occurred in military hospitals which is important, as it shows the effects of treatment. During four successive periods analyzed, the rate of mortality has steadily gone down. In the first period the mortality was 57.7 per cent.; in the second, 49.2; in the third, 36.5. In the fourth period there is a series of 100 cases of which sixty-nine patients recovered, a mortality of 31 per cent. The ratio of cases of tetanus to the number of wounded soldiers treated in home military hospitals was, roughly, six times as high in September, 1914, as it was two months later; and it remained at or about the lower level until the end of 1916. This fall in ratio was undoubtedly due to a great extent to the introduction of prophylactic injections of antitetanic serum, which took place about the middle of October, 1914.

The cases in the last period show once again that the shorter the incubation period the greater the mortality rate, and vice versa. There were only twelve cases with a short incubation period (that is, up to ten days), and sixty cases with an incubation period of more than twenty-two days; the shortest incubation period was seven days, and the longest 190. Since the beginning of the war there has been a diminution in the number of cases with short incubation periods, and a corresponding increase in the number of cases with long incubation periods. This is a measure of the action of the prophylactic inoculation of antitoxin. Sir David Bruce points out that it is sometimes by no means easy to decide whether a case is one of localized or generalized tetanus. He defines general tetanus as that in which spasticity or rigidity occurs in muscles distant from the site of the wound, trismus being the most common initial symptom. In local tetanus the spasticity or rigidity is confined to the muscles in the neighborhood of the wound. He looks on local tetanus as a much modified variety of the original disease, or even as a new type due to the action of the prophylactic injection. In general tetanus the toxin molecules may be pictured as gaining entrance to the circulation and so reaching all parts of the nervous system. In the last

100 cases, sixty-one were general and twenty-eight local; in the remainder there was doubt. In the sixty-one cases of generalized disease there were twenty-one deaths, a mortality of 34.4 per cent. All the patients with localized tetanus recovered. Trismus was recorded in fifty-four of the generalized cases, opisthotonos in seventeen. With regard to operative interference, the tetanus committee advises that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should always be given; further, they consider it probably safer to abstain from surgical interference with the wound until the ordinary treatment for tetanus has been carried out, unless there are other and imperative reasons for immediate operation.

When the symptoms of the tetanus have subsided, and the tissues are flooded with antitoxin, then the wound can be opened up and searched for foreign bodies or hidden collections of pus and tetanus bacilli. The analysis of the cases furnishes no evidence either for or against the intrathecal route. In the first year of the war the figures seemed to show that this route was better than others.

ORTHOPEDIC HOSPITALS AND CURATIVE WORKSHOPS IN ENGLAND

Considerable attention is being directed in this country, as in France, to the development of military orthopedic hospitals and curative workshops, which are being established in various parts of the country. In London there is at Shepherd's Bush a military orthopedic hospital with 1,200 beds. Since this hospital was opened in March, 1916, 1,270 men have been discharged, of whom 390 were permanently unfit, 325 were returned to duty, 507 were sent to command depots, and 515 to employments. There are departments for electrotherapeutics, massage and hydrotherapeutics. Curative workshops are being completed which will provide places for over 200 men. The work done includes engineering, electrical work, metal grinding and polishing, felting, tailoring, fancy leather work, carpentering, photography, art iron work, oxyacetylene welding, French polishing, painting and sign writing, metal engraving, coopering, motorcar overhauling, surgical bootmaking and repairing, and splint making. In all of these a high degree of efficiency is attained by the men.

INDIGENOUS MALARIA IN ENGLAND

Indigenous malaria has not been known in England since the early part of last century, when it was prevalent in certain marshy districts and known as marsh fever or ague. However, since the war several cases have been reported, especially among troops. The return of large numbers of men who have contracted malaria in the eastern campaigns means the presence of persons whose blood contains malarial parasites, and as anopheline mosquitoes are also present, the possibility of contagion exists. A case was recently recorded in the *Lancet* of malaria due to the benign tertian parasite in a soldier, aged 20, who had never been outside the British Isles. He was well until he reached a depot to which men who had returned from Saloniki with malaria were drafted. Under the advice of Sir Ronald Ross, the War Office has taken measures to prevent such infection. Patients with malaria will be segregated in special depots and hospitals, and quinin continually administered to soldiers that are likely to remain carriers of malaria. Health officers have been supplied with a memorandum on the subject to be circulated among physicians in order that they may report any cases of fever shown or suspected to be due to malaria, and that inquiries may be made as to the possible source of infection.

Low Birth Rate in Ireland

The fifty-third annual report of the Registrar-General for Ireland, giving statistics for 1916, shows that 22,245 marriages were registered during the year, equivalent to a rate of 5.13 per thousand of the estimated population. This rate is 0.44 per thousand below the rate for 1915, and 0.11 under the average for the ten years 1906-1915. The births registered numbered 91,437, being 21.1 per thousand, which is 1.9 below the average for the ten years 1906-1916. There were 71,391 deaths, equivalent to 16.5 per thousand of the population estimated to the middle of the year. The death rate is 1.1 below that for 1915, and 0.5 below the average rate for the ten years 1906-1915. The number of deaths from all forms of tuberculous disease was 9,323, equivalent to 2.15 per thousand. With the exceptions of 1912, 1913 and 1914, the rate for 1916 was the lowest recorded. The rate for tuberculous diseases in England and Wales during the same period was 1.35.

Marriages

LIEUT. LAVERNE B. SPAKE, M. R. C., U. S. Army, Kansas City, Kan., to Miss Ella Haines Vanneman of El Paso, Texas, June 30.

LIEUT. FRANCIS VINCENT GOWEN, M. R. C., U. S. Army, to Miss Marguerite J. Horan, both of Philadelphia, October 6.

LIEUT. MICHAEL JOSEPH MCCARTHY, M. R. C., U. S. Army, to Miss Blanche Reilly, both of Pottsville, Pa., October 3.

LIEUT. PHILIP MCQUESTEN, M. R. C., U. S. Army, Boston, to Miss Elizabeth Swart of Concord, N. H., September 27.

WILLIAM M. O'SHEA, M.D., Webster, Mass., to Miss Blanche E. M. White of Worcester, Mass., September 25.

LIEUT. LEON SOLIS-COHEN, M. R. C., U. S. Army, to Miss Marion Mansbach, both of Philadelphia, September 30.

SAMUEL RAYMOND FAIRCHILD, M.D., Pennsgrove, N. J., to Miss Ruth Lanahan of Louisville, Ky., September 15.

GAYLORD MCE. ANDREWS, M.D., Stella, Neb., to Miss Elizabeth Bookwalter of Kansas City, Mo., October 2.

CHARLES DIMM DIETTERICH, M.D., Parkerford, Pa., to Miss Aneeda Hill of Collegeville, Pa., September 26.

HENRY ASLOP RILEY, M.D., to Miss Mary Chaplin Edgar, both of New York City, October 6.

GEORGE H. CRAFT, M.D., to Miss Flo J. Redfield, both of Pittsburgh, at Erie, Pa., October 1.

OTIS GUY BACON, M.D., to Miss Bonnie Caley, both of Davidson, Okla., September 21.

EDWIN J. OXFORD, M.D., to Miss Gladys Baker, both of Chambers, Neb., September 30.

MATT R. ROOT, M.D., to Miss Henrietta Ziegle, both of Denver, August 28.

Deaths

Moses Greeley Parker, M.D., Lowell, Mass.; Harvard Medical School, 1864; aged 74; a Fellow of the American Medical Association; consulting oculist to St. John's Hospital, Lowell; assistant surgeon, Second United States Cavalry, during the Civil War; once president of the Middlesex North District Medical Society, and of the Lowell Medical Journal Society; president-general of the National Society of the Sons of the American Revolution, in 1911 and 1912; died at his home, October 2.

Eli Leinbach Klopp, M.D., Philadelphia; Jefferson Medical College, 1889; aged 61; a Fellow of the American Medical Association, and a member of the American Academy of Ophthalmology and Oto-Laryngology; for many years assistant professor of otology in his alma mater; aural surgeon and chief of the nose and throat clinic of the Jefferson Hospital; for ten years a pharmacist; died at his home, Oak Lane, Philadelphia, September 29, from disease of the kidneys.

Allen DeVilbiss, M.D., Toledo, Ohio; Miami Medical College, 1868; aged 75; a Fellow of the American Medical Association; a member of the Mississippi Valley Medical Association, and American Academy of Ophthalmology and Oto-Laryngology, and a trustee of the Lucas County Academy of Medicine; president of the DeVilbiss Manufacturing Company; a veteran of the Civil War; died at his home, October 1, from cerebral hemorrhage.

Thomas P. Russell, M.D., Oshkosh, Wis.; Vermont Medical College, Woodstock, 1852; aged 90; a Fellow of the American Medical Association; said to have been the oldest practitioner of Wisconsin; assistant surgeon of the Second Wisconsin Volunteer Infantry, and later assistant surgeon of the First Wisconsin Volunteer Cavalry, during the Civil War; died at his home, October 5.

John Francis Wouters, M.D., New York City; College of Physicians and Surgeons of the City of New York, 1888; aged 65; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of New York; for several years a member of the attending orthopedic staff of the French Hospital; died at his home, September 30, from heart disease.

Benjamin Franklin Spangler, M.D., York, Pa.; Jefferson Medical College, 1868; aged 73; a member of the Medical Society of the State of Pennsylvania; one of the organizers and for many years a director of the Drovers and Mechanics' National Bank, York; a veteran of the Civil War; died at his home, September 29, from disease of the stomach.

Harold Havelock Kynett, M.D., Philadelphia; University of Pennsylvania, Philadelphia, 1886; aged 55; formerly a member of the Medical Society of the State of Pennsylvania; a gynecologist; for several years president of the Philadelphia Choral Society; who had been crippled for many years by reason of an accident; died at his home, October 1.

Brent L. Barker, M.D., Monticello, Ill.; Louisville (Ky.) Medical College, 1897; aged 46; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; once secretary of the Piatt County Medical Society; local surgeon of the Illinois Central Railroad; died at his home, September 29.

Lieut. John Henry Andres, Jr., M. R. C., U. S. Army, Duluth, Minn.; University of Pennsylvania, Philadelphia, 1911; on duty with a medical detachment of field artillery at El Paso, Texas; was found dead in his room at a hotel in El Paso, October 5; death being due to an incised wound of the throat.

Carl Oscar Bernhardi, M.D., Rock Island, Ill.; Rush Medical College, 1902; aged 37; a Fellow of the American Medical Association, and a well known surgeon of Rock Island; who had been suffering from heart disease for six months; died in the Presbyterian Hospital, Chicago, October 8, from lobar pneumonia.

Harlan Page Ustick, M.D., Boise, Idaho, Hahnemann Medical College, Philadelphia, 1883; aged 68; founder of the town of Ustick, Idaho, and for several years president of the Ustick Bank; died suddenly, September 26, from heart disease at the Cinnabar Mine, near Yellow Pine, on Fern Creek, Idaho.

John W. Hawkins, M.D., Glasgow, Mo.; Jefferson Medical College, 1861; aged 79; a member of the Missouri State Medical Association, and president of the Howard County Medical Association in 1915; died at his home, August 5, from malignant disease of the rectum.

Jessie B. Pierce Garwood, M.D., Princeton, Ill.; State University of Iowa, Iowa City, 1888; aged 59; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; died at her home, September 12, from diabetes.

Loran W. Jordan, M.D., Wabash, Ind.; Hahnemann Medical College, Chicago, 1883; College of Physicians and Surgeons, Chicago, 1884; aged 64; formerly a member of the Indiana State Medical Association; died at his home, October 2.

Thomas McCrary Hughes, M.D., Russellville, Ala.; Chattanooga (Tenn.) Medical College, 1900; aged 41; a member of the Medical Association of the State of Alabama; was shot and killed by a companion, October 4, while on a hunting trip.

Joseph A. Hansler, M.D., St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1908; aged 40; a member of the Missouri State Medical Association; who went to San Antonio recently on account of his health; died at that city, October 4.

Fred Vandegraff Turk, M.D., Stilesboro, Ga.; Atlanta (Ga.) Medical College, 1892; aged 48; formerly a member of the Medical Association of Georgia; died at his home, September 5.

Emma Mehlmann, M.D., Oakland, Calif.; University of California, San Francisco, 1917; aged 33; died at the home of her sister, in Oakland, September 31, from leukemia.

Henry A. Litzenberger, M.D., Walnutport, Pa.; Medico-Chirurgical College of Philadelphia, 1897; aged 44; died at his home, about September 23, from heart disease.

Harry Vernon Weaver, M.D., New Bedford, Mass.; Boston University, 1893; aged 47; a Fellow of the American Medical Association; died at his home, September 21, from peritonitis.

Nicholos Soteriades, M.D., Waterloo, Ill.; University of Munich, Bavaria, 1876; aged 70; died at his home, September 10, from myocarditis.

James Heacock, M.D., Parsons, Kan.; Homeopathic Medical College of Missouri, St. Louis, 1872; died at his home, about September 24.

Charles E. Whitham, M.D., Lawrence, Kan.; Eclectic Medical Institute, Cincinnati, 1859; aged 87; died at his home, September 25.

Turner Eugene Balsley, M.D., Reidsville, N. C.; New York University, New York City, 1879; died at his home, September 1.

R. M. Hargett, M.D., Versailles, Mo.; St. Louis Medical College, 1872; died at his home, September 23.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

ALCRESTA IPECAC

Report of the Council on Pharmacy and Chemistry

The Council has adopted the following report and authorized its publication.

W. A. Puckner, Secretary.

In 1915 Alcresta Ipecac Tablets (Eli Lilly and Co.) were admitted to New and Nonofficial Remedies as a preparation of ipecac that is insoluble in the stomach but soluble in the intestines. It was supposed that this property would permit the administration of ipecac without the accompanying nausea and vomiting, and that this would be of especial advantage when using the drug in amebic dysentery. The systemic effects, of course, would be those of ipecac.

More recently, the manufacturers of Alcresta Ipecac have been advising its use in conditions which were not contemplated by the Council when the preparation was accepted for New and Nonofficial Remedies. They now claim that ipecac alkaloids have been shown to be useful in the treatment of typhoid fever, flatulence, diarrhea and constipation and that Alcresta Ipecac has these properties. Such a statement is misleading. While it is true that at one time ipecac was used promiscuously against "flatulence, diarrhea and constipation" there never has been and is not now any scientific evidence of its efficiency in such conditions except, of course, in diarrhea of the amebic type. As to the alleged usefulness of ipecac in typhoid fever: This has not even the sanction of tradition and the claim certainly should not be accepted until there is strong evidence to support it.

The advertising matter on Alcresta Ipecac also contained statements to the effect that ipecac alkaloids have a demonstrated usefulness in pyorrhea. Such an unequivocal statement is unwarranted. In spite of the enthusiastic advocacy, in the past, of ipecac alkaloids as a specific in pyorrhea alveolaris the preponderance of scientific evidence indicates that ipecac is of questionable value in this condition. Neither is there any substantial evidence to warrant the claim that ipecac alkaloids, when absorbed through the intestines, are demonstrably useful in amebic infections of the tonsils.

The reputation of the best drugs, whether unofficial or official, is bound to suffer if extravagant claims for them are permitted to go unchallenged. The referee of the Council, therefore, believed it necessary to call the attention of the manufacturers of Alcresta Ipecac Tablets to the statements made for the product and suggested that they submit evidence to substantiate the claims. This the manufacturers have refused to do. Their attitude in the matter, as well as their attitude toward the Council's work is expressed in the following letter:

> "Responding to your letter of March 10th, we beg to suggest that literature covering the different matters at issue are readily available to your referee, and all statements emanating from us are made advisedly.
>
> "If you cannot satisfy yourselves that this preparation is a scientific product, ethically advertised, and a desirable advance in therapeutics, you can only delete it from your next issue of New and Nonofficial Remedies."

It is to be regretted that Eli Lilly and Co. refuse either to withdraw or modify their claims or to substantiate these claims by scientific evidence. The statements as they stand are exaggerated, misleading and harmful. As such they conflict with Rule 6 of the Council and necessitate the omission of Alcresta Ipecac from New and Nonofficial Remedies. The referee recommended the adoption and publication of this report.

HEPATICO TABLETS

Report of the Council on Pharmacy and Chemistry

The Council has adopted the following report and authorized its publication.

W. A. Puckner, Secretary.

"Hepatico Tablets" (David Laboratories, Inc., Brooklyn) are sold under such claims as:

> "Hepatico Tablets directly stimulates the liver cells, producing an increased flow of bile rich in cholates, a solvent of cholestrin [*Sic!*] and a biliary antiseptic for Hepatic Insufficiency, Intestinal Putrefaction, Habitual Constipation and Gall Stones."
>
> "Hepatico Tablets contain a combination of bile salts, pepsin, pancreatin, ext. nux vomica and cascara." [In a formula given in the same circular cascara is replaced by the nondescriptive term "*cascarin*"].
>
> "These tablets are now being extensively used, with most excellent results, in intestinal putrefaction, or autointoxication *conditions, as an* intestinal antiseptic."
>
> "The increased amount of bile, which contains an excess of cholates, flowing continuously through the intestines, prevents abnormal fermentative and putrefactive processes in the bowels."

Comparing the alleged composition of, and therapeutic claims for, "Hepatico Tablets" with those made for "Veracolate" (The Journal, April 24, 1915, p. 1440) many points of similarity are seen. Veracolate was claimed to contain sodium glycocholate and sodium taurocholate with cascara sagrada and phenolphthalein and the mixture was also offered in combination with pepsin and pancreatin. Hepatico Tablets are said to contain sodium glycocholate and sodium taurocholate, cascara sagrada, pepsin and pancreatin.

Both are said to stimulate bile activity and to be disinfectants of the intestinal tract. The general similarity of the claims made for these two preparations may be seen by a comparison of two sentences taken from the advertising matter:

"The action of Veracolate is to *bring* about a profuse flow of healthy bile which prevents bile stasis. As the flow of bile is stimulated so antiseptic action ensues, calculi softened and the concretion and mucous eliminated."	"Hepatico Tablets bring about the secretion of healthy bile, which prevents *bile-stasis as the flow of* bile is stimulated, so antiseptic action ensues, calculi softened, and concretions and mucous eliminated."

A comparison with the claim made for Taurocol (The Journal, April 24, 1915, p. 1441) shows a similar resemblance:

TAUROCOL CIRCULAR	HEPATICO CIRCULAR
". . . Directly stimulates the liver cells, producing an abundant flow of bile rich in cholates, solvent of cholesterin and a biliary antiseptic."	"Hepatico Tablets directly stimulates the liver cells, producing an increased flow of bile rich in cholates, a solvent of cholesterin and *a biliary antiseptic* . . ."

It thus appears that not only is the composition of Hepatico Tablets essentially similar to Veracolate and Taurocol, but its promoters adopt virtually the same therapeutic nonsense used to exploit these competing preparations. There is no evidence that any of the constituents of Hepatico Tablets, or the combination as a whole has any such therapeutic merit as would warrant the claims made.

The Council declared Hepatico Tablets in conflict with Rules 6, 8 and 10 (unwarranted therapeutic claims, objectionable name and irrational combination of substances).

SOME MISBRANDED NOSTRUMS*

Sherman's Compound Prickly Ash Bitters.—The Prickly Ash Bitters Co. of St. Louis, Mo., were the sole proprietors of "Dr. B. F. Sherman's Compound Prickly Ash Bitters," which the government declared misbranded. The product, which contained 20 per cent. alcohol, was recommended in wineglassful doses three times a day or less but was declared to be "not an intoxicating beverage!" The government chemists reported that in addition to the alcohol, buchu was indicated and emodin present, but alkaloids were absent. It was sold as an effective remedy for Bright's disease, dropsy, diabetes, inflammation of the bladder, gallstones, leukorrhea, irregular periods, incontinence, retention and suppression of urine, for malignant diseases of the kidney and for various other conditions equally serious. The claims were declared recklessly and wantonly false and fraudulent. The company pleaded guilty and was fined $10 and costs.—[*Notice of Judgment No. 4455.*]

"Thorn's Copaiba and Sarsaparilla" and "Tarrant's Cubebs and Copaiba."—The Tarrant Co., New York City, shipped in interstate commerce quantities of "Thorn's Compound Extract of Copaiba and Sarsparilla" and "Tarrant's Compound Extract of Cubebs and Copaiba" both of which were declared misbranded under the Food and Drugs Act. Federal chemists reported that the former was essentially a mixture of copaiba and sarsaparilla extract. It was sold as a certain remedy for gonorrhea and gleet and as a remedy for pyelitis, whites, incipient stricture, affections of the kidneys and gravel. These claims were declared false and fraudulent. "Tarrant's Compound Extract" according to the federal chemists consisted essentially of a mixture of copaiba and cubeb extract. It was sold under claims very similar to those made for the first-named preparation, claims which also were declared false and fraudulent. The company pleaded guilty and was fined $25.—[*Notice of Judgment No. 4473.*]

V. I. G.—The Van Vleet-Mansfield Drug Co. of Memphis, Tenn., marketed "V. I. G.," which contained morphin. The government chemists analyzed it and reported that it was "an aqueous solution of glycerin, morphin, berberin, hydrastin and salicylic acid." It was sold under the claim that it was a "cure" for gonorrhea, gleet and leukorrhea and would prevent contagion when used immediately after connection. These claims were naturally declared recklessly and wantonly false and fraudulent. The company pleaded guilty and was fined $25 and costs.—[*Notice of Judgment No. 4423.*]

Correspondence

"THE OBJECTIONS TO RAW EGGS IN THE DIET"

To the Editor:—Your editorial of Sept. 22, 1917, p. 1005, on this subject, calling favorable attention to Bateman's article on the raw egg in the *American Journal of the Medical Sciences,* June, 1917, needs a preliminary reply. Were it not for the stamp of authority of the Sheffield Physiological Laboratory and the consequent serious results that its publication has already caused and likely will further cause, Bateman's flimsy, illogical, unscientific array of semifacts would not be entitled to notice. His conclusion is based on the narrow view that because of the loss of 15 per cent. of available albumin (which is not lost in feeding boiled egg white) the physician should discard the use of the raw egg as "illogical and inadvisable," and that "no advantage accrues." He cites out of but twelve persons observed (?) only one, a child 3 years old, who had diarrhea during the three days that one-half raw white of egg was given daily. Its effect on dogs of vomiting and purging were not reproduced on human subjects by Bateman. Bateman has ignored our later physiologic concept that the uncooked egg must have, besides its caloric value, also a value due specifically to its organized structures for bone, nerve, tissue and blood making, for its pulmonary, digestive, excretory and reproductive systems, for its ductless and other glandular structures, its enzymes, proenzymes, activating and interactivating, constructive and defensive mechanism, and for many potential qualities that are destroyed in cooked eggs. Bateman, without discussing these inherent qualities, would have us throw them away for the sake of saving a probable loss of 15 per cent. Even if the loss were 90 per cent., the raw egg would still in critical cases be worth many times the mere nutritional loss. Also other proteins can be added, and in many ways we can (Bateman admits as much) prevent the loss; but we have nothing in nutrition that can supply the perfect pabulum of the raw egg for the sick who may be especially deficient in these vital selective elements. Lest repeated favorable comment on Bateman's views by medical journals, by public health writers and by the lay press in their desire to publish the latest apparently authentic knowledge might lay the foundation for irreparable harm, I give this early warning until a more complete refutation of Bateman's position which I hope soon will be ready for publication. Nathan Rosewater, M.D., Cleveland.

---

* This material, with much additional, appears in the new edition of the pamphlet "Convictions," price fifteen cents.

[Comment.—Our correspondent has not offered a refutation of the scientific observations on which Bateman's conclusions are based. He has not denied that egg white is digested less readily in the raw form than when it is heated to the "coddling" stage at 70 C. (158 F.); nor has he denied that the use of a large number of raw eggs may be attended with putrefactive changes in the bowel. So far as its gross nutritive properties are concerned, the egg can still supply them after it has been cooked. When our correspondent defends the *liberal* use of raw eggs—if that is what he intends to do—by reference to "vital selective elements" and a great diversity of "potential equalities" of undemonstrated potency, he appears to us to enter the domain of vague hypothesis which we are less able to follow than the alleged "flimsy semifacts" referred to in our editorial. What evidence there is for the existence, in the egg, of "organized structures for bone," etc., for "activating and interactivating constructive mechanisms," etc., we are unable to learn. It is true that enzymes are destroyed by heat; but the day for calling on the enzymes of raw food to sustain subtle virtues in them is passing. It is doubtless true that thousands of raw eggs have been fed without obvious untoward effects to patients; likewise dozens of quarts of raw chestnuts have been eaten without serious consequences. These observed facts by themselves do not constitute a brief for either of the raw foods mentioned.

That well known writers at the present time are by no means agreed with the attitude of our correspondent is further shown by the following quotation from the recent little manual "The Physiology of Food and Economy in Diet" by Dr. W. M. Bayliss, professor of general physiology in University College, London, a physiologist of international repute, who writes: "There are one or two erroneous impressions as to the value of some particular foods that need correction. The first of these is that raw eggs are more easily digested than cooked ones. The contrary has been shown by careful experiments to be the case. Of course, if the white is boiled hard, it must be finely divided by chewing, otherwise the gastric juice can only attack it slowly from the outside. Probably the best form is that of custard. The reason why raw egg-white is difficult of digestion is that it contains something, in small amount, which has a powerful retarding or inhibiting action on the digestive enzymes. This is destroyed by heat."—Ed.]

"LARREY, THE ORIGINATOR OF THE RAPID EVACUATION OF THE WOUNDED"

To the Editor:—Anent the interesting historical account of Larrey, the famous surgeon and patriot, by Dr. King of New Orleans, published in The Journal, September 29, and your editorial eulogizing the same surgeon, I would like to quote the following from "La Campagne de Russie, Mémoires du Général Comte de Ségur, Aide-de-Camp de Napoléon," an eye witness and participant in the ill-fated invasion of and retreat from Russia. "In the furious engagement at Borodine, 20,000 wounded were picked up and carried about two leagues to the rear to the great abbey of Kolotshoc." Then the historian continues:

> "Le chirurgien en chef Larrey venait de prendre des aides dans tous les régiments. Les ambulances avaient rejoint; mais tout fut insuffisant. Il s'est plaint depuis, dans une relation imprimée, qu'aucune troupe ne liu eut été laissée pour requérir les choses de première nécessité dans les villages environnants."

"The chief surgeon, Larrey, had just gone for assistants from the regiments. The ambulances had rejoined, but were entirely insufficient. It has since been complained, in a printed account, that no soldiers had been left him for securing necessary things from the surrounding villages."

Larrey was probably the busiest surgeon that history has ever witnessed.

H. P. Ashe, M.D., Pittsburgh.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

"TREATMENT OF ANTHRAX WITH NORMAL SERUM"

To the Editor:—Since the publication of the abstracts of R. Kraus' article on the treatment of human anthrax with normal inactivated beef serum intravenously, I have been looking for rapid corroboration of this apparently important work. In The Journal, Sept. 15, 1917, p. 949, appears the abstract of an article by Lignières which is anything but corroborative of the beef serum treatment. Your editorial comment ("The Treatment of Anthrax with Normal Serum," The Journal, Sept. 29, 1917, p. 1085) ignores this objection and speaks of the treatment as resting on indisputable evidence.

Will you please state if Lignières has retreated from his position, and if Kraus' statements have been corroborated by other workers?

J. Seilin, M.D., Chicago.

Answer.—We wish first to call the attention of our correspondent particularly to the fact that the beef serum used by Kraus was heated before injection, as stated in our editorial. Kraus' observations are based on definite experimental evidence, and his conclusions as to the clinical value of the treatment, in view of his high reputation as an investigator, seem worthy of all consideration. With regard to Lignières' criticisms, these seem to be founded largely on analogy and not on direct observational or experimental contradiction of Kraus' work. It is, of course, true that confirmation from other sources of the success obtained by Kraus in treatment of human anthrax with heated normal beef serum should be obtained before the method is generally advocated and introduced. We are not aware of any evidence that directly controverts or confirms Kraus' investigations.

INCOMPATIBILITY OF QUININ WITH ASPIRIN—SODIUM BICARBONATE AND ACETANILID

To the Editor:—1. Will you please tell me why capsules containing quinin and aspirin become soft? Do they develop a toxic composition?

2. What is the value of sodium bicarbonate in the compound acetanilid powder?

C. W. Head, M.D., Windsor, Mo.

Answer.—1. The conversion of quinin to the toxic substance quinotoxin by acids, with particular reference to acetylsalicylic acid (aspirin), was discussed in The Journal, Dec. 18, 1915, p. 2187.

2. Worth Hale has reported experiments which indicate that sodium bicarbonate lessens the toxicity of acetanilid both on the heart and on the intact animal (The Journal, Oct. 23, 1909, p. 1403). In view of his work he suggested that, to lessen its toxicity, 3 grains of sodium bicarbonate to 2 grains of acetanilid may be tried (The Journal, Sept. 2, 1911, p. 840).

BOOKS ON HEALTH OF WAR WORKERS

To the Editor:—Please inform me where I can obtain the following: Goldmark, "Fatigue and Efficiency"; Lee, "Fatigue"; Harvey Lectures, 1906-1907; Vernon, "Output in Relation to Hours of Work," British *Health of Munitions Workers Committee.* They are references mentioned in The Journal, Oct. 6, 1916, p. 1125.

Carl J. Gade, M.D., Bridgeport, Conn.

Answer.—These may be obtained from the publishers or through any bookseller.

Goldmark, Josephine: Fatigue and Efficiency, published by Russell Sage Foundation, 1 Madison Avenue, New York, $2.
Lee, F. S.: Fatigue, Harvey Lectures, 1906-1907, p. 172, J. B. Lippincott Company, Philadelphia, $2.50.
Vernon, H. M.: Output in Relation to Hours of Work, Memorandum 12, British Health of Munitions Workers Committee, 1916, Wyman & Sons, 29 Breams Building, Fetter Lane, E. C., London, 1½ d.

RANCH ACCOMMODATIONS FOR NERVOUS GIRL

To the Editor:—I wish to learn of a ranch in the Southwest where accommodation for a nervous girl, aged 11, and her mother could be found for the winter. The place should be one in which there would be an opportunity to live out of doors and ride.

M.D., New York.

Answer.—We submit this communication to our readers. Replies should be sent to The Journal office where they will be forwarded to the physician who asks the question. Those answering should give the price that would be charged for the service asked.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Little Rock, Nov. 13-14. Sec., Dr. T. J. Stout, Brinkley.

ARKANSAS: Eclectic: Little Rock, Nov. 13. Sec., Dr. C. E. Laws, 803½ Garrison Ave., Fort Smith.

CONNECTICUT: New Haven, Nov. 13-14. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven.

CONNECTICUT: Homeopathic: New Haven, Nov. 13. Sec., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

CONNECTICUT: Eclectic: New Haven, Nov. 13. Pres., Dr. J. W. Fyfe, Saugatuck.

FLORIDA: Jacksonville, Dec. 4-5. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

MAINE: Portland, Nov. 13-14. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

NEVADA: Carson City, Nov. 5. Sec., Dr. S. L. Lee, Carson City.

OHIO: Columbus, Dec. 4-6. Sec. Pro-tem., Dr. Herbert M. Platter, 185 E. State St., Columbus.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

TEXAS: Dallas, Nov. 20-22. Sec., Dr. M. F. Bettencourt, Mart.

WEST VIRGINIA: Clarksburg, Nov. 21-23. Chairman, Dr. S. L. Jepson, Capitol Bldg., Charleston.

Hawaii May Examination

Dr. R. W. Benz, chairman of the Board of Medical Examiners of Hawaii, reports that 3 candidates were licensed at the examination held at Honolulu, May 7-10, 1917. The following colleges were represented:

PASSED

College	Year Grad.	Total No. Licensed
University of California	(1916)	1
Sendai Special Medical School, Japan	(1908)	1
Osaka Prefectural College of Medicine, Japan	(1905)	1

Iowa June Examination

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Iowa City, June 7-9, 1917. The examination covered 8 subjects and included 100 question. An average of 75 per cent. with not less than 60 per cent. in certain subjects, was required to pass. Twenty-nine candidates were examined, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1917)	90
Northwestern University	(1916)	82, 95
Rush Medical College	(1915)	97
University of Illinois	(1916)	92
State University of Iowa College of Homeo. Medicine	(1917)	93
State University of Iowa College of Medicine	(1917)	86, 89, 90, 91, 91, 91, 91, 91, 91, 92, 92, 92, 93, 93, 94, 94, 94, 95, 96.
St. Louis University	(1917)	82
Eclectic Medical College	(1917)	92.5
University of Pennsylvania	(1917)	94
Lincoln Memorial University	(1915)	76

Minnesota June Examination

Dr. Thomas McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, practical and written examination held at Minneapolis, June 5-7, 1917. The examination covered 18 subjects and included 80 questions. An average of 75 per cent. was required to pass. Thirty-five candidates were examined, all of whom passed. Five candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Rush Medical College	(1917)	90, 91, 92, 92.
University of Illinois	(1917)	85
Harvard University	(1914)	96
University of Minnesota	(1917) 86, 91; (1918*)	80, 82, 83, 84, 84, 85, 85, 85, 86, 86, 87, 87, 87, 87, 87, 88, 88, 88, 89, 89, 89, 89, 90, 91, 92, 93.

THE MODERN MILK PROBLEM IN SANITATION, ECONOMICS AND AGRICULTURE. By J. Scott McNutt, Lecturer on Public Health Service in the Massachusetts Institute of Technology. Cloth. Price, $2. Pp. 258, with illustrations. New York: The Macmillan Company, 1917.

A large number of interesting facts on the milk supply problem are brought together in this book. The discussion of the economic and administrative side of the question is particularly complete, and the author seems to appreciate the complexity of the whole question. He states emphatically (page 158) that sanitary milk need not cost much more than insanitary milk, but he also recognizes that in justice to the milk producer some increase in price is necessary on purely economic grounds. He calls attention, however, to the difference in local conditions and to the desirability of cooperation on the part of the different interests concerned in milk production and distribution. We note that the retail price of milk in Boston, which is in a section of the country where milk production is not especially cheap, is 11 cents a quart. At the present writing, in Chicago the consumer is requested to pay 13 cents a quart. The layman might suppose that conditions for cheap milk production are more favorable in Boston than in Chicago. It cannot be said that Mr. McNutt has proposed any general solution for the milk problem, but he has gathered together a number of pertinent facts and has called attention to data and lines of argument often ignored in discussions of the question.

DIAGNOSIS FROM OCULAR SYMPTOMS. By Matthias Lanckton Foster, M.D., F.A.C.S., Ophthalmic Surgeon to the New Rochelle Hospital. Cloth. Price, $6. Pp. 490. New York: Rebman Company, 1917.

This book is written from an entirely new point of view. The subject matter is arranged in the usual way—cornea, iris, optic nerve, etc.—and the various diseases and conditions are treated seriatim; but only their symptoms, objective and subjective, and "as such," are considered. There is nothing on history, course, morbid anatomy, pathogenesis, complications, sequelae, prognosis or treatment, and therefore no real differential diagnosis, which must concern all these things. It is obviously no book for the beginner; it will mislead the general practitioner, and it is not encyclopedic enough on symptoms to be a final reference book. Yet the author frankly meets these criticisms in his preface. He does not pretend to write a textbook. He just treats of symptoms, and has thereby done us a definite service; for we cannot get away from symptoms: they are and should be with us morning, noon and night. We have our works on pathology alone, on treatment alone, medical and surgical; why not on symptoms alone? The author's style is easy and fluent, and one reads on and on with interest and profit, surprised and often a little disconcerted that so true a picture of things is called up by symptoms alone.

SLOVAK (SLAVISH) SELF-TAUGHT. By S. Morávek. Cloth. Price, $1. Pp. 126. Monessen, Pa.: The Author, 1917.

Slovak is the language spoken by the people of northern Hungary and Moravia. It is closely allied to all the Slavic languages, so that a smattering of Slovak helps the physician in dealing with Slavs in general. With a little further study he can deal with Polish, Croatian, Bohemian, Serbian and Russian patients. It is an advantage that the Slavic languages resemble each other more as spoken than as written. "Slovak Self-Taught" is not a pocket manual, but has a stout cover about 9 by 6 inches. It contains thirty-six pages of classified phrases in common use, with the pronunciation, a vocabulary of thirty pages, and fifty-four pages of grammar. The print is unusually large and clear. A page and a half are devoted to "With the Doctor." This section is fairly complete, but it does not contain the terms of command: "Sleep" and "Wake up," which may be needed in case hypnotic suggestion is being used. The author has supplied these additionally, on request, as follows:

Sleep	Spi	(spi)
Wake up	Prebud sa	(prebudY sa)

Valid Provisions for Dealing with Tuberculosis

(Sacramento County vs. Chambers (Calif.), 164 Pac. R. 613)

The District Court of Appeal of California, Third District holds valid the act of 1915 which provides for the establishment and maintenance of a bureau of tuberculosis under the direction of the state board of health, defining its powers and duties, and provides for the granting of state aid to cities, counties, cities and counties, and groups of counties for the support and care of persons afflicted with tuberculosis. The court says that the fundamental proposition on which the argument against the constitutional propriety of the provision of the act authorizing the payment of certain sums to the counties was that the state has made it the duty of counties to maintain hospitals for the care, support and treatment of the indigent sick, and therefore the burden of supporting such hospitals is on the counties, and not on the state. There is no doubt the legislature intended to and did transfer from its own shoulders, and so placed on the counties, the duty and burden of caring for, supporting and treating the classes of persons mentioned. But this does not mean that the state has thus forever surrendered all control over those matters or the right itself to exercise full and complete and exclusive jurisdiction and control over hospitals for the indigent sick and helpless paupers. The constitution does not require this burden to be borne by the counties. The state may so transfer it to counties, however, in the exercise of its sovereignty. On the other hand, the state may take back and itself resume the exercise of certain functions which it has delegated to those local agencies; and, in some cases, particularly those having reference to the state's police power, the court knows of no reason, constitutional or otherwise, why the state and the counties may not act conjointly and synchronously in carrying out the policies of the former.

By health statistics and data gathered and published by the public health department of the state government, it has been shown that over one seventh of all the deaths in California, prior to the passage and enforcement of the law here under attack, were caused by this dread and justly dreaded disease, tuberculosis, and that, down to the time mentioned, the ratio of deaths from it was constantly increasing. Since then there has been a marked decrease in deaths from this cause. Still there are in the state large numbers of persons suffering from this deadly disease, mostly in the form of attacks on the pulmonary organs, very many of which persons are without financial means to pay for their own support and medical treatment, and without relatives legally liable or financially able to give them support and the care and treatment indispensable in such cases. The existence of such conditions is obviously a positive menace to the health of the inhabitants of the state.

The state undoubtedly has the right, under its police power, to adopt sanitary or other appropriate regulations, applicable to the whole state and to private as well as to public tuberculosis sanatoriums, looking to the stamping out of the disease and the prevention of its increase, and thus to the protection of the public health. With respect to county tuberculosis wards or hospitals, it proposes by the law in question to do no more than this. In authorizing the payment by the state of the sum named in the act to counties maintaining such wards or hospitals according to regulations formulated and promulgated by its health department, the legislature did not intend, nor was it the object of the act, to appropriate the state's money to or for the benefit of counties, but only to facilitate the proper execution of its scheme to control in part or itself supervise the matter of the treatment of indigent tuberculous patients, legally entitled to be taken care of at public expense. Obviously, the counties to which these moneys are authorized to be paid are, as to such money, mere trustees of an express trust, with absolutely no authority or right to divert the use of it to any other than the purpose or object for which it has been expressly appropriated by the state.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Thirtieth Annual Meeting, held at Newark, N. J., Sept. 17-19, 1017

(Continued from page 1294)

Acute Dilatation of the Uterus

DR. N. STONE SCOTT, Cleveland: A review of the literature gives the impression that acute dilatation of the uterus is of infrequent occurrence. A study of six cases has brought me to the conclusion that acute dilatation is not rare and has furnished an explanation of this apparent scarcity. Acute dilatation during the early months of pregnancy presents a marked difference from acute dilatation at term, in that it has no appreciable influence on the bleeding. The more or less complete hemostasis occurring after the complete separation of the placenta after an ordinary miscarriage depends on the hemostatic properties of the blood and the blood vessels, and this is not materially modified by an acute dilatation. A uterus at full term, which has been emptied of its contents, will cause an alarming hemorrhage if it does not contract and control the bleeding by muscular action. This is due to the changes which have taken place in the blood vessels during the pregnancy. Should a contracted uterus lose its muscular tone and again dilate, the same alarming hemorrhage will supervene. Some authors believe that acute dilatation is a phenomenon of sepsis. Maier thinks acute dilatation will occur only when there has been a prior disease of the muscle wall. My cases support the theory that the disease must be in the uterine cornua, where interference with the uterine innervation will be most marked. Three of my patients had a placental implantation in one or the other horn, and the fourth had a small fibroid in the same place. Great dilatation occurred only in those who had been recently pregnant.

DISCUSSION

DR. HUGO O. PANTZER, Indianapolis: A case occurred in my practice within the last seven weeks. The woman, aged 38, was operated on for appendicitis. She had had continuous bleeding for six weeks. She had been married many years, but was never before pregnant. The breast changes were indifferent; a diagnosis of pregnancy was doubtful. A fibroid tumor as a possibility was entertained. On dilating the uterus I found the phenomenon described by the essayist. For a moment I was in doubt as to whether or not I had perforated the uterus. I opened the abdomen from above and found the uterus relatively small and not perforated. I removed the fetus through an opening made in the uterus.

DR. EDWARD J. ILL, Newark, N. J.: I have heard of these cases, but I have never seen one. What I have seen, when we thought we had such a case, was that the curet or sound was passed through the posterior wall of the uterus into the peritoneal cavity below the os internum. I think that in Dr. Pantzer's case there was a perforation of the uterus low down behind or at either side. I have seen a crochet needle go into the cellular tissue behind the uterus.

DR. WILLIAM H. HUMISTON, Cleveland: A woman who had had several attacks of appendicitis aborted. I introduced a dull curet, and it went on in without any effort. I had perforated the uterus. I removed the placental tissue and opened the abdomen. There was a puncture in the posterior uterine wall. I removed the appendix, sewed up the hole in the uterus, cleaned out a few clots in the pelvis, and the woman recovered.

DR. JAMES E. DAVIS, Detroit: When a muscle is stimulated with the electric current, the muscle bellies out. If we continue the application of the electric current until extreme irritation is reached, the muscle will lengthen. According to Young, the epithelium of the chorionic villi, during the first three or four months of pregnancy, throws out an enzyme which has the effect of producing, first, edema, and later on marked dilatation of the blood vessels. This edema may be so marked as to extend throughout the entire body, a condition which has been regarded as an error in the kidney condition.

Dr. J. Henry Carstens, Detroit: As the result of profound anesthesia there is relaxation of the uterine muscles, a dilatation. The muscles become flabby, and when a sound is introduced into the uterus, provided the muscles have not undergone fatty degeneration, the uterus is shoved away up and it seems ballooned when it is not. The uterus is of normal size, but its walls are thin.

Dr. Van Amber Brown, Detroit: Was there in any of your cases a marked anemia that antedated the pregnancy?

Dr. N. Stone Scott, Cleveland: I would not say that none of them had anemia, but some of them did not have sufficient bleeding to produce anemia. Some of the patients were healthy young women who were not anemic.

Mixed Cell Tumor of the Kidney

Dr. William E. Darnall, Atlantic City, N. J.: These tumors are considered malignant, but may be benign. Whether they are to be classed with carcinomas or sarcomas seems to be a question pathologists have never definitely decided. Metastases occur late. The suprarenal tumor may arise from suprarenal rests in ectopic portions of kidney, ovary, testicle, liver, mesentery, lungs or bones. These tumors are always made up of mixed cells. The term "hypernephroma" has been applied to them, but hypernephroma may mean almost anything that is a kidney tumor. The immediate mortality from operation is high. Recurrences are said to take place in from 70 to 80 per cent. of the cases. Early diagnosis and operation are the only hope of saving more of these patients. A large percentage of them develop metastases and die. Some, however, have remained well after the removal of the tumor. More favorable results might be obtained if the patients could be discovered and operated on earlier.

DISCUSSION

Dr. E. Gustav Zinke, Cincinnati: I am reminded of a theory of the occurrence of cancer that has been more or less abandoned: that all cancers are really of embryonal origin. Some of these embryonal cells become shut off from the rest; they go to sleep, as it were; they remain inactive and inert for years, and sometimes, as the result of an accident, a fall or a blow, or in consequence of some irritation, they are reawakened, they become active, and the result is a malignant growth.

Dr. Gordon K. Dickinson, Jersey City, N. J.: Dr. Carstens brought out at the meeting of this association a year or two ago the fact that there may be many severe continued irritations without producing carcinoma. The theory of Cohnheim that cancer is of embryonal origin appeals very strongly to me.

The Left Fallopian Tube and Intestinal Stasis

Dr. Douglas H. Stewart, New York: A concealed gonococcus infection may set up a salpingitis and an ileus. In two patients whose fallopian tubes showed no change, except such as might be expected to occur from an excess of nutrition, a portion of such tubes adhered to the anterior wall of the rectum, formed a band there, obstructed the fecal flow, and at the same time derived a new and an additional source of blood supply. Such an obstruction may be differentiated from a Houston's valve because it is rigid and unyielding and because it is so plainly not within the lumen, but on the outside of the rectal wall. As a result of fatigue and muscular exhaustion due to the constant if partial resistance of the obstacle, the bowel balloons both above and below the band. The condition is not a rare one. Any surgeon coming across it during his exploration of an abdomen would simply term it a band, would cut it and relieve all the symptoms without troubling himself to determine the nature and origin of that band. Both my patients were well past the menopause, yet the new blood supply prevented atrophy of that portion of the tube that had become adherent. Removal of the hypertrophied section relieved all adverse symptoms by freeing the intestine and allowing it to resume its functions unhampered.

18. Radium Treatment of Carcinoma of Bladder and Prostate.—Two of twenty-five cases of carcinoma of the bladder treated by Barringer would, *he says, have been considered* good operative risks; the other twenty-three cases, because of the extent of the tumors, were all impossible operative risks. In four of the twenty-five cases (three confirmed microscopically as carcinoma) radium has locally removed the growth. One of these has been cystoscopically cured *for ten and one-half months, one for five months,* and one recently. One has what is probably a slight local recurrence, although pathologic examination of a piece removed does not confirm this view. From results in these four cases it appears that radium can do as much as surgery for cases of bladder carcinoma without subjecting the patient to the danger and discomfort of a major operation. From thirty cases of carcinoma of the prostate treated by radium since October, 1915, the following conclusions are drawn: Radium treatment has caused with surprising regularity the *reduction or disappearance* of carcinomatous nodules of the prostate, in both early and advanced cases. The reduction which occurs *in carcinomatous lobes is,* so far as has been observed, permanent. The symptoms in those cases in which the carcinoma had been reduced show striking improvement. The primary effect of the radium may be to increase the amount of residual urine (if there be any). The ultimate effect of the radium application on residual urine is *probably negative,* the amount neither increasing nor *decreasing.* No sloughs have resulted from the radium needles. Radium apparently has a selective action on carcinoma. In one case *in which* the prostate was removed because of urinary *retention,* a moderate dose of radium was given five months before the prostatectomy. The prostate had been considerably reduced in size following the radium treatment. At operation the prostate shelled out like a nonmalignant adenoma. Very large carcinomas with cachexia and loss of weight are beyond radium or any other treatment.

22. **Modification of Noguchi Test for Syphilis.**—In using the Noguchi system Howard has found it of great advantage to sensitize the corpuscles with amboceptor before adding them to tubes containing patient's serum, complement and antigen. He snips strips of amboceptor paper into short lengths, enough to give a certain excess of amboceptor for the tubes needed. If, for example, ten tubes requiring two units each of amboceptor are desired, paper estimated to contain twenty-four units is used. These small bits of paper are placed in a centrifuge tube with 5 or 6 c.c. of normal saline solution and agitated every few minutes for thirty minutes to dissolve out all the amboceptor. The tube is then centrifuged for a short time to clear the solution of particles of paper, and the amboceptor solution is poured off into another tube. To this is added the corpuscles to be used in the tests at hand. If ten tubes, as for above example, 1 c.c. of a 10 per cent. suspension of washed human corpuscles is added and mixed thoroughly with a pipet. The mixture of amboceptor and corpuscles is next incubated for one hour. At the same time the rack of tubes containing the other components of the test is placed in the incubator for the same length of time, to allow fixation of complement if syphilitic antibody be present. At the end of the hour, or in less time, it is noted that the corpuscles in the amboceptor corpuscle mixture have dropped to the bottom of the tube and a few revolutions of the centrifuge packs them so tightly that the tube can be inverted in pouring off the saline without loss of a corpuscle. These sensitized corpuscles do not behave like normal ones, but are heavier and will begin to settle in a few seconds after being uniformly emulsified in saline. After pouring off saline which contains excess of amboceptor, sufficient saline is added to make exactly as many cubic centimeters of corpuscle suspension as there are tubes. The corpuscles are now thoroughly emulsified with a pipet and 1 c.c. added to each tube. Hemolysis is noted almost immediately in negative tubes and those containing no antigen. The most obvious advantage in the above procedure is exact control of amboceptor. By using an excess every corpuscle is certain to be completely sensitized while the excess is discarded.

44 Experimental Atherosclerosis. I. Adler, New York.—p. 581.
45 *Prophylactic and Therapeutic Properties of Antitoxin for Bacillus Welchii. C. G. Bull, New York.—p. 603.

38. **Neutralization of Antipneumococcus Immune Bodies.**—In empyema fluids resulting from infection with pneumococci, there are present large amounts of soluble substances which have the property of neutralizing pneumococcus antibodies. Similar substances are found in the blood of infected rabbits. When immune serum is injected into infected rabbits the immune substances disappear very quickly, and therefore are prevented from activity in overcoming the infection. When immune serum is administered to patients severely infected with pneumococci, the immune bodies may also disappear very rapidly, and this disappearance is probably associated with the presence of such soluble substances in the blood. The serum only becomes effective when these substances are neutralized. The study of agglutination curves is of value in showing why in certain instances favorable results have not followed the use of immune serum. Cole says that it is important that in severely infected patients the serum be administered early in the disease and that the initial dosage be large.

39. **Elaboration of Specific Soluble Substance by Pneumococcus.**—A specifically reacting substance of bacterial origin is present in the cell-free fluids of young cultures of pneumococcus. This substance is present when the organisms are growing at their maximum rate and undergoing little or no cell death, and consequently its presence is not dependent on cell disintegration but represents the extrusion of bacterial substance by the living organism. The blood and urine of rabbits experimentally infected with pneumococcus contain a similar specific soluble substance during the early hours of the infectious process. Human beings suffering from lobar pneumonia have in their blood, and more frequently in their urine, a specific soluble substance of pneumococcus origin. The amount of this substance present in the urine varies in different individuals, and the presence of a large amount is of unfavorable prognostic import. This specific precipitin reaction in the urine is of diagnostic value. Rabbits injected with soluble pneumococcus material continue to excrete this substance for a considerable period of time. The specifically soluble substance obtained from bacterial cultures and from the urine during infection is not destroyed by boiling, by precipitation with alcohol, acetone, or ether, or by trypsin digestion.

40. **Acidosis and Acid Excretion in Pneumonia.**—There is excreted in the urine of persons ill with acute lobar pneumonia a large amount of organic acid which is free at a hydrogen ion concentration of 5.0. Acidosis as determined by the combined carbon dioxid in the plasma, Palmer says, is seldom, if ever, severe.

41. **Epidemiology of Lobar Pneumonia.**—According to Stillman, pneumonia of Type I and Type II are responsible for the majority of the cases of lobar pneumonia. Among the pneumococci found in the mouths of healthy individuals Type IV predominates, Type III is frequent, and atypical organisms of Type II are occasionally found. Healthy persons intimately associated with cases of lobar pneumonia

may harbor in their mouth secretions the highly parasitic pneumococcus of Types I and II. Occasionally a carrier of Type I or Type II pneumococcus is encountered in whom it is impossible to trace any contact with an infected patient. From the dust of homes where cases of pneumonia due to Types I and II have occurred, pneumococci of the same type may be recovered.

42. **Production of Antipneumococcic Serum.**—In the production of immune serum for therapeutic purposes Cole and Moore say that strict attention must be paid to the immunologic specificity of the bacteria used for immunization. At present the only serum of which the therapeutic value has been proved is that effective against Type I pneumococcus infection. This serum should have agglutinating power for Type I pneumococcus and should have the power of protecting mice against large amounts of virulent culture. Experiments have shown that for producing the primary immunity most rapidly several series of small doses of dead cultures should be given, the injections being made daily for six to seven days, followed by a week in which no injections are made. To produce the highest type of immunity, probably, living organisms are required. These should be given in moderate doses daily for three days, with an interval of a week between each series of injections. By following accurately the methods described, horses may be made to produce rapidly a high grade of specific serum. The observations so far made indicate the importance of employing small doses of culture frequently repeated in this form of immunization.

43. **Antiblastic Immunity.**—Antipneumococcus serum under certain conditions apparently inhibits or retards the metabolic activities of the homologous pneumococcus. Antipneumococcus serum exhausted of its agglutinin content possesses no inhibitory properties. The degree of inhibitory action of antipneumococcus serum parallels its agglutinating power. No evidence has been found to indicate that the inhibition of the metabolic activities of the pneumococcus by antipneumococcus serum is due to a specific anti-enzymotic property of the serum. The evidence which has been obtained indicates that the apparent inhibition of metabolic activity that occurs under certain conditions is due to agglutination of the pneumococci by the antipneumococcus serum and their consequent inability to grow in intimate contact with the whole medium. Antistaphylococcus serum inhibits the liquefaction of gelatin and the formation of a pigment by *Staphylococcus pyogenes-aureus*. Further experimentation is necessary to determine the mechanism of this inhibitory action. Antistaphylococcus serum does not inhibit those metabolic activities of *Staphylococcus pyogenes-aureus* essential to the growth and multiplication of the organisms.

45. **Antitoxin for Bacillus Welchii.**—Bull has been able to confer on guinea-pigs a passive immunity of about two weeks' duration to *B. welchii* toxin through a protective administration of the antitoxin. Guinea-pigs which had received a prophylactic dose of *B. welchii* antitoxin exhibited pronounced resistance to infection with the virulent bacill for a period of twelve days. Established infections in guinea-pigs with *B. welchii* have been arrested and controlled by treatment with the antitoxin. Bull expresses the opinion that it will be possible to prevent *B. welchii* infection in man through the prophylactic use of the antitoxin, and developed cases of the infection may be controlled by therapeutic injections of the same agent.

Journal of Infectious Diseases, Chicago

York.—p. 409.

47. **Coccobacillus Ozenae of Perez.**—The characteristics of the bacillus of Perez are summarized by Ward as follows: It is gram-negative, grows well in mixed broth cultures, causes a slow fermentation of glucose, decomposes proteins with the formation of mercaptan, produces a characteristic pigment in gelatin, and evokes specific agglutinins in rabbits. These characteristics are adequate to distinguish it from other bacilli, with which it may be associated, such as *B. pyocyaneus*, *B. coli*, *B. mucosus*, *B. proteus*, and *B. bronchisepticus*. The bacillus is readily cultivated from the exudate in ozena, with which condition it is closely associated.

48. **Yeast-Like Fungi of Human Intestinal Tract.**—Anderson says that yeast-like fungi are commonly found in the intestinal tract of man. They are of many species and, for the most part, such types as are commonly present in nature and known as "wild yeasts." It is probable that these yeasts are ingested with the food. The feces of persons suffering from gastro-intestinal disorders of various types do not yield a larger number of yeasts than those from healthy persons. There is no one species commonly present in the intestinal tract of either healthy persons or those suffering from gastro-intestinal troubles.

49. **Stable Pollen Antigen.**—Aqueous pollen extracts are unstable and rapidly deteriorate, losing their potency after about three weeks. Clock has prepared stable pollen antigens which he has subjected to rigid tests for stability. A mixture was made of equal parts by weight of the pollens of timothy, red top, June grass, orchard grass, rye, sorrel, dock, daisy, maize, ragweed, and goldenrod—these being the pollens which are known to cause the greatest number of cases of the vernal and the autumnal type of hay-fever. Pollen extracted in 9 per cent. salt solution gave an antigen that deteriorated quite rapidly. Pollen extracted in 66⅔ per cent. glycerol and 33⅓ per cent. saturated sodium chlorid solution gave an antigen that has proved to be remarkable, stable and potent and which remains sterile.

51. **Preservation of Antisheep Hemolytic Amboceptor.**—Fresh antisheep hemolytic amboceptors that were heated to 55 C. for one-half hour, and then mixed with an equal volume of glycerol did not deteriorate, but retained their original titer for three years. During that period anticomplementary properties did not develop. The glycerol in the glycerolated antisheep hemolytic amboceptor did not influence the complement fixation reaction. Fresh antisheep hemolytic amboceptors that were inactivated and then preserved in glycerol, as herein described, were not only remarkably stable but were also protected from bacterial growth for a period of three years.

52. **Pneumococci and Streptococci.**—For the differentiation of the organisms of the pneumococcus-streptococcus group for clinical diagnostic purposes, a morphologic and cultural method which has yielded good results is presented by Aschner. Based on a study of many organisms according to this method, a classification has been adopted which seems to be as definite as can be attained in the present state of knowledge. There is much evidence that the classification is artificial from a biologic point of view, as shown by the variations within the classes, and by the existence of intermediate and transitional forms, as well as by the mutations described. The following mutations have been observed: (1) encapsulated hemolytic streptococcus converted into a pneumococcus; (2) encapsulated anhemolytic streptococcus converted into a pneumococcus; (3) pneumococcus changed into anhemolytic streptococcus; (4) anhemolytic streptococcus converted into a hemolytic streptococcus; (5) *Streptococcus mucosus* changed into an anhemolytic streptococcus.

104. **Carbuncle of Upper Lip.**—In considering the treatment of carbuncle of the upper lip Bradburn urges early incision with injection of 5 per cent. phenol solution into the infiltrated tissue. He cites four cases with 50 per cent. mortality.

107. **Moving Pictures and Eyes.**—Bahn believes that moving pictures under favorable conditions do not cause as much fatigue as the same period of concentrated reading. Under unfavorable conditions, moving pictures cause increased fatigue which, if continued, produces symptoms that are unpleasant and may be harmful. Most persons who complain that moving pictures cause ocular discomfort have some ocular defect. A review of the literature to date records no permanent harm to the eyes from moving pictures.

108. **Treatment of Pellagra.**—Cases of five patients are reported by Herold treated by his original method, normal horse serum administered intravenously. He claims for this treatment only that it does in a few days what proper feeding takes weeks to do, and that it will tide over and markedly improve that very troublesome class of patients whose mouths are in such condition that feeding is almost, if not quite, impossible.

116. **Drugs in Treatment of Heart Disease.**—The drugs which have been used in the symptomatic or palliative treatment of heart disease are legion, which proves their inefficiency. The majority are not worth naming, but a few of them have definite and even life-saving value. These few are discussed by Alsever. The digitalis group, consisting of digitalis, strophanthus, squills, apocynum, etc., stimulates directly all forms of muscle tissues, notably the heart and the vasomotors, and also the medullary centers, notably the pneumogastric and vasoconstrictor centers. As a result of these actions, the heart beats more powerfully and more slowly, the vasomotors contract and often diuresis ensues. These effects are of most importance clinically in auricular fibrillation and auricular flutter, and the results obtained in these disorders have been so marked and so valuable as to

give digitalis its justly great reputation in heart disease. Other types of irregular hearts and hearts with normal mechanism also respond to digitalis but in less degree. Tincture of strophanthus has sometimes been substituted for digitalis with advantage, but in the average case it is less dependable. Its action is practically the same as digitalis. Strophanthin, the active glucoside of strophanthus, is of inestimable value, because by giving $\frac{1}{100}$ grain intravenously one may develop digitalis effects in fifteen minutes. It is safer, however, to give $\frac{1}{250}$ grain and repeat every two hours for three doses, if needed. If a patient has been taking digitalis the administration of strophanthin intravenously is unsafe, because the combined effect may be overwhelming. Squills and apocynum are usually avoided because of their tendency to upset the digestive tract, but apocynum sometimes relieves cardiac dropsy when digitalis fails.

Strychnin should not be used in the belief or hope that it will stimulate the heart any more than other tissues. The caffein group is of considerable value in heart disease. Caffein, theobromin and theophyllin are the members of interest. Sodiosalicylate of theobromin is a powerful diuretic, and oftentimes of great value in cardiac dropsy. It increases the urine through direct stimulation of the kidneys rather than through action on the heart. In doses of from 10 to 15 grains, three or four times daily, it commonly produces marked diuresis in one or two days. When diuresis is established it is well to omit the drug, administering it again later in case of need. Theophyllin is more powerfully diuretic, but it is more nauseating and more expensive, so that theobromin is usually to be preferred. Caffein has been and still is used very largely as a heart stimulant or so-called tonic. Its effect is manifested almost entirely on the central nervous system, particularly on the brain itself. It has a little power to stimulate muscle fibers, but the heart responds no more than all the skeletal muscles. Alcohol is a local stimulant, but after absorption its action is purely depressing, affecting especially the central nervous system and beginning with the highest functions of the mind. Epinephrin is decomposed so quickly in the body that its effect must always be transient, and it is absorbed so slowly from hypodermatic injection that it is difficult to say just what action should be expected. Intravenous injections are followed by slower and stronger heart action and vasoconstriction, but when given by other methods these effects are very uncertain and fleeting.

The nitrites paralyze the vasoconstrictor mechanism and the vagus center, almost reversing the action of digitalis. Inhalations of amyl nitrite produce this effect in a few seconds, and the effect terminates in two or three minutes. Nitroglycerin and sodium nitrite by mouth produce this effect in two or three minutes, and the effect ends in one-half hour to three hours. Erythrol tetranitrate produces the same effect in one hour, and the action may continue for five hours. The nitrites are of great value in relieving the pain of angina pectoris and in obtaining relief from dangerous high blood pressure. It is usually unwise to attempt to beat down high blood pressure, except in an emergency. If a sustained depression of blood pressure is desired it may be obtained by repeating nitroglycerin every two hours or by giving erythrol tetranitrate four to six times a day. Aconite slows the heart by stimulating the vagus center but does not affect the vasomotors, consequently it lowers blood pressure. It may be useful in overacting hearts, as in fevers and in dangerous sustained high pressure.

117. **General Treatment of Heart Disease.**—Halsey emphasizes the importance of constant supervision, frequent rest periods or preventive convalescence and attention to the condition of the teeth and tonsils of children. He says that prevention of the occurrence of heart disease demands annual physical examinations of every individual.

118. **Hydrotherapy of Heart Disease.**—Schoonmaker summarizes his article as follows: First, hydrotherapy in heart disease is based on physiologic response to stimuli and is therefore scientific. Second, in hydrotherapy there are more possibilities for good in the treatment of heart disease than in any other single agent except rest. Third, the saline carbonated bath is especially helpful in the treatment of heart disease, because it makes possible the giving of cold tub baths without undue shock and provides a wide limitation in temperature, time and strength of bath. Fourth, as a therapeutic agent hydrotherapy is not incompatible with any other.

120. **Whooping Cough and Vaccination.**—More than 10,000 children have been vaccinated against whooping cough in Rochester. Less than 5 per cent. of the vaccinated children came down with the disease. They administer four doses four days apart, 500, 1,000 and 3,000 million. Two children exposed to whooping cough just after being vaccinated did not contract whooping cough until a year afterward. One of these patients had whooping cough in such a mild form that it was somewhat difficult to make a diagnosis; the other had whooping cough severely. In thirty-five patients who came down with the disease after whooping cough vaccinations, about half of them seem to have had the disease in modified form.

5 Rectal Diverticula as Causative Factor in Pelvic Inflammation in Women; Report of Two Cases. W. C. Swayne.—p. 91.

4. **Acute Pancreatitis.**—The first case reported by Morton is of special interest from the fact that, although when the abdomen was opened the presence of fat necrosis called attention to the condition of the pancreas, yet when the lesser sac of the peritoneum had been opened by division of the gastrocolic omentum, no definitely abnormal condition of the pancreas could be discovered, nor was the pancreas found to be diseased postmortem until it had been removed from the body, and then some lymph and hemorrhage was seen on its posterior aspect only; and on cutting into it some areas of slight hemorrhage and yellow infiltration were found. The morbid condition was almost confined to the middle of the organ, and although this was the part examined at the operation, none of these morbid changes could have been made out on inspection or palpation of the presenting aspect of the organ, for they were only discoverable on its posterior aspect. The second case is interesting and instructive from the fact that the vomit was fecal. The great interest of the third case was the apparent recovery of the patient after the acute stage. Serious symptoms, however, recurred and led to a fatal termination. The patient had so far recovered from the acute stage (which seemed probably due to the passage of gallstones or their retention in the common duct), that Morton discussed with the patient the desirability of having an operation for removal of gallstones before another attack came on, and yet at that time the acute pancreatitis must have been passing into the sloughing stage. In all three

of the cases there was a history of recurrent attacks of pain in the upper abdomen, not followed by jaundice. In one of the cases the gallbladder contained a large stone, and in another many small stones, and in the third no stones were found in it or in the common duct. It is unlikely that if the attacks in the third case, in which no stones were found in the gallbladder, had been due to the passage of gallstones, that every stone should have been passed before the onset of the fatal illness. Therefore, in this case at any rate, the recurrent attacks were probably not of the nature of gallstone colic, and it is doubtful if they were in the other two.

23 Unusual Form of Hypospadias. T. J. Thomas.—p. 425.
24 Biologic Aspects of Warfare. H. Campbell.—p. 433.

15. Tetanus Treated in Home Military Hospitals.—In the 100 cases of tetanus analyzed by Bruce the mortality was 31 per cent. The ratio of the number of cases of tetanus to the wounded has fallen greatly since the beginning of the war, due in all probability to a great extent to the introduction of prophylactic injections of antitetanic serum. The incubation period tends to become longer, hence there are only twelve cases reported with an incubation of ten days or under. Only ten patients are reported to have received secondary prophylactic injections of antitetanic serum in home hospitals. In regard to the therapeutic effect of antitoxic serum the evidence is still inconclusive. The rate of mortality in generalized tetanus is 34.4 per cent., in localized tetanus, 0.0 per cent.

17. Entameba Histolytica Carriers Treated with Emetin Bismuth Iodid.—The treatment of the 104 cases dealt with in this report was carried out in a special ward set apart for the purpose. The patients were under the care of one medical officer in order to keep the conditions of treatment as uniform as possible. The keratin-coated tabloids and, salol-coated pills were given in doses of 3 grains per day for twelve consecutive days without any additional treatment. The tabloids and pills were given entire as a full dose during breakfast. A patient was considered to be cured when at least six or seven negative tests were obtained over a period of not less than seven weeks from the termination of the course of treatment. It appeared (*a*) that carriers of *E. histolytica* who had not had any injections of emetin hydrochlorid were cured to the extent of 78 per cent. by two courses of the salol-coated emetin bismuth iodid pills. (*b*) In the case of men who had had emetin injections, 72.8 per cent. were cured by two courses of the salol-coated pills. (*c*) In the case of men who had not had emetin injections, 70 per cent. were cured by two courses of the keratin-coated tabloids. (*d*) In the case of men who had had emetin injections, 45.4 per cent. were cured by two courses of the keratin-coated tabloids.

For comparison with the above percentages of cures by a maximum of 72 grains of emetin bismuth iodid carried out in the special ward, Lillie and Shepheard give the number and percentage of cures in the other wards of this hospital. The number of grains of emetin bismuth iodid which these patients received varied from 36 to 200. A patient was regarded as cured after not less than five negative examinations over a period of not less than five weeks after the end of treatment. Out of 160 patients treated 142 were cured, namely, 88.7 per cent. There is no evidence that the length of time between the dates of onset of dysentery symptoms and the treatment has any effect on the chances of cure by emetin bismuth iodid. There is no ground for the belief that the vomiting diminishes the chance of cure by the emetin bismuth iodid treatment. There is nearly as much vomiting among the patients cured as among those cases in which there is relapse. The age of the patient has no effect on the chance of cure by the drug. But there is evidence to show that men over 40 years of age vomit less while undergoing treatment. The salol-coated pills are a distinct improvement on the keratin-coated tabloids from a curative point of view. They also cause less vomiting and loss of weight.

21. Roentgen Rays and Diseases of Bacterial Origin.—Kempster says that the effect of roentgen rays on diseases of bacterial origin is that they have not any germicidal powers, but that they have a decided inhibitory effect on the reproduction and increase of the germs, and that they produce stimulation of the living tissues leading to an increased phagocytosis, which is capable of destroying an unreproductive colony of micro-organisms.

33. Bronchopneumonia Following Pulmonary Hemorrage.—Among 1,000 odd cases admitted to the sanatorium of which Rheinhardt-Goodwin is resident medical officer in the last ten years, only one case of bronchopneumonia following hemoptysis has been recorded, while there have been many hundreds of cases of pulmonary hemorrhage. A woman, aged 27, was admitted, Sept. 30, 1916. There were signs of active disease in the right apex in front, and at the right base behind. The patient appeared to improve and was doing walks of 2 miles daily with satisfactory temperatures. Toward the end of January, 1917, however, there were a few small hemorrhages. Despite prolonged rest in bed there was further bleeding from the lungs. Many times her condition seemed incompatible with life, but each time she improved again. Between May 1 and 14 the patient seemed better, the color had improved, and she was able to take nourishment more freely. May 14, the temperature began to swing more during the twenty-four hours, cough returned, and there was much tenacious expectoration, which was expelled with difficulty. Sweating was profuse. The patient died quite suddenly on April 23. She became more cyanosed, later unconscious, and died with signs of asphyxia. At the commencement of the rise of temperature a hasty examination showed signs of consolidation over the back of the right lung, where there was bronchial breathing, and the same condition was present in the left apical region. Later in the course of the case the bronchial breathing over the right back gave place to loud tubular breathing and coarse crepitations, and these extended around to the base in front. Treatment throughout the case was symptomatic. The points of interest about the case seem to be: (1) the length of time, thirty-four days, the patient survived the onset of the bronchopneumonia; (2) the fact that morphin was not given to check the hemorrhage that apparently caused the complication, and could not, therefore, have been a factor. It was thought unwise to administer morphin on account of the violent vomiting caused on a previous occasion; (3) the three stages into which the course of the illness can be divided: (*a*) the first eleven days when the case conformed to the textbook description of a case of aspiration pneumonia, with continuous temperature, cyanosis, rapid respirations and pulse, absence of cough and sputum and no return of hemorrhage; (*b*) the next twelve days, during which the patient felt much better; (*c*) the last eleven days, when cough and sputum returned, sweating was profuse, the temperature became remittent in type, and the signs and symptoms suggested rapidly breaking down lung with cavity formation.

35. **Chronic Aspirinism.**—A woman, aged 50, suffering with typical rheumatoid arthritis, was in the habit of taking 10 grains of aspirin twice daily for seven years. During the first six years of the treatment the patient did not exhibit a single untoward sign of aspirin poisoning. There were no signs of gastro-intestinal irritation or of cardiac or mental depression. The first untoward sign of aspirin poisoning ensued in January, 1917, in the form of an intractable simple conjunctivitis, the patient complaining of "sand in the eyes." Examination showed a well marked hyperemia of both the palpebral and ocular conjunctiva; there was a slight degree of chemosis and considerable lacrimation. A week later the patient gradually became troubled with an urticaria which was not relieved by either dietetic or by the usual local or internal remedies. In a few days the patient was entirely covered by a typical urticaria major. The rash, which was present both day and night, assumed in parts the characters of an acute circumscribed edema, and elsewhere a severe urticaria bullosa. The symptoms rapidly became somewhat alarming, the patient was weak from insomnia, there were obvious signs of intestinal irritation in the form of diarrhea and vomiting, there was massive edema of the tongue and fauces, so that dysphagia became a marked symptom, and even an urgent tracheotomy was only averted by a prolonged administration of ice and ice water combined with astringent gargles. Vision was entirely obscured by an extreme palpebral edema. The urine gave an intense bluish violet reaction when tested with liquor ferri perchloridi, but the exact percentage of salicyluric acid was not estimated. A diagnosis of chronic aspirinism was made, and the drug rigidly withheld. Medicinal treatment consisted of 5 grains of ichthyol and a mixture containing liquor arsenicalis, tincture of belladona and calcium lactate, three times a day. Bromids were administered in large doses every night. At the end of the seventh week all trace of the urticaria had vanished and the urine was again normal. An interesting feature of the case is the fact that since the onset of the urticaria, although all aspirin had been discontinued, beyond the bony deformities all traces of the rheumatism have been entirely absent.

36 *Gunshot Wounds of Chest as Seen at Base Hospital in France. A. B. Soltau and J. B Alexander.—p. 259.
37 *Effect of Digitalis in Heart Disease with Pulsus Alternans. J. D. Windle.—p. 274.
38 Critical Review of Treatment of Syphilis. L. W. Harrison.—p. 29[illegible]
39 Purpura in Meningococcal Infections; Report of Cases. T. R. Elliott and H. W. Kaye.—p. 361.

36. **Gunshot Wounds of Chest.**—Among the 139 cases reported by Soltau and Alexander there were 80 cases of hemothorax, 13 of pneumothorax, 31 of collapse alone, 11 cases of nonpenetrating wounds with hemoptysis, 5 cases of penetration with no physical sign, 1 case of concussion pneumonia. Sepsis occurred in 13 cases as follows: following hemothorax (of which 4 were characterized by sudden gas formation, 10 cases; following pneumothorax, 2 cases; with gangrene of lung, 1 case. Mortality: total 10, or 7.1 per cent., as follows: from secondary peritonitis (probably pneumococcal), 1; from pneumothorax and associated tuberculosis, 2; from hemothorax and bronchopneumonia, 1; from gangrene of the lung, 1; from hemothorax and tetanus, 1; from hemothorax with pneumonia and pericarditis, 1; from pneumothorax (1 a few hours after arrival), 2; from pyohemothorax with subphrenic abscess, 1; contralateral collapse was noted in 24 cases.

37. **Effect of Digitalis in Heart Disease.**—Windle's experience of the clinical use of digitalis indicates that the drug has little, if any, power to bring about pulsus alternans in healthy or diseased conditions of the heart; and that in cases of heart disease in which this form of pulse is present there is no evidence that digitalis increases the irregularity; on the other hand, it frequently has the opposite effect, that is to say, the pulses become more equal in force and not uncommonly disparity in strength of the beats is temporarily abolished under the use of the drug, and the patients' symptoms for the time being are improved in all respects; moreover these good results not seldom ensue coincidently with a considerable rise in the blood pressure. Windle has given digitalis for various reasons to persons with healthy hearts, and out of a number of such cases in which the drug was pushed until its full physiologic effect on the stomach was produced, cardiac irregularity, namely, sinus arrhythmia and extrasystoles, ensued in several, but pulsus alternans occurred in one instance only. Windle suggests that it is probable that the beneficial effects of digitalis in heart disease with pulsus alternans are largely due to its action in restoring the tonicity of the heart and slowing its rate, although comparison of the tracings taken before and after the use of the drug suggest that it may exert an improving effect on the essential cause which gives rise to the pulsus alternans; that this supposition is improbable is evidenced by the fact that under certain circumstances the alternation is readily reinduced.

48 Urethra with Five Openings. Girard.—p 67.

43. **Wounds of the Bladder.**—Legueu has encountered 43 cases of gunshot wounds involving the bladder predominantly, and has been surprised at the immediate and remote mildness of the clinical picture therefrom. In some cases the bladder had been perforated or the projectile had passed entirely through it, and yet there were no serious symptoms from this at any time. In 6 cases of this kind, no operation and no special treatment was given. In 15 of the total 43 cases, an opening into the rectum or colon had been created by the projectile; in two cases the opening could be felt with the finger in the rectum. Even with these fistulas the evolution of the bladder wound was benign in 12 of the 15, the fistula healing spontaneously in the course of a few weeks or months. A vesicorectal fistula consequently does not call for operative

treatment as a matter of course. Before the projectile reached the bladder it had fractured the bone in 25 of the total 43 cases; the bone involved was the pubis in 17 cases, the sacrum, ilium and hip joint in 2 each. The fracture being compound and bathed in urine leads inevitably to infection unless the hole bored by the missile is given a prompt surgical clearing out, and the urine diverted by suprapubic cystostomy. In the 11 cases in which this was done at once, the wound healed smoothly, and in the 15 cases in which it was done at a later stage, it materially improved conditions. Even although this may not divert all the urine, it answers the purpose sufficiently. Otherwise there is liable to be a persisting fistula between the bladder and the site of the fracture after the skin wound has healed. Pus and sequesters from the suppurating process thus kept up in the bone, find their way into the bladder and start the production of calculi. Calculi may also develop from foreign bodies carried into the bladder with the projectiles. He found calculi in 10 of the 43 cases. In some the nucleus was a scrap of shell. Foreign bodies were removed from the bladder in 12 cases, including bullets in 3, scraps of shell in 5 and sequesters of bone in 4; this group does not include the foreign bodies removed at the first operation. He emphasizes that an extensive bladder wound from which urine escapes at once through the skin should be treated on the same principles as any other war wound, immediate clearing out of the passage made by the projectile, removing all foreign particles even down into the bladder, and sterilizing the whole passage.

44. **Emetin in Treatment of Bilharzia Hematuria.**—Diamantis discusses the clinical picture of bilharziosis with and without infectious complications, and reports striking results from emetin in treatment of noninfected cases. He administered the emetin intravenously, at two or three day intervals, commencing with 0.02 c.c. and increasing rapidly to 0.10, which dose he never surpassed. From fifteen to twenty injections generally answered the purpose. One patient was cured with eight, the largest dose 0.07. Vomiting and nausea are rare, but dizziness is constant, and there is always more or less pronounced asthenia, resembling the weakness liable to follow influenza. He expatiates on the mildness of bilharziosis, saying that the presence of the parasite in the veins does not cause any disturbance, only the passage of the eggs laid in enormous numbers, and passed off in the excreta. In the infected cases no benefit from the emetin was perceptible and the emetin asthenia tended to debilitate further.

44. **Bilharziosis.**—Morel discusses the wide distribution of the *Schistosomum hematobium*. All Africa, the eastern shore of the Mediterranean, the Asiatic shore of the Indian Ocean, and parts of Australia are known to be infested, and the war is bringing it to Europe. He describes four imported cases recently encountered at Paris. From his experience and review of the literature he concludes that there is no specific treatment; emetin and salvarsan seem ineffectual. The only local measure that has shown any efficacy is iodin vapor treatment, and even this acts only on the bladder itself, not killing the parasite or its eggs.

Diamantis and Lotsy report from Cairo a case in which the passage of a kidney stone apparently injured the ureter on its way, thus affording a predisposition so that casual infection with the bilharzia soon afterward caused the parasite to locate in the ureter. The resulting ureterovesical bilharziosis was revealed by radiography, the diagnosis confirmed by finding ova.

45. **The Objective Symptoms of Essential Incontinence of Urine.**—Noguès comments on the frequency of incontinence under the physical and emotional stress of the war. In civil practice the sphincters persist continent under ether or chloroform, but when given to the wounded within eight or ten hours of their wound, involuntary emission of stool and urine is frequent. He has found that with men inclined to incontinence, the Ambard uremic constant may show abnormal conditions. Utteau has noted further a higher proportion of waste contents in urine voided involuntarily. Microscopic examination of the urine may thus suggest an objective basis for the incontinence. This is evidenced further by changes in the contracting power of the vessel. A simple test for this is the injection of from 60 to 100 c.c. of tepid medicated water. With exaggerated contractility, the water is expelled abruptly and it is impossible to introduce more. Or the fluid may enter readily and not be expelled at all notwithstanding tenesmus. The response to these tests of the contractility cannot be controlled by the will. Cystoscopy often shows trabeculae in the bladder with incontinence, and the lumbar puncture fluid showed abnormally high pressure in eight of fifteen cases tested while the albumin content was abnormally high in 94 per cent., namely, above 0.10 gm. Even accepting 0.25 as the extreme physiologic limit, the albumin content was much above this in 27 per cent. This high albumin content may act on the predisposed nerves and thus bring on the incontinence. When one or more of these tests and signs are positive in a case of incontinence, the presumption is against simulation.

46. **Rupture of Hydrocele.**—Besides eight traumatic cases and seven cases of rupture from muscular effort, Ramos has collected a number of cases in which the rupture occurred without effort or traumatism. He reports a personal case in both the first and the last groups, and urges resection of the serosa as it is always more or less pathologic. Otherwise, after absorption of the effusion and obliteration of the perforation, the tumor rapidly returns.

49. **Progress in Otorhinolaryngology in 1917.**—Among the recent advances cited is mentioned the method of maintaining respiration and giving the anesthetic through a fine cannula introduced directly into the larynx by puncturing the cricothyroid membrane. Operations on the face and neck can be done then as tranquilly as if remote from the respiratory apparatus. Intratracheal intubation answers the same purpose but this requires more complicated instruments and irritates the vocal cords. Deafness is now classed as exempting from military service when loud speaking is heard only close to the ear. When loud speaking can be heard no farther than one meter, this compels acceptance only for the auxiliary military service; heard at four or five meters is the limit requirement for active service. Eleven different styles of tests for the hearing may be used. They include what is known as the cochleopalpebral reflex, that is, the involuntary winking when a sudden loud sound is heard close to the ear. This reveals simulation of deafness. The double tuning fork test is also instructive. Two tuning forks giving the same tone but with different intensity are placed at the same distance from each ear. With normal hearing the resulting unison is heard only on the side of the loudest tone. One tuning fork can be silenced to test the hearing. The simulator does not learn lip reading like the truly deaf. After a month of training he cannot read from the lips if a noise drowns what is being said. Another trick test is to tell the subject, speaking from some little distance, to raise his hand when he hears the spoken word. Then the examiner, speaking some syllable over and over again, walks toward the subject. The simulator raises his hand as the examiner comes quite close, thus showing that he had heard the command at a distance. Lip reading seems to be the only means of relief for the truly deaf.

55. Associated Paralysis of Last Four Cranial Nerves With and Without Sensory Symptoms.—Sicard and Rimbaud describe the clinical picture presented when a projectile has entered the region immediately below the anterior condylar foramen and the jugular foramen, inducing paralysis of the last four cranial nerves, and of these alone, with this exocranial type of injury. There is also an intracranial set of symptoms of the same type, but this can be induced only by an intracranial affection. In a typical case described, the trouble was of syphilitic origin and materially improved under specific treatment. In this case there were also sensory-motor disturbances in the limbs on that side. There was evidently some process involving the meninges and nerve roots in the left half of the cervicobulbar region. In the projectile cases, the paralysis involved the velum and larynx, the sternocleidomastoid and trapezium, the pharynx and heart nerves (evidenced by extreme tachycardia), and there was also atrophy of that side of the tongue. The young man had been shot with a revolver, the bullet entering back of the left mastoid region. At necropsy after pneumonia two years later the bullet was found in contact with the last four cranial nerves.

56. Mercurial Anuria.—The mercurial poisoning in the young man was manifested mainly by gastro-intestinal uremia, vomiting, diarrhea and Cheyne-Stokes dyspnea with a sensation of oppression in the chest, and anuria complete for two days and almost absolute during the three following days. While the anuria lasted, the young man complained of incessant chilliness, but there was no edema, headache, myosis nor gallop sound. During the polyuria reaction period, symptoms developed suggesting severe peritonitis except that the pulse was regular and slow and the temperature normal. Milian explains this as the result of the loss of fluids, the man having vomited more or less constantly for nine days, and the polyuria following the anuria having drained the body of too much fluid, causing a condition of dehydratation like that of cholera. Milian did not venture to make a saline infusion, fearing to bring on edema, but he gave an intravenous injection of a hypertonic glucose solution, 60 gm. of glucose in 200 c.c. of distilled water. The result, he says, was *réellement miraculeux.*

62 *Experimental Shell Shock. A. Mairet and G. Durante.—p. 478.

59. Single Mixed Vaccination Against Typhoid and Paratyphoid.—Widal and Salimbeni state that they have now a record of 12,000 men inoculated with a single dose of a vaccine consisting of equal numbers of typhoid, paratyphoid A and paratyphoid B bacilli. The dose was 1.5 c.c., containing six thousand million germs, heated, but without antiseptic. This method of vaccination has been in use for over a year, but sufficient time has not yet elapsed for the majority of the men for a decisive judgment as to its efficacy. They made a point of inoculating the men with this single dose, and repeating it in part of the men, hoping to establish thus the relative value of the single and double vaccination. For the present, they counsel the usual double method as being safer, but the outlook for the single, larger dose is growing brighter with every day that passes. It should certainly, they say, be given the preference when there is no time to give the usual two doses, and also in times when these diseases are epidemic. As vaccination is not compulsory for the civilian population, this single inoculation is often preferable for them as they do not take readily to this precautionary measure and often absolutely refuse a second inoculation.

60. Malaria in French Troops.—Ravaut and his co-workers at Marseilles comment on the peculiar persistency of malaria in the troops returning from Macedonia. They reiterate that the malaria parasite is the same old plasmodium and that quinin will kill it. The reasons for its inefficiency in these cases is because the men merely pretend to take the quinin given them. The hospital personnel are deceived and not until the urine was examined and no trace of quinin found in it, was the mystery of the peculiar tenacity of Macedonian malaria solved. They found one soldier who had an accumulation of 304 quinin tablets in his kit, and piles of quinin powders have been found in the mattresses in different hospitals. They describe the various tricks employed to avoid taking the quinin while deceiving the nurse to the effect that the drug is being taken regularly. Treatment of malaria thus assumes a psychologic aspect. A few drops of Tanret's reagent added to 2 c.c. of urine, voided in the presence of the physician, will turn the urine turbid and opalescent if it contains quinin. The reaction is stronger in proportion to the quinin content. The precipitate dissolves in alcohol and with heat, and reappears on cooling, while the albuminoid substances present are not modified and form a lumpy precipitate. This reaction persists positive for twenty-four hours with a dose of 0.5 gm. quinin, and for thirty-six and sometimes forty-eight hours with a dose over 1 gm.

The method of treatment best adapted to obviate deception was found to be the giving of the quinin in water at the two principal meals of the day, using a solution of 33 gm. quinin to the liter. The dose of 30 gm. of the solution corresponds to 1 gm. of the drug. Being taken with a meal and followed with an alkaline or acid drink, the drug is almost always borne without signs of intolerance. Ravaut makes a practice of alternating two days of the quinin with two days of arsenic treatment, and gives epinephrin in addition when there are signs of suprarenal insufficiency. [*Tanret's reagent is a mixture of mercuric chlorid, 1.35 gm.; potassium iodid, 3.32 gm.; acetic acid, 20 c.c. and distilled water to make 60 c.c.. It gives a white precipitate with albumin in urine.*]

61. The Blood Pressure Reveals Aortic Insufficiency.—Amblard analyzes the various factors which influence the blood pressure with aortic insufficiency, and declares that with a minimal pressure of 65 mm. mercury and maximal of 165 mm. we can be certain there is aortic insufficiency even when the lesion is not evident to the ear, and the pulse rate is normal. He estimates the normal range in health as from 80 to 140 mm. With aortitis and with kidney trouble the minimal pressure drops in the same way as with simple aortic insufficiency but it is only a relative drop, the differential pressure keeping about the same in all phases of aortic incompetency. This allows oversight of conditions as the case progresses, and, in connection with the pulse, estimation of the functional capacity of the heart.

62. Experimental Shell Shock.—Mairet and Durante reproduced with rabbits the violent shock from explosion of a large shell in the close vicinity without direct contact with particles of the shell. Five of the twelve animals died in the course of five minutes, one hour, or one to thirteen days. The others after a brief stunned condition, with acceleration of the respiration and transient agitation, rapidly recovered and were slaughtered later. Minute hemorrhages were found numerous in the lungs, spinal cord and nerve roots, and a number of small vessels in the gray substance of the cortex had ruptured into the sheaths of lymphatics. The smallness of these hemorrhages and the fact that they did not diffuse testify that they occurred instantaneously in consequence of the depression which followed the compression. These histologic hemorrhages entail anemia of the small territories beyond them, which explains the areas of softening to which Jumentié and Claude have called attention. These very numerous but very restricted lesions correspond to the symptomatology of men suffering from shell shock, especially the amnesia which may result from the anemia in certain small areas, the neuralgias, and the pains at the emerging points of the nerves. The latter correspond to the intraradicular hemorrhages found in the rabbits. This may also be the explanation of certain cases that have been published in which the clinical picture of tabes came on suddenly after shell shock, with negative Wassermann reaction and a rapid course. It may also explain the galloping course of general paralysis after concussion from an exploding large shell.

68 *Frothy Secretion in the Pyriform Sinus as Sign of Diverticulum in the Esophagus. E. Oppikofer.—p. 1133.

67. **Tuning-Fork Test for Disease of Nasal Sinus.**—Oppikofer states that he was unable to confirm Glas' statements in regard to the diagnostic importance of the Weber tuning-fork test applied in the diagnosis of disease in the nasal sinuses. He applied the test to sixty-nine adults with certain sinusitis, and obtained a positive response only in four, that is, in 5.8 per cent., and the response was not decided in these.

68. **Frothy Sputum in Pyriform Sinus as Sign of Esophagus Diverticulum.**—Oppikofer refers to Wagener's assertion in 1911 that the finding of frothy mucus in the fossa on the side of the larynx, external to the aryepiglottis fold, is presumptive evidence of a diverticulum in the esophagus, just below the pharynx. Von Eicken confirmed his statements in five cases, and Oppikofer reports the same finding in six cases of unmistakable hypopharynx diverticulum. The accumulation of frothy sputum at this point is therefore a simple and reliable sign which can scarcely fail to be present with a diverticulum in this region. At the same time, he warns, the frothy sputum in the hypopharynx may be encountered with any acute or chronic inflammatory affection of the esophagus, although it is not constantly found; also with laryngeal tuberculosis, cancer in the sinus, etc. He has further found the frothy sputum in the pyriform sinus in nineteen out of 200 healthy persons examined, that is, in nearly 10 per cent., but in these cases the sinus was not completely filled, and the frothy sputum was not found constantly in the same individual. It is therefore evident that pronounced frothiness in the hypopharynx is strongly suspicious of a diverticulum in the esophagus but it does not occur exclusively with this.

71. **Epidemic Meningitis.**—Indelli comments on the disturbances liable to follow excessive dosage in serotherapy of cerebrospinal meningitis. He reports the details of three typical cases to illustrate the advantages of giving small fractioned daily doses of the antiserum, testing the patient's tolerance for it, and supplementing this direct local treatment by giving the antiserum intravenously or subcutaneously. This mixed treatment seems more logical and has proved more successful in his experience. The patients whose cases are described were a child of 7 and two girls of 17 and 19. Two left the hospital quite cured; the third is still being treated for a residual paresis of one leg. In this case the intraspinal serotherapy had been supplemented by intraspinal injection of a silver salt. This was followed by extreme general prostration, rise of temperature and purpura, evidently from the toxic action of the silver salt. The patient was left in peace for a few days after this except for stimulants to the heart and morphin to relieve pains in the legs and headache. Then the symptoms seemed to be growing worse, but no fluid could be obtained with lumbar puncture. Intramuscular injection of the silver salt was followed by some improvement. The disease thus progressed in waves, gradually growing less pronounced, and the fortieth day the condition was no longer regarded as grave, and the patient is now well on the way to health. It seems evident that the intraspinal silver salt was a factor in the transformation of this "open" into a "closed" form of meningitis.

73. **Tuberculosis from the Military Standpoint.**—Maragliano remarks that there seems to be a good deal of uncertainty among the army medical officers as to tuberculosis in relation to the military service. He declares that the only question should be, Has the man any kind of a tuberculous affection? If the answer is affirmative, then there is only one thing to do, the man should be eliminated from the army. Even when the man is well nourished, he is liable to have his precarious balance upset at any moment. Hence he cannot be utilized in any way in military service which is liable to be or become eventually harmful for him. No gradations are possible, he insists. No physician can authorize the retention of a tuberculous man; no one can guarantee that he has sufficient resisting powers to bear the depressing influence of military life either in the active zone or back of the firing line. The state and military authorities demand that no person with tuberculosis detectable by the diagnostic measures at our command shall be admitted to the military service. A circular issued by the minister of war, April 15, 1917, deplores the fact that men have been passed for the service with tuberculous lesions so serious and advanced that ordinary clinical examination should have revealed them. Certain physicians in examining the recruits are misled by their zeal to swell the army ranks, and they pass candidates who, they think, are capable of rendering good service even although they know that the men are tuberculous. But the nation and the government do not want this at all. Physicians should follow the lines laid down for those who are responsible for the make-up of the army. They should not restrict their search for tuberculosis to pulmonary lesions alone, as is too often done, but should seek for tuberculous affections of all kinds, however slight they may appear. This is a service which physicians can render now to the army. The benefit from it will be felt in the near future by the whole country. [Maragliano speaks with authority as he is not only one of the leading experts on tuberculosis but is also a senator of the realm, in close touch with the government.] He emphasizes that any focus of tubercle bacilli may and does remain circumscribed and occult as long as the resisting forces of the organism are able to oppose to them an adequate defense. But once the resisting powers are weakened by any cause, the bacilli throw down the barriers, and sally forth to conquer. Among the instructive diagnostic findings in case of a pulmonary lesion, he cites elastic fibers in the sputum and detection of antibodies in the blood and of tubercle bacilli in the urine. Latent tuberculosis of the kidneys is much more common than is generally believed. In dubious cases, roentgen examination is imperative, and subcutaneous injection of tuberculin, not less than 2 or 3 mg. if there are no broncho-alveolar foci. With an existing focus, 1 mg. or less is enough. The focal reaction should never be overlooked;

this may be as marked after taking 1 gm. of potassium iodid at one dose as after the tuberculin test. It should never be forgotten that tuberculosis proceeds *in stages, now* advancing, now stopping, as the defences grow stronger. The "clinical cure" means merely that the defence is stronger than the invading host and is holding it in check. If physicians at large appreciated this, they could surround the tuberculous with precautionary measures so that many of them could live on indefinitely. They should never be exposed to the vicissitudes of army life.

74. **Unusual Manifestations of Syphilis.**—Among the cases described by Verdozzi is that of a woman of 41 with an indolent tumefaction of the right knee. The bones showed erosions and deformity on roentgenoscopy, and a bloody fluid escaped on puncturing. No benefit was derived from a plaster cast or from administration of neosalvarsan and mercury. In two other cases the clinical picture of a gastric ulcer or cancer was accompanied by a strongly positive Wassermann reaction, and, under neosalvarsan, recovery from the syphilitic gastritis was soon complete. The last case described was that of a woman of 52 with great enlargement of the spleen, chills and intermittent fever, headache and general malaise, all continuing more or less constantly for two years. Then the spleen was removed, but the fever persisted unmodified until conditions were restored to practically normal by a course of neosalvarsan.

76. **Reflex Nervous Disturbances after War Wounds.**—Valobra summarizes the opinions of the different writers on this subject of disturbances observed in a limb after a wound that did not injure directly any of the nerves or vessels. He has had a number of such cases in his care and was impressed by the element suggesting a psychoneurosis and also an element for which the hospital care was responsible, namely, overlong immobilization. This not only helped to fasten the psychoneurosis element but it induced local changes, fastening the tendency to voluntary immobilization in the form of spasmodic contracture or voluntary inactivity. The clinical picture, as he has seen it, conforms in every detail to Babinski and Froment's description of reflex nervous trouble, but he does not agree with them in their explanation of it as something independent of external circumstances. He has found that it can be cured by physical measures associated with psychotherapy. Proper surveillance of the immobilization in these cases of minor wounds, not allowing the limb to be immobilized too long, will ward off all such disturbances in the majority of cases.

77. **Associated Phototherapy and Radiotherapy.**—Milani and Capelli review the results obtained during the last four years at the institute for electrotherapy and radiology connected with the University of Rome. They also describe considerable research on the biologic, bactericidal and curative action of white and different colored lights. In lupus, by far the best results were obtained with white light (including the greater part of the ultraviolet rays and all the light part of the spectrum), especially when supplemented by radium and the roentgen rays. For torpid war wounds, red light stimulated the granulations, while exuberant granulations seemed to be favorably modified with blue light.

79. **Technic for Amputation.**—This *instalment of* Lerda's long article has twenty-one illustrations showing the different technics required for different kinds of wounds of the limbs.

80. **Suture of Tendons and Ligaments Over a Gap.**—Mosti analyzes the various methods in vogue for bridging a gap between tendon and ligament stumps. In a case of which an illustrated description is given, there was an unbridgeable space between the stumps of the patellar ligament. The upper stump was mobilized by slitting the patella lengthwise and slipping the anterior half downward until it could be sutured to the lower stump. This technic proved completely successful. The halves of the patella were fastened together with a screw.

81. **Ossification in the Kidney.**—Pirondini does not know of any case on record similar to the one he describes in which a woman of 37 had been having occasional hematuria and pains in the right kidney region for a year and later in the left kidney, with pyuria. Roentgenoscopy confirmed the assumption of bilateral kidney disease, but the intensity of the pains on the left side compelled nephrotomy and a large calculus was extracted. The patient collapsed a few hours afterward and necropsy revealed in the right kidney a triangular bone, measuring 3 by 5 mm., protruding into a cavity filled with pus. The bone was complete, that is, it had periosteum and bone marrow, but no features of a tumor. It was evidently of embryonal origin or the result of the irritation from the inflammation.

82. **Chronic Abscesses.**—Filardi describes two cases of inflammatory new growths of extremely slow development which had led to the mistaken diagnosis of cancer. The tumors were mostly hard, with purulent fusion only at one small part. The tumor was in the abdomen in both cases; the patients were men of 26 and 72. The tumors had attracted attention for four years and three months, respectively, and both were permanently cured by clearing out the focus. There was a history of operative treatment for inguinal hernia not long before in each case, but in the younger man unsuspected appendicitis was probably the main factor. In both cases only the ordinary pyogenic germs were found, and they were of slight virulence.

84 *Normal Beef Serum in Treatment of Anthrax. III. J. Penna, J. B. Cuenca and R. Kraus.—p. 91.
85 *Syphilitic Articular Rheumatism. P. M. Barlaro.—p. 93.
86 *Acute Anterior Poliomyelitis (Enfermedad de Heine Medin.) G. A. Alfaro.—p. 98.

84. ***Treatment of Anthrax with Normal Beef Serum.***—Penna, Cruenca and Kraus give illustrated descriptions of several cases out of their extensive experience with normal beef serum in treatment of human anthrax. [It was recently commented on editorially in The Journal, Sept. 29, 1917, p. 1085.] They now have a record of 140 patients thus treated, with the loss of only one, that is, a mortality of 0.71 per cent. Their latest series of ninety cases, justifies, they say, the exclusion of all doubt as to the efficacy of this treatment. At first they gave the injection intravenously, but found that the subcutaneous route is equally effectual except for the gravest cases. The dose ranged from 10 to 30 c.c. as the average, up to 40 and 50 in the most intense cases. The dose is repeated on the next and the following day at need. The serum is heated twice, and nothing has been observed to indicate production of serum sickness or allergy in any form such as is comparatively common with horse serum. In the nine severe cases described in detail, the desired result was attained with a single injection of from 20 to 30 c.c., with the exception of one case in which the anthrax pustule was on the neck. The first dose here was 50 c.c., and 30 c.c. was given later the same day on account of the alarming general symptoms.

85. **Syphilitic Articular Rheumatism.**—Barlaro says that in his experience he has found articular rheumatism of syphilitic origin more prevalent than that from tuberculosis and gonorrhea combined, and much more frequent than true acute febrile polyarticular rheumatism. . In some cases there is merely pain in the joints and functional weakness, the pains growing worse at night. As a rule the arthralgia comes on without preceding trouble, but sometimes there is a history of an acute infectious sore throat not long before. The temperature fluctuates irregularly and one or more joints may swell. In two cases described the pains developed acutely in throat, abdomen and knees in one, and in the right knee and left hand in the other, involving later the other knee and the ankles. The pain in this case was increased by movement of the joint, but there was no swelling or redness of any joint. In both cases mercurial treatment proved successful in gradually abolishing all disturbances and the general health improved. In another group of cases, of which the tempera-

ture charts are given, the joint trouble resembled deceptively ordinary febrile acute articular rheumatism. In these cases mercurial treatment only slowly conquered the joint trouble and fever, fully two months passing before the temperature was normal. In other cases the trouble was subacute and restricted to one or two joints, with brief acute exacerbations. He has also encountered chronic cases, and remarks that these are the cases of rheumatism which used to be cured empirically by mercury. Modern science has demonstrated that many forms of chronic rheumatism, from the monoarticular to deforming arthritis and rhizomelic spondylitis may yield to thorough treatment as for syphilis. In one such case the woman had a history of syphilis contracted a year or two before. The "rheumatism" developed with chills, fever and swelling and redness of the joints, especially the small joints of the hands. Under mercurial treatment the fever was aggravated at first but then declined. The clinical picture of chronic deforming rheumatism then developed with deformity of the fingers and contracture, rheumatism of the neurotrophic type, and she grew weaker and weaker. By the end of the month the dose of mercury was doubled, after which the gravest symptoms gradually subsided. The first and gravest phase lasted for seven months, comprising two severe and two minor attacks. Then under continuous mercurial treatment the woman recuperated and is now free from pain and in good condition except for the deformed fingers and feet. He cites some other cases of this tenacious form with its waves of acute exacerbation. A special feature of nearly all the cases was the greater intensity of the pains at night. There is a possibility that the peculiar tenacity of some of these cases is due to the fact that it is ordinary rheumatism occurring in a syphilitic.

86. **Poliomyelitis.**—Alfaro relates that up to 1909 acute anterior poliomyelitis at Buenos Aires had occurred only sporadically, but in that year and since the cases have been more frequent, without ever assuming actual epidemic form or special gravity. In Montevideo and vicinity last year there were about sixty cases but all were mild. He has himself encountered at Buenos Aires sixty cases during these recent years but has never seen or known directly of a case of contagion, nor been able to trace the cases through a carrier to the source. Hence he does not approve of the excessively severe prophylactic measures which some have wished to introduce in Argentina. In one instance the three children of a family developed the disease all together, with only a few hours' interval, the clinical picture suggesting influenza. One child had merely fever, prostration and mild catarrhal symptoms, soon subsiding, but in the others intense meningeal symptoms followed, to which one child of 2 rapidly succumbed while the other, a boy of 6, lay comatose for several days and then the paralyses permitted a retrospective diagnosis of the familial epidemic. The lumbar puncture fluid in both cases showed merely slight albumin content and lymphocytosis, with no bacteria. In one other case this meningeal form proved fatal from ascending paralysis. In all his other cases the patients recovered. The differential diagnosis was by exclusion and the leukopeny. The paralysis during the disease affected the legs in 75 per cent. but in some cases the muscles of the neck and trunk were involved and in one case there was eventration from the paralytic atrophy of the rectus muscle. In another there was acute incoordination of the movements of the trunk and limbs for a time. He noted the painful type in several cases, and Morquio of Montevideo reports that this type formed 70 per cent. of his cases; Marie denies the existence of this type. In one of Alfaro's cases the pain was so intense in one thigh and the contracture so severe that acute coxalgia was suspected at first, until the consecutive paralysis, pronounced atrophy and loss of the reflexes indicated its true nature. The incomplete and abortive cases must be watched for with care as they spread the disease. He had only two deaths in his sixty cases but almost all the patients, with one exception, were left with persisting paralysis. In four cases he gave intraspinal injections of serum from convalescents; the results seemed brilliant in one case but were disappointing in the others.

90 Cooperation Between Physician and Dentist. C. van der Hoeven. p. 236.
91 Meningococcus Meningitis in a Child. W. A. Weisfelt.—p. 240.

88. **Diathermy for Gonorrheal Ophthalmia.**—Kraft and ten Doesschate relate that excellent results have been reported in various quarters from the use of diathermy, electric thermopenetration, in treatment of various eye affections, including traumatic iridocyclitis, rheumatic scleritis, chronic uveitis, trachoma, vernal conjunctivitis and above all in parenchymatous keratitis. They have tried it themselves in chronic iridocyclitis, tuberculous keratitis and gonococcus eye affections. No benefit was apparent in the two first named, but in the gonorrheal ophthalmia the results were gratifying. The action of the diathermy seems to be exclusively that of heat. The heat being generated within the tissues reaches a higher degree than is possible to attain with compresses, cataplasms, etc., the benefit from which has long been an established fact. With high temperatures we attack the gonococcus on its weakest side, as it is well known that it is killed off by comparatively low temperatures. Bumm found that at 38 C., long kept up, the gonococci lost the power of reproduction. Cases are on record in which gonorrheal ophthalmia was promptly cured by application of steam. Experiments on rabbits have apparently shown that their eyes can stand the application of direct heat to 45 C. without harm.

With diathermy it is possible to reach a temperature of 42.5 C. in the conjunctiva, as can be measured by a mercury thermometer made to fit into the culdesac, the scale projecting between the lids. The temperature can also be determined from a needle introduced into the conjunctival fold, but these measures are liable to do harm. The patient's sensation as to the heat is enough of a guide. The electrode was made to fit over the eyeball; the other electrode was placed at the back of the neck. The fat and bone around the eyeball are bad conductors, so that the heat generated is retained in the eyeball, and it is retained most in the tissues which offer the most resistance to the electric current, namely, the cornea and sclerotic. The success in the first case in which they tried the diathermy was so striking that they looked eagerly for another case of gonorrheal ophthalmia, but two years passed before they encountered one among the usual run of gonococcus urethritis cases. Two hours after the first application of the diathermy for fifteen minutes, no further gonococci could be found in the secretions in the eye recently involved in the ophthalmia. Some were still found in the older process in the other eye, but they gradually disappeared and vanished completely by the tenth day. The third and last case in their experience was less satisfactory; there was already an ulcer on the cornea when first seen, and the skin of the eyelids was macerated by preceding local application of potassium permanganate and silver salt solutions. It had been rendered so sensitive that effectual diathermy could not be systematically applied, but even under its partial use the gonococci finally vanished.

89. **Pathogenesis of Tetany.**—Bolten describes the case of a young man with tetany, and then devotes the rest of his long article to discussion of the pathogenesis of tetany, as he does not believe that the parathyroids are directly responsible for more than a certain proportion of the cases. He further disagrees with those who take tetany in children lightly; he cites figures showing that complete recovery followed in only about 20 per cent. He ascribes tetany to a "spinal intoxication." When this is the work of toxic action from the parathyroids, the outlook may be grave. The tetany following removal of the parathyroids, he reiterates, is seldom or never overcome, but when the parathyroid insufficiency is only partial or transient, then the tetany may subside. In the nonparathyroid cases the toxic action on the spinal cord is usually transient, and the resulting tetany is benign, as in workman's tetany, tetany with various infectious diseases,

and with stomach or bowel trouble. The fact that workman's tetany is liable to recurrence is due to the action of the cause inducing it in the first place, especially the eating of bread made from grain containing ergot. He does not believe that there is any specific tetany poison; any poison casually acting on the spinal cord is liable to bring on tetany. In the case described in detail, the young man seemed to have a chronic, latent tetany which flared up under autointoxication from constipation, and subsided again as the bowel functioning became regular again. There was a tendency to cataract in one eye from childhood and to infantilism and defects in the enamel of the teeth—all of which Bolten regards as manifestations of the tetany of parathyroid toxin origin. They have never been observed with tetany following complete removal of the parathyroids. He explains the case, therefore, as an old chronic parathyroid tetany which keeps constantly latent until fanned into a flame by some occasional other factor, and which subsides into latency again as this factor is eliminated. He quotes from most of the recent literature on tetany but gives no bibliographic references.

92 *Thyroidism after Roentgen Treatment; Two Cases. P. Verning. —p. 741.

92. **Death After Roentgen Treatment of Exophthalmic Goiter.**—Verning reports two cases, with only a few weeks' interval, in which the vascular, recently developed goiter was given Roentgen treatment, and fatal thyroidism followed. One patient was a woman of 26; the symptoms of the exophthalmic goiter became manifest two months after delivery of her first child. She had always been nervous, and two years before had had febrile articular rheumatism, with complications on the part of the heart. The thyroid was exposed to the roentgen ray, the dose 5 H, filtered, and the exposure was repeated the next day. The circumference of the neck subsided from 36½ to 34½ in a few days, but the tremor and agitation increased to actual delirium, and the woman died fifteen days after the last exposure, a little over two months after the first signs of the exophthalmic goiter. The other patient was a housemaid of 18 with no pathologic antecedents except one slight attack of gastric catarrh and chlorosis. For the last year she had been easily tired and nervous, with a tendency to occasional palpitations and shortness of breath. She entered the hospital a month after she noticed that her neck had begun to enlarge a little. Two roentgen exposures were given with the same dose as in the other case, only with a two-day interval. Symptoms of mild thyroidism developed as the circumference of the neck became reduced from 34 to 30.5. Later the thyroid symptoms became aggravated, and the girl died about six weeks after the exposures. A mild intercurrent infectious sore throat may have been a factor in the fatal outcome. The dosage of the rays was not above the average, but must have been excessive for such recently developed cases. Verning summarizes in conclusion the cases he has found on record in which, under roentgen treatment, the symptoms became aggravated. As a rule, however, this aggravation was transient, and the result on the whole was improvement.

Hygiea, Stockholm

93 *Prolapse of the Umbilical Cord. A. Nordlund.—p. 689.
94 *Circumscribed Phlegmonous Gastritis Simulating a Tumor. Sten von Stapelmohr.—p. 708.

93. **Prolapse of the Umbilical Cord.**—Nordlund's statistics emphasize the danger from attempts to reduce the prolapsed cord. The mortality in the reduction cases was 30.2 per cent., but in reality it was still higher, as reduction had been attempted first in some of the version cases. So the version alone was not responsible for all of the mortality of 27.4 per cent. in the version with extraction cases. The total number of cases of prolapse of the umbilical cord was 5.3 per cent. of the 62,316 deliveries at the Stockholm maternity since 1850. In these prolapse cases, 38 per cent. of the infants were much below and 32 per cent. much above the average weight. The mortality in the total 333 cases was about 30.9 per cent. He gives tables of the different data as compared with those from other maternities. In not less than 52 of the 333 cases, the prolapse followed some operative intervention, and in 9 it was increased by the intervention. Attempts to reduce the prolapsed cord were made in 104 cases, but failed in 67, and 32 of the children in the latter group died. His conclusion is that in case of prolapse of the umbilical cord, extraction should follow at once, with or without version. The risk from attempted reposition of the cord is shown plainly by the data presented. While waiting for the os to dilate, the woman should be kept in the Trendelenburg position.

94. **Circumscribed Phlegmonous Gastritis.**—Stapelmohr published last year three cases of diffuse phlegmonous gastritis, and he now reports two cases in which the trouble was limited to the pylorus region. This area was resected, but instead of the supposed cancer the microscope showed merely phlegmonous gastritis. One patient was a man of 59, and the trouble began with fever and vomiting, the laparotomy following in less than three weeks. The other patient was a woman of 33, and there had been symptoms from the stomach for three years. The Wassermann test gave a positive response. Both patients were apparently cured by the operation. There were evidences of a chronic hyperplastic gastritis in the second case and in both cases there was pronounced leukocytosis. This latter might aid in differentiation.

95 *Diagnosis of Pregnancy. J. Kaarsberg.—p. 1233.
96 *The Coarse Bread Question. M. Hindhede.—p. 1248.

95. **Diagnosis of Pregnancy.**—Kaarsberg declares that he has been unable to find on record a single authentic case of actual menstruation during a pregnancy, not even in cases of double uterus. The changes in consistency in certain areas are instructive signs of pregnancy, even in the early stages. He has sought regularly for Lobhardt's "livid stripe," running from the mouth of the urethra past the relics of the hymen, but has found it in only three cases. The Abderhalden test seems to exclude pregnancy when the response is negative, but a positive reaction is not conclusive. Hegar's sign is the softer consistency of the uterus, so that it can be pressed in with the fingers above the cervix until the fingers almost meet. But Kaarsberg has never encountered this but once in his experience. A softer consistency of the uterus in the cornua is comparatively common, and very instructive, even early in the pregnancy. Veterinarians count on this in examining cows to learn if they are gravid. The cornu is easily palpated through the rectum. He regards this as more instructive than changes in the size and shape of the uterus in the first three months. In a case of pregnancy in the cornu with an eccentric growth, he operated for assumed tubal pregnancy but found the three months' ovum normally embedded. Such a mistake can be avoided by finding on palpation both cornua equally well defined. Interstitial pregnancy is often accompanied with attacks of severe pain.

In discussing the complications of pregnancy, he remarks that he has never seen but one instance of incarceration of the gravid, retroflexed uterus. The fear of incarceration therefore need not be great; the patient can be warned to apply for help if there is difficulty in voiding urine. Restoration of the uterus to place is liable to entail abortion. There can be no incarceration of the fully retroflexed gravid uterus without the cervix being drawn up and back of the symphysis. This usually squeezes the lower walls of the bladder together and impedes its emptying, but this is not always the case. Conditions are often misleading with a double uterus, the palpation findings suggesting a tumor or extra-uterine pregnancy. In conclusion he presents evidence that the condition called "supravaginal hypertrophy of the cervix" of the gravid uterus is in reality torsion of the uterus with an ovum embedded in a cornu.

96. **White or Whole Grain Bread.**—Hindhede replies to recent criticism of his research on foods and dietaries. It has been objected that the two men, the subjects of his experiments, had such unusually good digestion that conclusions from them, particularly in respect to digestion of bran, cannot apply to average persons.

THE NEW PUBLIC HEALTH *

W. S. RANKIN, M.D.
Secretary, North Carolina State Board of Health
RALEIGH, N. C.

My ambitious subject, the new public health, is not of my own choosing. A recent book has been devoted to a discussion of this subject. In attempting to deal with a subject of such vast proportions in the short period of time at my disposal, I shall be compelled to limit myself to brief references to those recent changes in point of view, new interests, and new proposals which seem to offer the biggest rewards for any attention that may be given to them.

GROSS AND ANALYTIC CONCEPTIONS OF THE HEALTH PROBLEM

Our former rather gross conception of the health problem is becoming more exact, more analytic. We are learning that the health problem has an anatomy; it can be cut up, dissected into a number of independent, smaller health problems or health units. The treatment one prescribes is profoundly influenced by one's point of view. It depends, namely, on whether one has the gross or the anatomic conception of the health problem. With the gross conception one prescribes general treatment and uses the shotgun prescription. His treatment is like the treatment of one who prescribes a physician for the sick, for he prescribes a health office or health officer for the health problem; as, for example, a national department of health for the national health problem, and a whole-time county health officer for the county health problem. With the anatomic conception one prescribes specific treatment, a definite plan for each separate health unit. The health officer with an exact conception of the health problem in treating a sick social organism does not put all of the treatment in one prescription, realizing that in aiming at everything he may hit nothing, and incidentally turn his patient's stomach. Today is the day of specific therapeutics, both for the individual and for the public. Specific therapeutics demands exact knowledge.

FEDERAL, STATE AND COUNTY COOPERATION IN FINANCING AND PLANNING RURAL HEALTH WORK

Two departments of the national government, those of agriculture and of commerce, have established a plan of financial and supervisory participation with state and county governments in local or county work in which all three participating governments have a common interest. Under this plan the federal government makes an initial appropriation of from $4,000,000 to $25,000,000 annually. This appropriation is apportioned to the states on the basis of population and square mile area, and each state apportionment becomes available when the state appropriates an equal sum. The state, in its turn, apportions the combined federal and state funds to those counties that will appropriate a supplementary fund, the amount of which the state determines. Note that all the appropriations, federal, state and county, are conditioned and are available for use only when two other appropriations are made. Such appropriations are comparatively easy to secure, one of the three contributors inducing the other two to contribute. In addition to providing funds for local work in which all three governments have a common interest, this plan offers another great advantage: before any county can receive state or federal aid, its plan of work must be approved by both state and federal participants. In this way the federal government and the state government become clearing houses of experience in formulating and directing local work.

This principle of governmental cooperation which the Department of Agriculture and the Department of Commerce have established for county agricultural work and county highway construction should be quickly extended to include county health work. A federal appropriation of a million dollars annually for rural health work, to be apportioned among the states on a basis of rural population and square mile area, and made available to the state appropriating a like sum, would give the average state $40,000 annually for rural health work. Then if the state apportioned the $40,000 to those counties that would match the combined federal and state fund dollar for dollar, the total fund in the state for rural health work would amount to $80,000 annually. Moreover, the conditions of the apportionments, in requiring the plan of rural health work to be approved by all three participating governments, would insure the highest degree of efficiency. In a recent conference of secretaries of state and provincial boards of health, appropriate steps were taken to secure from Congress the extension of the plan of financial and supervisory cooperation of governments to include, in addition to agriculture and good roads, rural health work.

INDUSTRIAL HYGIENE

Countries epitomize the course of civilization in being first agricultural and then, with an accumulation of raw products, becoming industrial. Our country is rapidly becoming an industrial nation. Multiplication of industries means that competition is sharpened by every new wheel that turns. Competition demands the elimination of waste.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Waste in industry results (1) from defective machinery, and (2) from defective manipulation of machinery. The successful industrial captain demands that only the best machinery be installed, that it be kept clean, polished, well lubricated, screws and bolts tight, belts well adjusted, and in every way physically fit. He does more. He looks beyond the machine and finds that a physically efficient machine in the hands of a physically inefficient operator means waste. He finds that from 40 to 50 per cent. of employees are sick or abnormal some time during the year. He finds that each abnormality, total incapacitation, is preceded and followed by subnormality, partial incapacitation, of from two to three weeks' duration; in short, he finds that the average worker is partially and completely incapacitated for about one twelfth of his time. He finds that accidents to both men and machines occur usually to those men and machines that are physically either subnormal or abnormal. He finds that the product of a machine suffers quantitatively and qualitatively when the machine stands idle as a result of an abnormal operator, or when the machine is under the manipulation of a subnormal operator, and so the need, the demand for industrial hygiene gains new strength almost daily. In supplying this demand, the great need is a carefully devised, detailed plan of industrial hygiene built up in units and made thereby adaptable to the more important industries of varying capitalization.

IMPROVEMENT IN PUBLIC HEALTH THROUGH ADVANCES IN PRACTICE OF MEDICINE

The medical profession conceived public health, fed the embryo from its own blood, brought forth the mature infant, which, though vigorous and promising, is even yet dependent on its mother's breast. Anything that strengthens the mother helps the child. In this country recently three proposals, health insurance, group practice, and a plan for more generally available postgraduate courses for physicians, have been put forward for the purpose of advancing public health by improving the practice of medicine. The first two of these proposals, health insurance and group practice, are being well cared for by able men.

Organized medicine has taken a deep interest in medical education, as medical education applies to the physicians of tomorrow; but in its solicitude for the undergraduate it has apparently forgotten the postgraduate, the present field force of something like a hundred thousand physicians. Modern governments do not appropriate money for road construction without providing in the act for the maintenance of the roads constructed. The solidarity of the medical profession depends on two conditions: (1) its construction, and (2) its repairs. The repair shops of medicine are sorely inadequate, and with a very few exceptions those that exist are not organized with proper consideration for the convenience of the men who should use them.

Eighty per cent. of the general practitioners get little or no postgraduate work. Their income is small, around $1,500 to $1,800 a year. They have family responsibilities, current expenses and insurance. The present cost of postgraduate work is in excess of what the general practitioner can pay. To make postgraduate work more generally available, one of two things must be done: either the income of the profession must be increased or the cost of postgraduate work must be decreased. In order to decrease the cost of postgraduate work, let us analyze its budget. Let us suppose, for illustration, that seventy-five physicians take a postgraduate course of six weeks in diseases of children under a capable assistant professor in one of our larger medical schools. The teacher has graduated three or four years previously, is an exceptionally well qualified man, and is one of the best of the younger men in the active teaching force. Let us assume that the physicians taking this course collect $150 a month from their practices. The individual expense account then will be:

Absence from practice six weeks	$225
Tuition six weeks postgraduate	100
Traveling, board and incidentals	75
	$400

For the entire class of seventy-five men, the cost will be seventy-five times $400, or $30,000.

Now let us suppose that we reverse the transportation process: Instead of moving seventy-five men away from their practice to one man, the teacher, let us move the teacher to the seventy-five men, leaving the men at work in their practices during their postgraduate courses. The seventy-five doctors can be grouped into six sections of from twelve to thirteen men. The sections can be so located with reference to each other that the teacher can meet Section 1 on Monday for an hour's lecture and two hours' clinic, travel a distance of from 20 to 30 miles, meet Section 2 on Tuesday for three hours' work, and so on, Section 3 on Wednesday, Section 4 on Thursday, Section 5 on Friday, and Section 6 on Saturday; and with the sections arranged on a circuit the teacher would be, on completing his week's work on Saturday with Section 6, within one hour of Section 1; with which on Monday he would begin again his weekly cycle. In a three months' course each section and each member of the class would receive twelve hours of lectures and twenty-four hours of clinics; or in a four months' course, sixteen hours of lectures and thirty-two hours of clinics. If we pay the teacher $600 a month for a four months' course, the teacher will receive $2,400; if we pay the teacher $800 a month for a three months' course, the teacher will receive $2,400, which is not bad pay, at least from the point of view of the general practitioner. If we allow an additional $600 for other costs, such as laboratory material, stenographic reports of lectures, etc., the total cost of the course to the entire class will be $3,000, which will be agreed on in advance and raised by assessments of $40 for each member of the class. The amount of clinical material needed can be prorated among the members of the class, who can furnish this material from their practices. The state university, the state board of health, or some other state agency of standing should assume responsibility and direction of the course. If the university should assume direction of the course, academic credits could be issued to those who satisfactorily complete the course.

There are only four elements that enter into postgraduate work: (1) a class room, (2) a class of from eight to fifteen physicians, (3) a qualified teacher, and (4) clinical material. In times past this combination could be effected in only a few large cities; but times change, conditions and environment change, and men, except the aged that have lost their adaptability, change. Improved railway facilities, excellent highways, the automobile, denser populations with more abundant clinical material, increase in number of physicians and decrease in space separating them, are factors that could be and should be utilized in the repair of the medical profession, in bringing mental sustenance to the men in the trenches, instead of sending them far back to a few base kitchens.

THE NEW IDEAL: VITAL QUALITY

In health work the old ideal was quantitative — more life, lower death rates, greater longevity. The new ideal will be qualitative — greater human efficiency, a better quality of being.

There was a time when mere quantity of service counted for more than it does today. Then we had a work day of twelve hours and a school day of eight or nine hours. Now we know that a man's ability to produce and a child's ability to learn is greater with an eight hour work day and a five hour school day than with the former longer hours. The time may come when we shall find that a life adjusted to a fifty year time table makes greater mileage on the energy consumed than does a life adjusted to a seventy year time table.

Quantity of life and quality of life are related, but are not identical. If we provide for quantity we do not necessarily insure quality. If, on the other hand, we provide for quality of being, we take care of quantity so far as it deserves to be cared for. With the old ideal of vital quantity, those diseases that have large mortalities and high degrees of preventability tended to absorb our thought and energy. With the new ideal of vital quality, we shall be not less mindful of those diseases that directly affect vital quantity, but we shall be more mindful of those diseases that play havoc with vital quality. The light hookworm infection; twenty to fifty parasites; the neutral malarial infection; the chronic suppurating gums; the chronic constipation; the grumbling gallstones; the nagging piles; the old, slightly lacerated cervix; the improperly balanced ration; the excess of nicotin; the improperly ordered schedule of rest and play and work; these, and their like, gage the severity of their attack on vitality by what the vital forces will tolerate without striking back. These, like the small tax gradually increased over long years, take from a careless people a total of efficiency, of vital quality, of life, that, could we but compare it with our account against tuberculosis, typhoid fever, and their like, would make the last named diseases appear of far less relative importance. Our vital losses, like our financial losses, are in driblets, pennies, nickles, dimes, an occasional quarter. If these little drafts on efficiency, on vital quality, the individual items too small to add from day to day, were totaled at will-making time, our conception of the relative importance of diseases would undergo a rather remarkable revision. Periodic examination of adults, as carried out by the Life Extension Institute; medical inspection of schoolchildren; school lunches; the accentuation of the fight on diseases that cripple rather than kill, hookworm and malaria; the oral hygiene movement; the mental hygiene movement; the propaganda of the eugenist; the increased interest in the regulation of working hours, in dietetics, are all aimed not primarily at death rate reduction and longevity extension, quantity, but at the new ideal, a finer quality of being. For

> We live in deeds, not years; in thoughts, not breaths;
> In feelings, not in figures on a dial;
> We should count time by heart throbs. He most lives
> Who thinks most, feels the noblest, acts the best.

ABSTRACT OF DISCUSSION

Dr. H. M. Bracken, Minneapolis: Dr. Rankin has given us a most interesting paper, illustrating the work that is already being done in North Carolina relative to (1) organization of county boards of health, and (2) postgraduate teaching. Both of these are of the greatest importance. Dr. Rankin is to be congratulated on what he has been able to do, as well as on the able way in which he has presented his subject. It is to be hoped that others may follow his example. The plan which he has developed for postgraduate work is unique, but seems to be efficient.

Dr. W. C. Rucker, Washington, D. C.: Last year at Cincinnati I defined health as the physiologic function of the community. This caused a little smile to ripple over the face of things; but, after hearing this paper, I am convinced more than ever that this definition is correct, and that health is the physiologic functioning of the community. In our health teaching heretofore we have taken the wrong course, the illogical way, of going about it. We have reasoned from the pathologic to the physiologic instead of taking the point of view that the normal is the physiologic.

Judged in that way, we get far away from the idea that the whole problem is a communicable disease problem, and realize that it is a community problem. In this problem we must recognize two sets of workers: the general practitioner and the group of people whose practice is limited to public health work, or sanitation.

This gives us an opportunity to give different sorts of training. We should give the same basic training to all; but to the man whose practice is to be limited to sanitation, we should give intensive training along certain definite lines, developing each man according to his special capabilities for special lines of work. With regard to the school curriculum, to the postgraduate course, it seems to me that there is one psychologic factor that should be borne in mind, and that is that when men gather together in a new environment for the purpose of accomplishing something, they can do that something better than they could in their normal environment.

Dr. Haven Emerson, New York: In paying tribute to Dr. Rankin's admirable conception of the opportunities that await postgraduate education in public health matters, I wish to emphasize the fact that failure of the practitioner at present is due to the failure of medical schools to appreciate that the teaching of diagnosis and care of the individual is not the sum of their responsibility to their students. Rarely is a student's attention called to his responsibilities to the community in fulfilling his obligations to patients. There is no reason why the local health officer should not play a part in the postgraduate teaching of clinicians and physicians just graduated from hospitals.

We are now in the presence of the phase of public health work which recognizes that the habits of the community, and the education in personal hygiene of the individual will be the determining factor in further improvement of public health. Health officers must become teachers, so that the people will know how, when they are healthy, to keep healthy. They must spread the newer knowledge of physiology; the knowledge that alcohol is not a stimulant but a depressant; the knowledge that the best preventive against venereal disease is personal continence, and the knowledge that continence is compatible with health. I believe that we could proceed in this matter without waiting for governmental appropriation, and that it needs merely cooperative organization between existing medical schools and the health officers, in order to put into effect a program for postgraduate public health instruction of clinicians.

Ultimately, this teaching work should be paid for by government subsidy or by the medical school, but volunteers could doubtless be obtained to put the plan into operation, with confidence that support would come as its value was recognized.

Dr. Arthur T. McCormack, Bowling Green, Ky.: Dr. Rankin has put into practice plans and thoughts which have suggested themselves in part to many of his fellow workers. He has actually done what others have dreamed of. Congress at its last session made an appropriation of $150,000 to be used for cooperative work with the states, on the dollar for dollar basis, in rural sanitation. To my mind this really activates the United States Public Health Service; and, regardless of whether we have a cabinet officer now or later, it gives us a federal health service that will be enabled to standardize county health departments so far as this is possible. A county which expends $5,000 annually on its health department will now be able to secure a sanitary survey of every home and individual in its borders by trained medical officers. Such a health inventory will enable the health officer and his corps to know what problems should be solved first and to adopt a compresensive, economical plan for such solution. Such a survey will do more for the education of all the people of a county than can be accomplished in a generation by other means. The careful sanitarian, made practical by experience, who goes to the home and takes up the details of ordinary life, answers questions, and tactfully points out defects and at the same time demonstrates the remedies for these defects, is the real apostle of health.

Dr. Rankin emphasizes the evolution going on in all of us, and Dr. Emerson well says that the local health department must concern itself with every single thing that goes to make a better citizen for that community. It was but recently that we all felt that an all-time health officer was the "ultima Thule" of our desires. Before we have secured him, we know that, alone, the most devoted all-time health officer will, in many counties, be wholly inadequate. What we must have is an all-time county health department, with such force and such allies as are necessary to prevent sickness and restore those who are inefficient.

EXPERIMENTAL SHOCK *

C. C. GUTHRIE, M.D., Ph.D.
PITTSBURGH

In view of the desirability of prompt publication of results in this field, as indicated recently by Pike,[1] a summary of work conducted by the staff members of this department and extending over a number of years[2] is deemed timely.

The general plan was to devise a reliable and comparatively simple method of producing shock; to establish definite criteria for recognizing the condition and to observe and study (quantitatively when possible), at frequent intervals throughout the experiment, as many phenomena simultaneously as was feasible, for we were proceeding on the assumption that the grosser manifestations of shock are to be considered effects rather than causes. Accordingly, if the causative mechanism was to be observed, it would be most desirable to study minutely the phenomena immediately preceding, during and following the application of the means used for producing shock, and to observe the effects of such therapeutic measures as might be indicated by the results.

Such experiments were made on twenty-two dogs. The studies comprised blood pressure; pulse rate and character; vasomotor reflex response; vasomotor tone; respiration rate, amplitude and regularity; volume and composition of expired air; blood hydrogen-ion concentration, reserve alkalinity, hematocrit and hemoglobin tests, red cell count and specific gravity determinations (from which alterations in the composition of the blood, as regards relative volumes of plasma and corpuscles, as well as estimations of relative changes in total volume of blood, were made); estimation of the total blood contained in the vessels of the alimentary canal and in the vessels of the liver; viscosity and depression of the freezing point of blood, and temperature and condition of the general reflexes (eye, knee, etc.). Comparative studies were made on conditions observed in shock, and conditions following induction of cerebral anemia. The effects of remedial measures were observed, as mechanical increase of cerebral pressure, by occluding the aorta; elevation of the posterior portion of the animal to facilitate return of blood to the heart, and administration of drugs, including epinephrin, tyramin, atropin, sodium bicarbonate, lactic acid, and inhalation of carbon dioxid.

METHOD OF EXPERIMENTATION

After such observations had been made as were possible on the unanesthetized animal (condition, general behavior, pulse and respiration), it was quickly reduced with ether to a state of surgical anesthesia, and operated on. A trachea tube was inserted and connected with an ether bottle provided with valves. Connections were provided for collecting expired air samples for analysis. A mercury manometer was connected with one carotid artery for recording blood pressure. Blood samples were obtained by means of a cannula inserted into a carotid or a femoral artery.

After the taking of observations, including tracings and samples of air and blood to establish the condition under ether only, the brachial plexus on one or both sides was exposed, ligated and cut peripheral to the ligature and further stimulated by traction, or crushing with forceps, and by tetanizing electric currents. One or both sciatic nerves were prepared for stimulation chiefly to observe vasomotor reflex response. Unless pronounced symptoms of shock were soon induced, one or both of the fore limbs were about three fourths amputated, or the abdominal cavity was opened by a median incision and the intestines exposed and manipulated. The rectal temperature was taken at intervals. Ether was discontinued as early as possible, but was readministered, if indicated, to prevent return of conscious sensibility. Cerebral anemia was induced by the occlusion of appropriate arteries.[3]

RESULTS

Circulation.—Blood Pressure: This showed marked variations under experimental procedures. With pronounced evidences of shock, there was always low blood pressure. Usually, when below 70 to 50 mm. under ether, a tendency to recover was absent, but on removal of the ether, recovery was prone to take place, while from levels between 50 and 40 mm., the tendency to recover on removal of ether was feeble or absent. From the 50 to 40 mm. level, in general, the tendency of the blood pressure was gradual decline, but the rate of decline varied in different animals.

In pronounced shock, tying the portal vein, or tying the vein and the arteries supplying the alimentary canal and liver, had small effect on the blood pressure. Elevating the posterior trunk in such conditions caused a marked rise in blood pressure, and the effect was not materially lessened if, prior to elevation, the portal vein was ligated.

[3] Stewart, Guthrie, Burns and Pike: Jour. Exper. Med., 1906, **8**, 289.

Pulse, Rate and Character: The pulse in general varied with the blood pressure, and as pressure declined, the total effect on the pulse rate was a decrease as compared to the stage under ether only. There was no pronounced evidence of vagus inhibition.

As indicated by the manometer tracing, the character of the pulse showed variations associated, as a rule, with pressure changes and due, it is believed, to a large extent to mechanical alterations, as the blood supply to the heart, changes in peripheral resistance, and rate of heart. The pulse became weaker with lower pressures with a noticeable tendency, as compared to the stage under ether only, to become slower.

Vasomotor Reflexes: Reflex vasomotor augmentation varied in different experiments and also in the same experiment. In some instances it was diminished, and in others it was more pronounced in the lower stages of blood pressure. Its occasional absence may have been due to the ether factor. Under strong brachial nerve stimulation, augmentation was followed usually by diminution of blood pressure.[4] The diminution, too, varied in different experiments, and in different stages of the same experiment.

Vasomotor Tone: The vasomotor tone results were pronounced. For example, in one experiment under ether only, division of the sciatic nerve increased the blood flow from the femoral vein 22 per cent., while after shock in the same animal, the increase amounted to 76 per cent. In another experiment, the increase in shock after division of the nerve was 77 per cent. Hence, it would seem that vasomotor tone was present in the limb in shock, which confirms again the findings of Seelig and Lyon.[5]

Blood.—Reaction: The hydrogen-ion concentration of the blood showed a tendency to increase. For example, in one experiment, before shock the hydrogen-ion concentration was 7.2, and after shock 7.1, and in the final stages 7.0. In another experiment, under light ether only, it was 7.2, and under deep ether only, 7.0, and after shocking the animal it remained at 7.0. It would seem, therefore, very important to consider the anesthetic factor in interpreting such results.

Reserve alkalinity seemed to bear a closer relation to shock than hydrogen-ion concentration. In one experiment, reserve alkalinity decreased from 8.0 to 7.8 in the early stage of pronounced shock, and as the degree of shock increased, reserve alkalinity decreased to 7.1. In this experiment, reserve alkalinity before shock was 8.0, in pronounced shock 7.3, and in the very late stages 7.1. The hydrogen-ion concentration in this experiment increased from 7.2 to 7.0.

Hydrogen-ion concentration determinations were made by the Levy, Rowntree and Marriott method,[6] and reserve alkalinity by Marriott's method.[7] The figures obtained are taken as showing relative rather than absolute values.

Hematocrit, Hemoglobin, Red Cell Count and Specific Gravity: The relative volume of corpuscles (by hematocrit and by gravity sedimentation) hemoglobin (by Duboscq colorimeter method), number of red blood corpuscles per cubic millimeter, and specific gravity (by weighing) all showed a moderate progressive decrease. In a typical experiment, the hematocrit reading decreased from 64 per cent. before shock to 56 in the later stages; the hemoglobin, from 100 per cent. to 80.9 per cent.; the red cell count showed a decrease of about 25 per cent.; the specific gravity, from 1.068 to 1.062.[8]

Relative Blood Volume: As estimated from hematocrit, hemoglobin, red cell count and specific gravity results, there was a progressive increase in relative blood volume.[9] In the experiment quoted in the preceding paragraph, the following figures were obtained: volume of blood before shock, 100 per cent.; volume of blood in profound shock as estimated by hematocrit, 114 per cent.; by hemoglobin, 124 per cent., and by specific gravity, 119 per cent.

Distribution: In profound shock, the veins and the arteries of the alimentary canal, including those of the stomach and the small and large intestines, the pancreas and the spleen, were ligated, and after the removal of the vessels from the body, the blood was obtained by perfusing them with salt solution, and the total quantity was estimated (colorimetrically). Compared to the total blood (estimated by taking one fifteenth of the body weight), in two animals, the amount was found to be less than one seventh of the total. The amount of blood contained in the liver was less than one ninth of the total.[10]

Viscosity: Viscosity of the blood (defibrinated) showed a small progressive decrease.[2]

Depression of Freezing Point: The freezing point showed small and not significant changes.[2]

Respiration.—Rate, Amplitude, Regularity and Volume of Expired Air: In general, the total effect on the respiratory rate was a decrease from the rate under ether only. The decrease became more pronounced in the later stages of profound shock. Reflex augmentation was greater in the earlier than in the later stages. Under prolonged nerve stimulation, the reflex effects gradually diminished. The anesthetic factor renders it difficult to draw definite conclusions in all cases.

Amplitude varied in different stages of shock, and variations associated with reflex stimulation of the respiratory center introduced irregularities both of rate and of amplitude. In general, in the later stages of shock there was an increase in the amplitude, that is, depth of respiration.

With sudden onset of shock the respiratory sounds became softer. This may be associated with a change in the volume of tidal air, or with a change in inspiratory or expiratory time. In the later stages, irregularities became more pronounced, and not infrequently a type of irregularity consisting of alternate deep and shallow movements, often of group form, occurred. A type of respiration was observed in which there was a pronounced and prolonged inspiratory pause. In another type, inspiration was prolonged without much change in rate of expiration.

The volume of expired air of course varied with the rate and the amplitude. The total effect varied in different experiments, but in general, there was a decrease in the later stages.

Volume of Oxygen Retained and Carbon Dioxid Produced: The volume of oxygen retained varied greatly, not only with variations in anesthesia, nerve stimulation, etc., but also in shock, as compared to the stage under ether only. In different animals, under ether only, it varied greatly. This was true also in shocked animals. In general, in deep ether anesthesia, there was a decrease in oxygen retained. It seems that such variations are incidental rather than causal.

Carbon dioxid production varied greatly but not quantitatively with oxygen. Remarks on oxygen in general apply to carbon dioxid, including decreased production under deep anesthesia.

In harmony with the statements concerning oxygen and carbon dioxid, the respiratory quotient showed great variations.

Temperature.—There was gradual decrease in temperature, in some cases amounting to from 3 to 5 degrees, but there was no evidence of a direct relationship to shock.[11] Good recovery from shock was obtained after the temperature had decreased more than 3 degrees.

General Reflexes.—The chief somatic reflex observed was the eyelid to touch of the conjunctiva. In profound shock, after the discontinuance of ether, this reflex was maintained even at very low blood pressure levels. Other reflexes were rarely permitted to appear.

Cerebral Anemia.—Studies of cerebral anemia in relation to shock were made indirectly by comparing the condition in shocked animals with the condition induced through decreasing the circulation to the brain and upper cord; by comparing the effect of restoring or accelerating the cerebral circulation, on the manifestations in the two conditions, and by comparing the results obtained by administering drugs. We are not able to differentiate sharply between the ultimate condition induced through nerve stimulation and general tissue trauma, on the one hand, and the condition induced through interruption of cerebral circulation, on the other. Likewise, restorative measures led to very similar changes in the two conditions, for example, reestablishment or acceleration of cerebral circulation led to recovery of, or improvement in, cerebral function if instituted not too late. Such results followed restoration of cerebral circulation either by mechanical means, as aortic occlusion, or raising the general blood pressure, as by intravenous administration of epinephrin solution. In either case, drugs exhibiting potency only through action on the higher nervous tissues are inefficacious.

In two instances showing profound symptoms, one induced through nerve stimulation and trauma only, and the other associated with cerebral anemia produced by arterial occlusion, the pons, medulla and upper spinal region were kindly examined by Professor Klotz for fat emboli, with negative results.[12]

Remedial Procedures.—In shock of moderate degree under ether, prompt recovery was obtained on discontinuance of ether; but in severer grades this did not suffice. Elevation of the posterior portion of the animal to facilitate the return of blood to the heart led to recovery, but it was more efficacious when coupled with temporary aortic occlusion.

In profound shock, epinephrin in salt solution administered intravenously has promptly increased the general blood pressure, accompanied by improved action of the bulbar centers, particularly that of respiration. Gradual and prolonged administration of the drug would seem to offer advantages over intermittent injections in that recovery of cerebral function is more successful with a more evenly maintained arterial pressure than is the case with intermittent injections. Intra-abdominal administration had but slight effect.

Tyramin, intravenously, gave results that were disappointing. In magnitude, the effects were less than in unshocked animals.

With atropin only a mild stimulating effect on respiration was obtained, which was due presumably to direct action, as there was scarcely any effect on blood pressure. Such action, however, is not considered beneficial, as the center rapidly became exhausted.

A beneficial influence was obtained with sodium bicarbonate intravenously in that there was some rise of blood pressure,[13] but this was not of sufficient magnitude to establish an adequate cerebral circulation.

With lactic acid intravenously, contrary to expectation, slight beneficial effects were obtained, similar in character to those observed with sodium bicarbonate.

Administration of carbon dioxid by inhalation in profound shock was without beneficial action. Theoretically, in much earlier stages it is possible that it might be of benefit, that is, if administered at a time when the centers were capable of response to stimulation without immediate exhaustion.

Though observations with some of the drugs are too limited in number for final conclusions, we are strongly impressed with the greater promise of epinephrin than with any of the other drugs studied. Preventive studies were not undertaken, owing to the great variations in susceptibility of different animals.

COMMENT

Shock in man may be classified as (1) psychic, (2) traumatic, (3) psychotraumatic and (4) surgical. The fourth type is merely the first, second or third plus the anesthetic factor. In the dog the psychic factor is small or nil, the second and fourth being the predominant types, that is, traumatic or, as in these experiments, ether plus trauma.

Susceptibility varied greatly in different dogs. Some animals readily succumbed to brachial nerve stimulation alone; others only when nerve stimulation was combined with opening of the abdominal cavity and visceral manipulation; while others were highly resistant under both methods. Corresponding with this, the tendency to recovery on discontinuance of the stimulation was very different in different animals. In general, the more vigorous animals have been most refractory.

The anesthetic factor was most difficult to evaluate in interpreting the results. Since full surgical anesthesia was maintained until the condition of shock was pronounced (as judged by low blood pressure, etc.) the interpretation of all results up to this point involves consideration of this factor; and, since in no instance an animal was knowingly permitted to regain consciousness to pain, experiments in which recovery tendencies were pronounced and it was necessary to readminister ether were complicated even further by this factor. It is most important to maintain a uniform anesthesia, and in some of the animals this was not realized to the same degree as in others, owing to individual differences.

[11] Kinnaman: Internat. Jour. Surg., 1904, p. 378.

[12] W. T. Porter (Boston Medical and Surgical Journal, 1917, **176**, 248, 699) has studied the relation of fat embolism to traumatic shock, particularly when associated with fracture of bones.

[13] Seelig, Tierney and Rodenbaugh: Am. Jour. Med. Sc., 1913, **146**, 195.

Not all of the animals exhibited unequivocally the condition of surgical shock. This question is difficult to discuss owing to the variety of views as to the picture of such experimental shock.

Surgical shock in man, typically at least, is an easily recognized entity. In the dog, as it occurs in regular surgical work, it is also very definite, though the impressions one receives are more intense in certain cases than in others. This is probably due to the suddenness with which it develops, sometimes it being very acute and pronounced, and again of slow onset. In the acute type, which has been observed to develop with great suddenness and intensity in operations involving one brachial plexus, death may occur within a very short time, that is, less than an hour; while in the type of slow onset, the first intimation may be what appears as undue prolongation of recovery from the anesthetic. An animal in this condition may live for some hours. After being once observed, both types are readily recognized. It was the acute type we tried to induce, and in some instances succeeded beyond question. As it was not feasible to prolong the experiments, the animal, if it did not succumb within a few hours, was killed with ether; in the case of refractory animals, therefore, we cannot say that a fatal type of shock was produced.

We are inclined to consider two grades of shock as having occurred in these experiments, one associated with the characteristic clinical manifestations, particularly a marked and persistent lowering of blood pressure, but with a pronounced tendency to recover on discontinuance of the anesthetic; and the other characterized by more profound symptoms, including a persistently lower blood pressure level with no tendency to recover on removal of the anesthetic. As previously indicated, it would perhaps be better to speak of this condition, at least its later stages, as collapse.[14]

Results indicate that both reflex augmentation and diminution of blood pressure may be greater or less either actually, or in terms of per cent. of blood pressure, after the pressure has been lowered by means applied with the view of inducing shock. Even when the blood pressure has reached a comparatively low level, augmentation or diminution may be obtained by sensory nerve stimulation. But it is well to note that the data do not permit differentiation between effect due to action on bulbar centers, and possible effect due to action on peripheral or accessory centers.

Neither is it possible to analyze closely the factor of "automatic" vasomotor center activity or tone; but direct inspection of the splanchnic vessels clearly revealed at least a moderate state of engorgement in shock, which would indicate lack of vascular tone in this region. The engorgement was not maximal, as was shown by increased redness on handling the intestines; therefore some vascular tonicity must have been present; or an active process of dilatation, or paralysis, was induced through handling. We have confirmed Seelig and Lyon's[5] observation that an increased venous blood flow from a limb of an animal in shock follows section of the sciatic nerve. But this fact, as pointed out by Bartlett,[15] does not prove that the degree of activity of the vasomotor center is greater in shock.

It is known from studies in cerebral anemia that the resistance and recuperative powers of the respiratory and vasomotor centers are quite similar.[16] And even though not identical in these respects, it is perhaps permissible in the absence of more direct observation approximately to judge of central vasomotor activity by the state of the respiratory center. From this standpoint, it would seem that in profound shock probably the vasomotor center is in a state of deranged functional activity, grossly comparable to the derangement of the respiratory center. In this connection certain other considerations should receive mention, as the similarity of sensitiveness of the respiratory and vasomotor centers to sensory nerve stimulation and their similar susceptibility or resistance to fatigue under such conditions. A point of particular interest is the gradual disappearance of augmentation under prolonged sensory nerve stimulation. Whether this is due to fatigue or other form of interference with conduction, or to other form or forms of mechanism, is not clear; but it is an interesting fact that under such conditions, stimulation of another afferent nerve may affect activity of both respiratory and vasomotor centers. These observations, we believe, furnish additional support for the view that, grossly speaking, under such experimental conditions, activity of the respiratory center may be taken as an approximate index of vasomotor activity. The greater functional development of peripheral vasomotor regulating mechanisms is another possibility to be taken into account.

Though reserve alkalinity in certain cases showed a marked decrease, it is by no means certain that in all cases there was a material decrease prior to the onset of pronounced manifestations of shock. The results indicate that much of the decrease observed occurs after pronounced symptoms have become manifest. For example, in one experiment, in the early stage of pronounced symptoms of shock, there was a decrease from 8.0 to 7.8, while in a late stage the decrease had continued to 7.1. That good recovery of cerebral function was obtained (by aortic occlusion) without changing the values for hydrogen-ion concentration or reserve alkalinity is strongly indicative that the cerebral manifestations of shock are not due to change in blood reaction.

Physical measurements of blood, including viscosity and depression of the freezing point, did not reveal alterations of a kind or magnitude considered sufficient to account for shock phenomena. The alterations observed were probably associated with hemorrhage due to withdrawal of blood samples; for example, entrance of lymph, and other experimental conditions, such as decreased renal activity.

The basis of calculating blood volume changes was the relative proportion of corpuscles to plasma, and the results are expressed in terms of per cent. of the volume at the time of taking the first sample. The figures when corrected for the blood lost through hemorrhage indicate, as a rule, an actual increase in total blood volume.

The recovery of less than one fourth of the estimated total blood from the engorged vessels of the alimentary tract and of the liver does not indicate that serious pooling of blood occurred in these areas. Also, the fact that with low blood pressure, marked improvement was obtained in return of blood to heart on elevation of the posterior portion of the animal after the portal vein had been ligated, supports this view. The inadequacy of cardiac massage alone in raising pressure in such conditions, and the efficacy of aortic occlusion only, indicate that low pressure is not due to cardiac muscular inefficiency; while the prompt and marked increase in pressure following elevation of the animal's hind quarters with the portal vein ligated indicates that low pressure is associated with decreased cardiac output, and that pooling of blood is not due necessarily to portal stagnation.

[16] Stewart, Guthrie, Burns and Pike: Jour. Exper. Med., 1906, **8**, 289. Guthrie, C. C.: Blood Vessel Surgery, 1912, p. 318.

Respiration studies showed such variations and irregularities that it is not possible to make satisfactory generalizations. Attempts to determine the carbon dioxid tension in alveolar air were abandoned owing to lack of a satisfactory method of obtaining samples.

Temperature did not appear to be a causative factor. In all cases the total effect was a gradual decline. Pronounced shock was obtained when the decline was but a fraction of a degree. On the other hand, good recovery was observed after the temperature had decreased several degrees. Probably temperature change was incidental largely to experimental procedures (exposure of animal, etc.) rather than causative of shock. Good tendency to recovery exhibited with lowered temperature substantiates the correctness of this view.

As pointed out by Pike,[1] it is improbable that levels of blood pressure observed in shock would in all cases alone account for the condition apparently due to cerebral anemia. But in such experiments, activities of the central nervous tissues and hence their circulatory demands are increased, as by sensory nerve stimulation.[17] Therefore, it is difficult or even impossible in a given case to state that the tissue circulatory demands are being met even with only comparatively low blood pressure. From this standpoint, the evidence indicates fatigue of the nervous tissues as a causative factor of considerable magnitude.

One experiment was particularly interesting as illustrating this view. Although one carotid artery was not occluded, the symptoms were induced quickly, and simulated those of profound and fatal shock, including the late presence of eye reflex. This is interpreted as due to relatively greater anemia of bulb than of higher brain, which would explain the longer persistence of the eye reflex as compared to the results obtained by a more uniform decrease of cerebral circulation. Indidirectly, it substantiates the view that the interpretation of the persistence of the eye reflex in shock at a time when bulbar centers show marked derangement, in comparison with its rapid disappearance on sudden occlusion of all cerebral arteries, is probably due to lessened resistance of the bulbar centers to anemia through stimulation resulting in their greater fatigue.[18]

SUMMARY AND CONCLUSION

We are inclined to attribute the earlier stages of the condition termed shock, observed in these experiments, largely to degradation and fatigue of the bulbar centers due to ether poisoning, and to sensory nerve stimulation; and the more profound stages, to inadequate circulation to meet the bulbar tissue demands.

Though all of the blood circulatory phenomena are closely related and interdependent, perhaps the lowered capillary pressure and hence the sluggish return flow of blood to the heart, rather than chiefly venous dilatation, is a more comprehensive standpoint from which to picture the condition in shock. Among probable early derangements augmenting the condition are vasomotor changes affecting venous tone.

Treatment when instituted in the earlier stages yielded good results; in later stages, results were less satisfactory, owing presumably to irreparable injury to the central nervous system.

Therapeutic measures capable of restoring an adequate cerebral circulation, instituted before irreparable tissue injury had occurred, led to recovery. Such measures should be preferably of a mechanical nature, as elevation of the posterior parts of the body, with the view of increasing a return of blood to the heart and adding a hydrostatic factor to the cerebral blood pressure; increase of peripheral resistance as by aortic compression; and particularly when associated with severe hemorrhage, increase of blood volume by transfusion of blood or the intravenous injection of isotonic nontoxic solution, as sodium chlorid.

Theoretically, and from the standpoint of increase in blood volume only, injection of hypertonic solutions would be indicated. The recent observations of Sansum[19] on the marked increase in arterial blood pressure associated with and following intravenous injection of strongly hypertonic glucose solutions are suggestive.

Temperature, if low, should receive attention. The main indication, however, is promptly to institute and to maintain an adequate cerebral circulation.

In the case of drugs, the best results have been obtained with epinephrin solution intravenously. Drugs should be selected with the view of increasing the peripheral resistance and augmenting the return of blood to the heart by direct action on the blood vessels.

We believe that these considerations of treatment, with added considerations to meet the psychic factor, apply to shock in man. For example, as previously discussed,[20] in acute psychic shock, inhibition probably plays a leading rôle. In the series of experiments herein reported, there was little evidence that inhibition was a factor.

Free Dispensaries and the War.—At the annual meeting of the American Hospital Association at Cleveland, September 14-18, in discussing the effect of the entry of hospital and dispensary interns into the military medical service, a number of hospital superintendents intimated that the work of their institutions would have to be curtailed. It was indicated that this matter is being brought to the serious attention of hospital authorities. The idea was combated by authoritative speakers who argued that the special needs of war times called rather for an extension of their work in the communities. The discussions revealed that the idea of pay clinics for people of moderate means is making gradual headway in the hospital world. A new development of the dispensary idea is the establishment of special clinics for treating accidents under the state workmen's compensation laws. Under these laws, with the liability of the employers for the medical care of the injured workmen, the hospital will transfer to the new self-supporting clinic, in which the medi- cal staff is paid, a large amount of work which was formerly done free in the hospitals. It was said that the largest clinic, that at the New York Hospital, last year had a gross income of $35,000, and that of the Pennsylvania Hospital in Phila- delphia, $10,000. It was the sentiment that these pay clinics for general surgical work will spring up rapidly in all states having workmen's compensation laws.

THE VALUE OF EYE-GROUND OBSERVATIONS IN RECENT CASES OF FRACTURE OF THE SKULL

J. A. KEARNEY, M.D.
Adjunct Professor of Ophthalmology, New York Polyclinic Medical School and Hospital
NEW YORK

A rise in the intracranial pressure above normal as the result of cerebral hemorrhage or edema is usually one of the most damaging factors in cases of recent fracture of the skull.

While it is interesting to know the nature and extent of the fracture revealed by the roentgenograms, it is not as important from the standpoint of immediate treatment as the determination of an increased intracranial pressure, and this is frequently foreshadowed quite early by edematous changes noted in the fundus of the eye.

In three patients of the series studied, roentgenoscopy revealed a distinct fracture of the base of the skull with no signs or symptoms developing other than those following an ordinary concussion. Some of the cases of basal fracture, in which an extensive hemorrhage occurred from the ear at the time of injury (virtually a "natural" decompression), developed none of the signs or symptoms of an increased intracranial pressure.

Observations were made in 212 cases that were diagnosed as fracture of the skull in the service of Prof. William Sharpe, at the New York Polyclinic, with whom I have studied the eye-grounds in these cases for the past two and one half years.

When the recent cases are examined for the first time, that is, within twenty-four hours after admission to the hospital, there is usually found a general edema blurring equally all the details in the fundus of the eye, and this blurring may be slight, or sufficient to obscure greatly the usual landmarks. The venous twigs when visible are usually dilated out of proportion to the size of the accompanying arteries.

Frequent and careful observations are made while these patients are in bed. In cases uncomplicated by an increase in the intracranial tension, the retinal edema gradually subsides. Occasionally, in some of the routine examinations after the first twenty-four hours following the accident, we note either an increase in the general edema that previously existed, or, to the edema that heretofore blurred equally all details, there is a decided added edematous obscuration of the nasal half of the disk and its margins.

These observations are most valuable, because they are usually some of the earliest indications of a rise in the intracranial pressure, and just as soon as possible after their detection the measurement of the pressure of the cerebrospinal fluid at lumbar puncture by the spinal mercurial manometer is done to determine its extent. In nearly every such instance an increase in the pressure of the cerebrospinal fluid above normal was recorded.

Infrequently there is seen in some of the cases an edema occupying the entire disk the height of which is measurable with the ophthalmoscope (papilledema). In all of these cases the cerebrospinal fluid was found to be under higher tension than normal

The degree of pressure of the cerebrospinal fluid at lumbar puncture recorded in a given case, and its pressure effect on the cerebral cortex, are prime factors which must be taken into account in deciding the character of the treatment the condition requires.

Dr. Sharpe advises that all patients with fracture of the skull be placed in bed, kept absolutely quiet, free catharsis maintained, given a liquid diet, and an ice helmet applied to the head. If no signs of intracranial pressure develop, the foregoing treatment is all that is given; but if the intracranial pressure is slightly increased and up to nearly double the normal, then in selected cases repeated lumbar puncture may be performed, and the condition relieved. If, however, the cerebrospinal fluid is found both with the ophthalmoscope and at lumbar puncture to be double the normal and even more than double, and the pulse rate may or may not be greatly lowered from medullary compression, then he advises a simple cranial decompression to be performed for the relief of pressure and for drainage before a possible collapse of the medulla occurs.

An examination of the fundus of the eye twenty-four hours after a lumbar puncture or cranial decompression has been done usually reveals a reduction in the amount of the edema that had existed previous to these operations.

127 West Fifty-Eighth Street.

SYPHILIS OF BLADDER *

H. A. FOWLER, M.D.
WASHINGTON, D. C.

Syphilitic disease of the bladder has been considered a rare affection. In the older textbooks it is sometimes not mentioned at all or it is dismissed briefly or its existence is even denied. In the most recent works the disease is considered so rare as to merit only the briefest mention. Within the past sixteen years, however, a considerable number of carefully studied cases have been recorded in widely scattered reports. These furnish sufficient data for a fairly comprehensive clinical study.

The history of this affection falls naturally into three periods. The first comprises those rare observations on syphilitics coming to necropsy in whom ulcers, tumors, or perforations of the bladder were discovered and were considered syphilitic in origin. This period extends to 1879, when Proksch critically reviewed all the published cases up to that time. He found only six cases which could be considered definitely proved (Morgagni, Ricord [two cases], Virchow, Vidal di Cassis, Tarnowsky).

To the second period belongs a small number of cases observed clinically in which the diagnosis was confirmed by the disappearance of all symptoms following antisyphilitic treatment (Morris, Grivtsoff [two cases], Chezelitzer, Margoulies, Towbien). No direct examination of the bladder lesion was made.

The third period begins in 1900, when Matzenauer published the report of his case and described for the first time the cystoscopic appearance of tertiary syphilis of the bladder. During the past sixteen years the number of observations has rapidly increased, so that up to the present time about forty cases have been reported. In 1909 it was shown that the bladder is

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

involved in the secondary stage. According to Levy Bing, a systematic examination of the bladder during the secondary stage of the disease will reveal that a more or less characteristic erythema, resembling the roseolar rash on the skin, and also superficial ulcerations are not rare. As these produce few or no symptoms they may be easily overlooked without a routine cystoscopic examination.

REPORT OF CASE

History.—N. G., boy, aged 19 years, came to the clinic complaining of frequent and painful urination, and passing bloody urine. His past history was unimportant. There was no history of syphilis or gonorrhea. For the previous three months the patient had had to pass urine frequently, night and day. On an average he got up eight times at night to void, and he urinated every ten minutes during the day. Marked pain in the perineum and along the urethra accompanied each urination, and the pain persisted several minutes after the act. At times the urine was quite bloody; at other times it was only slightly tinged with blood.

Examination.—The patient was a healthy looking young colored farmer boy presenting the facies characteristic of a painful urinary disorder. The chest and abdomen were negative. The external genitalia were normal. The urine was uniformly turbid, owing to the presence of pus, bacteria and red cells. It was slightly acid in reaction, and the specific gravity was normal. There was a slight cloud of albumin, but there were no casts. There were no scars on the penis or other evidences of healed cutaneous lesions. The inguinal axillary and epitrochlear glands were definitely enlarged. This glandular enlargement without apparent cause aroused suspicions of syphilis, and suggested the possibility of a syphilitic infection of the bladder. A Wassermann test was made and reported as strongly positive.

Cystoscopic Examination.—This was painful despite the free use of cocain. There was a marked general cystitis. All markings of the vesical mucosa were completely obscured. The mucous membrane was of a uniform rose color and had the appearance of a curtain of uniform color spread out over the inner wall of the bladder. It was difficult to locate the ureteral openings. Just to the outer side of the right ureteral opening was a single small ulcer, which was bleeding. It was about 1 cm. in diameter, with an irregular outline and an inflamed base. No other ulcers could be seen. The appearance of the ulcer suggested tuberculosis, but no tubercles could be found in the bladder, and the urine was negative for tubercle bacilli on repeated search.

Treatment and Result.—It was decided to apply the therapeutic test without any other form of treatment whatever, either local or general. Salvarsan, 0.6 gm., was given intravenously. The following day the patient noticed a definite decrease in frequency of urination. The improvement was continuous and rapid, and in a week's time the patient was able to retain the urine for three hours with little or no pain on urinating. A second injection of salvarsan was given, followed by mercury by mouth. Cystoscopy three weeks later revealed a remarkable change in the bladder. No trace of the ulcer could now be found. The ureteral openings appeared normal. The peculiar appearance of the mucosa had entirely changed. Normal markings of the mucous membrane were now clearly distinguished, with here and there discrete patches of inflammation such as one sees in an ordinary cystitis of a mild degree. No local treatment had been given previous to this examination. The urine was still turbid, owing to the presence of bacteria, pus cells and an occasional red cell. The improvement in the patient's condition was most striking. He was now able to retain his urine for three or four hours without discomfort, and voided without the marked pain and tenesmus of which he complained when he came under observation. His condition was so satisfactory that he insisted on going home to work, as he declared he was perfectly well.

COMMENT

There are several points of interest in the foregoing case report. The symptoms were those of a severe cystitis coming on without apparent cause. The urine showed an acid total pyuria, together with red cells and bacteria. The condition suggested tuberculosis of the urinary tract with a secondary infection, probably colon bacillus. Repeated search for tubercle bacilli, however, was negative. There were no changes to be made out in the epididymides, vesicles or prostate.

It so happened that I was looking for a case of syphilis of the bladder at the time. The general glandular enlargement aroused my suspicions of syphilis, and these were strengthened by a strongly positive Wassermann test. Cystoscopy revealed, in addition to a solitary ulcer about the right ureteral opening, a peculiar appearance of the mucous membrane such as I had never seen before. But there was nothing about the cystoscopic findings which I could consider characteristic of syphilis. Certainly the ulcer might easily have been mistaken for tuberculosis. I could not, as a result of my examination, say that the bladder lesion was syphilitic. It was determined, therefore, to put the patient on antisyphilitic treatment and to watch the effect of this on the symptoms and the vesical lesion. I was careful to avoid any local treatment whatever, or any internal medicine to relieve the symptoms. The marked and prompt improvement in the symptoms and the ultimate disappearance of the vesical lesion following salvarsan alone seems to justify the diagnosis of syphilis. It is of interest to note that no history of syphilis was obtained in my patient. This only serves to emphasize the point to which attention has so often been called, namely, that the history in many of these cases is thoroughly unreliable.

ETIOLOGY

Lesions of the bladder occur during the secondary and tertiary periods of the disease. In the parasyphilitic diseases the bladder is commonly involved, notably in tabes. Age and sex have no influence on the development of the bladder lesions. As tabes occurs more frequently in males, however, the associated bladder disturbance is more often observed in this sex. Although more common in middle life, cases occurring at the two extremes have been observed: at 4 years (Tarnowsky) and at 66 years (Gayet and Favre[1]).

The secondary lesions usually appear within a few months after infection, and are generally accompanied by lesions of the skin and other organs. Tertiary lesions, on the contrary, appear after a much longer period, up to twenty-five years. The bladder lesion may be the only evidence of the disease. In other cases the active syphilitic lesions of other organs or healed scars may be found. The majority of cases so far recorded belong to the tertiary period. It is quite probable that involvement of the bladder during the secondary stage would be observed more frequently if a routine cystoscopic examination were made. The occurrence of mild symptoms of cystitis during this stage is easily overlooked. These are attributed to the usual causes and their relation to a specific infection is not considered, particularly as they disappear under salvarsan and mercury.

---

[1] Gayet and Favre: Jour. de Urol., 1915, 6, 352, three illustrations in color.

SECONDARY SYPHILIS

Nine cases of secondary syphilis of the bladder have been reported — six males and three females. The youngest was a child, aged 4 years, having been infected by its nurse. At necropsy extensive ulcerations of the mucous membranes, including bladder and urethra, were found. The liver was syphilitic. In all cases the bladder lesions were accompanied by secondary syphilis elsewhere — skin, mucous membranes, etc. Macules, papules and ulcerations have been described. Duroeux has described a macular eruption resembling roseola of the skin. In Fenwick's case (postmortem), papules were disseminated over the bladder mucosa resembling condylomas. The ulcers are usually multiple, from two to twelve, rounded or oval, superficial, with a slightly elevated edge and a necrotic base. They occur more frequently about the ureteral orifices, but may be found in other parts of the bladder. The adjacent mucosa is edematous, hyperemic, and the vessels are injected and prominent. The remainder of the bladder appears normal.

The symptoms of the secondary stage vary with the location and character of the lesion. In the case of Levy Bing there were absolutely no symptoms referable to the bladder, and the vesical lesions were discovered during routine cystoscopy. With ulceration at or near the vesical neck, symptoms of cystitis more or less acute are observed. Frequency, urgency, and tenesmus may be marked day and night, and are not influenced by rest. Pain is then a constant symptom referred to the suprapubic area or perineum, and radiating along the urethra, to the rectum and to the lumbar region. Hematuria when present is never profuse and is always terminal. The bladder capacity is reduced, and varies with the intensity of the symptoms.

The urine is often clear. In the presence of infection it is turbid, owing to the presence of pus and organisms. It may be bloody from the presence of red blood cells. The presence in the urine of the spirochete has been reported, but this observation has not been confirmed.

TERTIARY SYPHILIS

By far the greater number of cases of bladder syphilis so far observed belong to the tertiary stage of the disease. This may be due to the more pronounced symptoms associated with tertiary vesical lesions. Attention is thus directed to the bladder, and examination reveals the specific nature of the trouble.

Gummas of the bladder develop insidiously like all new growths, and in the early stages produce little or no disturbance. Urination is slightly more frequent and associated with mild discomfort in the region of the bladder, in the perineum, or in the urethra. Hemorrhage, sudden in onset and profuse, may be the first and only symptom noted. More often symptoms of cystitis develop and increase rapidly in intensity.

Hematuria is the most constant and most striking symptom of tertiary bladder syphilis. It closely resembles the hemorrhage of new growth of the bladder. It appears suddenly without pain, and is uninfluenced by rest or posture. It may continue for days or weeks and gradually subside, only to recur after a longer or shorter period. Complete retention may result from the formation of clots within the bladder. As a rule, hematuria increases with the duration and progress of the disease. Exceptionally it may be absent altogether.[2]

Pain is an inconstant symptom, and varies with the location of the lesion and the presence or absence of infection as a complication. In Simons'[3] case the patient complained of a dull dragging pain in the hypogastrium which had existed for two years. At first intermittent, it became constant day and night, and increased as the bladder filled. In some cases, pain is a marked feature of the clinical picture. It is likely to be more severe at the end of urination if the ulceration is located at the bladder outlet, and it is accompanied by violent tenesmus. Frequency of urination is a disturbing symptom in most cases. Slight at first, it rapidly increases until the patient voids every few minutes with pain and tenesmus. While the symptoms in advanced, long standing cases are very severe and distressing, the absence of marked symptoms in the presence of severe bladder lesions in the earlier stages is noteworthy. The development of the more acute symptoms probably coincides with the degenerative changes in the gummas, and ulcer formation. Often the bladder lesion is the only evidence of syphilis to be discovered. In the absence of a definite history, the specific nature of the disease is not suspected.

CYSTOSCOPIC APPEARANCES

As viewed by the cystoscope, two varieties of lesions occur: gummatous ulcerations and papillomatous growths. The former are more common; the latter are rare. They occur separately, but may exist together.

Such ulcers are formed by the breaking down of a gumma of the bladder at its center. They are usually multiple, there being one to three which are rounded or oval, and which vary in size, the largest being from 1.5 to 2 cm. in diameter. They are elevated above the bladder wall, projecting into the bladder cavity. They present a punched-out appearance with irregular borders and a grayish necrotic base. On the base of the ulcer one sometimes observes the necrotic material detached in places, leaving a red, nodular surface which bleeds freely. The surrounding mucous membrane is edematous, hyperemic and dark red or livid in color. The vessels are markedly injected and prominent.

The papillomatous lesions are very rare. In Margoulies' case (Case 1) there were three small growths the size of a small bean situated close together and located on the base of the bladder just outside the ureteral orifice. The appearance of these growths suggested cancer of the bladder, and an operation was advised. It was by mere accident that the operation was not performed, and iodid was administered. Prompt disappearance of the lesions followed.

Gayet and Favre[1] report a case (Obs. 2) of sclerogumma of the bladder and prostatic urethra. The bas-fond was elevated, thickened and reddened, and indurated. The fiery red surface presented a few small ulcers and numerous fissures giving the appearance of cerebral convolutions. The general appearance resembled that seen in cancer of the cervix which has involved the bladder wall. The same character of lesion is described by Picot.[4]

Syphilitic lesions of the bladder, both secondary and tertiary, develop slowly and show no tendency to heal spontaneously. The long duration of symptoms in the reported cases is a striking feature of the clinical history. The secondary lesions are superficial. The tertiary involve the deeper layers of the bladder wall, and unless arrested may result in perforation. Such perforation, developing rapidly and involving the peritoneal surface, may terminate in fatal peritonitis. If the process develops more slowly, a loop of bowel may become adherent to the bladder, and perforation into the bowel occurs. Thus syphilis is one of the etiologic factors in the production of vesico-intestinal fistula. Vesicorectal or vesicovaginal fistula may result from the perforation of the bladder base.

TREATMENT

A striking feature of bladder syphilis is its prompt response to specific treatment. This is characterized by the immediate subsidence of all symptoms and the gradual disappearance of the vesical lesions. On the other hand, the measures usually employed in the treatment of ordinary cystitis have no influence whatever on either the symptoms or the lesions.

Profuse and persistent hematuria, which is often the presenting and predominant symptom, quickly subsides and disappears completely in a few days after the beginning of treatment with mercury or after the administration of salvarsan. No less striking is the prompt subsidence of all signs of vesical irritation, frequency, urgency, tenesmus, and a gradual return of the vesical capacity to normal.

The gradual healing of syphilitic lesions of the bladder may be followed by repeated cystoscopy. At the second congress of German urologists, Ernst Frank presented a series of cystoscopic photographs demonstrating the gradual healing and final disappearance of these lesions under treatment. Similar demonstrations have been made since by other observers.

It is the strikingly rapid subsidence of symptoms under specific treatment that makes the therapeutic test so valuable in differentiating syphilitic from nonsyphilitic vesical lesions.

The bladder changes occurring in certain diseases of the nervous system which we now designate as parasyphilitic are too well known to demand discussion at this time. They have been considered in another place.[5]

1621 Connecticut Avenue.

ABSTRACT OF DISCUSSION

Dr. Martin Krotoszyner, San Francisco: I have seen one case that, judging from the therapeutic result, I feel justified in classing among the cases that are considered syphilis of the bladder. A baker of 60 entered the hospital on account of sudden, painless and abundant hematuria, as the cause of which a small papillomatous growth, situated near the trigon and midway between the ureters, was ascertained cystoscopically. The patient admitted previous syphilitic infection. He had married late in life and was the father of two half-grown, healthy girls. Suspicious scars and other skin manifestations were the only other objective findings. The Wassermann was strongly positive. All bladder symptoms, including hematuria, quickly disappeared under combined antisyphilitic treatment. At a second cystoscopy, six months after the patient's discharge, the papillomatous excrescence was still visible, though apparently less prominent and reduced in size.

While I have observed a great many bladder lesions due to central or spinal syphilis, I have never seen a bladder ulcer the syphilitic nature of which, as in the case reported by Dr. Fowler, became obvious through its prompt reaction to specific treatment. My own observation, therefore, does not constitute a classical case of bladder syphilis. Such cases must be very rare indeed, and I recall in this connection the statement of Casper, who doubts the occurrence of bladder syphilis, of which he, like other authorities, has never been able to obtain authenticated cystoscopic evidence.

Dr. Charles J. Watterston, Birmingham, Ala.: I can add one more case to Dr. Fowler's series. It is the case of a negro girl in whom we made a cystoscopic examination on account of hematuria. There was a small, raised ulcer about 1 cm. in diameter just below the right ureter and several smaller erosions running down toward the trigon. The patient had a strongly positive Wassermann, there were other evidences of syphilis, and the lesions healed completely under antisyphilitic treatment; that is, salvarsan intravenously, followed by mercury.

Dr. H. A. Fowler, Washington, D. C.: Formerly we were led to believe that syphilis of the bladder did not occur, or, if it did exist, was rare. The experience of competent observers during the past few years compels us to change this view, and we now believe that this disease is not so rare as it was thought to be. This is in line with our knowledge concerning syphilitic infection of other mucous membranes. It is probably our failure in diagnosis rather than the rarity of the lesion that is responsible for the prevailing opinion.

There are one or two points to emphasize. There are no characteristic cystoscopic appearances by which syphilitic lesions of the bladder can be recognized. The diagnosis cannot be made by cystoscopy alone. The lesion cannot be differentiated in all cases by its cystoscopic appearances from tuberculosis or new growths. There are a number of cases reported in which syphilis was mistaken for cancer. In the secondary stage the lesions are superficial and may produce no symptoms whatever. Hence they are easily overlooked.

After all, the essential point is to have in mind the possibility of syphilis of the bladder if we are to avoid errors in diagnosis. The mistake has been made of advising operation for a supposed new growth, then to see the lesion clear up rapidly under antisyphilitic treatment.

NINETEEN CASES OF TYPHOID FEVER DUE TO EATING TURKEY SALAD

POWHATAN S. SCHENCK, M.D.
Health Commissioner
NORFOLK, VA.

A reception was held at a local club by a number of women of Norfolk, June 26, 1917, about fifty guests being present. Among other articles of food served, there were several bowls of turkey salad. The turkeys were supplied from a cold storage plant, the celery came from Baltimore, the lettuce was bought in the open market, and the mayonnaise dressing was mixed at the club. The salad was prepared by a colored woman who has a local reputation as a cateress; she cooked the turkeys at home, carried them to the club, and prepared the salad there. Her assistants were three colored women and a colored man.

Mrs. W. and Mrs. R., two of the guests, assisted in serving the salad, ate portions of it, and both came down with typhoid fever fourteen days later.

Mrs. D., Mr. C., and Mr. T., also guests at the reception, ate salad and in sixteen days developed typhoid fever.

---

[5] Besides the citations in the text, these additional recent cases will be of interest:

A critical review of the literature is given by Paul Asch in connection with his paper in the Zeitschrift für Urologie, 1911, **5**, 504.

Pereshivkin: Ztschr. f. Urol., 1911, **5**, 732.

Mikhailoff: Ztschr. f. Urol., 1912, **6**, 215, two colored plates.

Mucharinsky: Ztschr. f. Urol., **6**, 376.

Pedersen, James: Med. Rec., New York, 1916, **90**, 235.

Baker, Theodore: Surg., Gynec. and Obst., **24**, 187.

Mr. W., who had typhoid fever ten years before, stated that he ate the salad that night and two weeks later he noticed an elevation of his temperature with symptoms of mild typhoid. He had a fever, lassitude, weakness, and the usual symptoms of typhoid, which continued for three weeks. He thought he had a mild form of the disease. He reported it himself and said that he was quite certain he had typhoid, as he recognized all the symptoms of his former attack. We did not enter the case, however, in our records.

After the reception, the women sent a bowl of the salad to an orphan asylum. At that time there were eight little girls in the institution. One, aged 6 years, having a delicate stomach, the matron did not give her any of the salad; another, aged 12, refused it; the other six girls, aged 8, 5, 14, 14, 15 and 6, respectively, ate more or less freely of the salad, and in from thirteen to sixteen days all came down with typhoid fever and are now, August 4, in the hospital.

E., one of the colored women who assisted in preparing the salad, ate some of it and gave portions to her two children. All three came down with typhoid; E. three days after the reception, and the children two weeks later. E. complained of being sick for two weeks prior to the reception. A brother of E. visited his sister the day after the reception. He was given a dish of the salad, and developed typhoid, July 10. Another colored woman, who assisted in preparing the salad, carried a portion home, gave some to her two children and also to two nephews; all four came down with typhoid.

We find that all of these persons came down with fever in from twelve to sixteen days after eating the salad, except E., who assisted the cateress in preparing and serving the salad. No other common factor figured in these cases; practically all the patients took milk from different dairies; 50 per cent. of them did not drink milk at all. We eliminated water, in view of the few cases, together with the fact that the Norfolk public water supply is analyzed and examined daily and is constantly treated with liquid chlorin. Moreover, investigation shows that there is no case of typhoid fever on the watershed.

Each of these persons ate the salad and came down at the expiration of the usual period of incubation, except E. Now, we find that E. was sick for two weeks prior to the night on which the salad was served, although she did not take to her bed, but did go to bed three days later, namely, June 30, with high fever and the usual symptoms of typhoid. Of course, if she had been infected from the salad, June 26, she would not have developed typhoid at this early period. It would appear that E. had typhoid for two weeks prior to June 26, the night of the reception, and may have infected that portion of the salad which she handled.

It would appear further, as a logical deduction, that that portion of the salad handled by E. was the last served at the table, and only a small number of the guests partook of it, and it was this portion that was left over and distributed to the asylum and carried home by the assistants, since it is obvious that if this portion had been served early on the table it would not have been left over for distribution. On the other hand, if this portion had been served freely to the guests and was infected, the personnel of the cases would of course have been entirely different and no doubt larger.

PSYCHOSES OTHER THAN PARETIC DEMENTIA IN SYPHILITIC INDIVIDUALS *

ALFRED GORDON, M.D.
PHILADELPHIA

The great multiplicity and variability of manifestations in syphilis of the nervous system is a well established fact, but the rôle of syphilis in mental affections, with the exception of paretic dementia, has been suspected only since 1879, when Fournier[1] expressed the following view: "While syphilitic insanity has not yet a distinct place in nosology, nevertheless, personally, I feel that syphilis is apt to create cerebral disorders which may be considered as undisputable forms of insanity." Since then the relationship of syphilis to psychoses as cause and effect has been studied by a few observers, but as yet no definite opinion can be formed. The importance of this problem cannot be overestimated. The present contribution, which concerns twenty-three cases kept under observation for a long time, will perhaps enable one to elucidate some features of this difficult problem. Before entering into a discussion of the causal relationship between syphilis and the mental manifestations, let us consider the entire series of cases in two separate groups. In the first group there were five cases associated with secondary manifestations of syphilitic infection. The second group consisted of eighteen cases of mental disorders in the tertiary period of syphilis.

REPORT OF CASES—GROUP I

Cases 1 and 2.—Two patients developed a slight fever, with the appearance of mucous patches in the mouth, and a delirious state. Although the fever was brought down to normal, the delirium continued for a period of ten days in one case and seven days in the other. The delirium in both cases was accompanied by visual hallucinations. Complete recovery followed in both cases. Two months later in one, and three months later in the other, a similar attack occurred and again it was preceded by fever, also by a gastro-intestinal disorder, insomnia and headache. The delirium developed rapidly in both cases, and complete recovery followed after vigorous mercurial treatment. Both patients were free from alcoholic or other intoxications.

Cases 3, 4 and 5.—The other three patients of the same group presented mental phenomena of a more prolonged character. Mental confusion was the predominant feature. Defects of orientation in space and time and amnesia were the other manifestations. One patient, for example, presented enlarged cervical and inguinal glands, muscular pain and persistent headache, four months after the initial infection. He began then to complain of pain in the throat. Several mucous patches were seen in the pharynx and on the tonsils. The temperature rose to 101 F. He became somewhat stuporous, replied to questions with considerable delay, placed his hand frequently on the head as if in pain, ceased to ask for food, and was decidedly confused. He had great difficulty in recognizing his own relatives, and succeeded only after looking at them for some time. He made errors in dates and places. He could not recall the names of his friends. He mistook one of his children for another. He did not know the number of his children, the date of his marriage, and a number of other important events in his life. Being a teacher of languages, and speaking French quite well, he now could not recall the meaning of ordinary words. Asked in

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

[1] Fournier: La syphilis cérébrale, Paris, 1879.

French how he felt or if he had headache, he was unable to grasp the meaning of the word "tête." He kept on repeating this word without understanding it, and when insisted on, he finally said that he did not understand it. At night he was sometimes slightly delirious and would attempt to get out of bed. During the day he was found several times as if conversing with some one. He then looked around him, and, after saying a few words, he would pause and then lower or raise the tone of his voice. He evidently had hallucinations. This condition continued for two weeks, during which time he received an intraspinal injection of neosalvarsanized serum followed by mercurial inunctions. Improvement was soon evident. Two weeks later he received another similar treatment, and the man made a gradual recovery at the end of eight weeks. Memory, orientation and mental attitude have all returned to normal. The enlargement of the glands remained unaltered, but the mucous patches healed promptly. The headache disappeared entirely.

In another case a man of 29, piano teacher, five months after the initial infection presented an acute pharyngitis accompanied by a slight elevation of temperature (99.3 F.). He rapidly developed mental hebetude. He was confused and disoriented, and his memory became cloudy. The entire condition lasted about two weeks, during which time he had one intraspinal injection of 0.9 gm. of neosalvarsanized serum. With the disappearance of the pharyngeal condition, the mental disorder also became normal.

To sum up, the five cases of the first group presented a symptomatology which we ordinarily find in toxi-infectious psychoses. A delirious or stuporous state is the chief manifestation. A confusional condition is almost always present. Hallucinations may or may not be present. What is particularly interesting and quite characteristic is the occurrence of the mental phenomena apropos of acute secondary manifestations. When the latter disappear, the former commence to improve, but they usually last longer than the somatic manifestations. Finally, it is noteworthy to observe that the specific treatment has a rapid and efficacious effect on the psychic and physical manifestations which, as already mentioned, run usually parallel. The entire picture of the mental status in the secondary period of syphilis is quite analogous to that frequently observed in infectious diseases and especially in alcoholic intoxication.

GROUP II

The second group comprises cases in which the mental disorder developed many years after the initial infection. Without entering at present into the possible relationship between the old syphilitic infection and the present psychic manifestations, let us first register the occurrence of these manifestations in individuals with a former history of syphilis. We have in this group eighteen cases, three of which developed in connection with a traumatism, subacute confusional states with all the characteristic features met with in the first group of cases, except for the fact that those phenomena were of a milder character. There were no hallucinations, but merely a state of mild confusion and incoherence; also a mild delirium in the evening. A slight degree of amnesia was present throughout the entire duration of the affection. One case presented the mental manifestations of Korsakoff's syndrome, except the polyneuritis. We find here anterograde and posterograde amnesia, confusion, disorientation and confabulation.

Case 6.—M. H., a laborer, aged 45, contracted syphilis at the age of 20. He is married and has two children. His wife has had three miscarriages. The Wassermann test is positive on the blood serum. There is no history of alcoholism. After a few days of very hard labor he began to complain of headache, which became very persistent. Soon somnolence made its appearance. The patient would fall asleep several times a day. A confusional element was associated with the amnesia. The patient was at first unable to recall acts or thoughts of his own, or of others, which occurred on the same day, but soon the amnesia concerned also past events. He was unable to realize the situation. He could not tell how long he was ill. At times he would not recognize surroundings. He could not tell the time of the week or of the year. At other times he would clear up and answer questions correctly. Pseudoreminiscences were striking. He would speak of persons whom he never met. He would speak of events that never occurred; as for example, one evening he told his nurse of participating in a ball given by the mayor of the city, saying that he danced the entire evening with a beautiful lady. A few days later he spoke of having crossed a bridge at moonlight and of having met "a very strange man who led him to a castle and then disappeared." This fantastic confabulation, together with the amnesia, was quite conspicuous, and if we add the periodic somnolence, the mental clinical picture of my patient will be complete. As to the somatic symptoms, the patellar tendon reflexes were exaggerated. The patient complained of headache. The disorder lasted six weeks, after which a mild degree of mental hebetude remained for two weeks. The recovery was complete. Thirteen months later a similar attack occurred which was milder in its individual symptoms and which lasted but three weeks. At no time was there any evidence of polyneuritis.

This observation is interesting for two reasons. First, it speaks against the exclusivism of the discoverer of this syndrome, Korsakoff, who believed that it can exist only in association with polyneuritis and only in cases of alcoholism. Some authors have already called attention to the existence of Korsakoff's syndrome without polyneuritis. Suffice it to mention the observation of Stransky[2] on tabes, in which Korsakoff's syndrome disappeared when the patient was placed on antisyphilitic treatment. Chaslin and Portocalis[3] reported a case of Korsakoff's psychosis, without polyneuritis, which came to necropsy. Stepanoff,[4] Raymond,[5] and Roemheld[6] speak of the occurrence of incomplete Korsakoff's psychosis, namely, without polyneuritis, in syphilis of the central nervous system. They all appear to be unanimous in the opinion that the psychosis is due to a syphilitic intoxication, although Roemheld believes that the increase of intracranial pressure in cerebral syphilis may be a contributory factor. The foregoing observation of my series seems to corroborate the view that the polyneuritic psychosis of Korsakoff is characteristic not only of alcoholic, but also of other toxi-infectious conditions, such as syphilis.

The other important fact brought out in my case, a fact which may be considered of some diagnostic value, is the association of somnolence with the other mental manifestations. Raymond, quoting Jolly, and Stepanoff, from his observations in Ziehen's clinic, both call special attention to the symptom "somnolence" which was present in their cases of cerebral syphilis with Korsakoff's syndrome. It appears, therefore, that this occurrence is frequent enough to be taken into consideration in differential diagnosis.

The remaining fourteen cases are distributed as follows: Six cases presented the clinical picture of manic-depressive psychosis; three cases were of the paranoid type; two cases were with involutional melancholia, and three cases presented cerebral syphilis of long standing with progressive dementia.

The six cases of manic-depressive psychosis present two distinct groups. In three of them auditory hallucinations were present through every one of the maniacal phases of the condition. In the other three cases there were no hallucinations. It is also interesting to observe that the specific treatment had a beneficial effect on the first group, but no effect whatever on the last group. All the six cases presented a positive Wassermann reaction on the blood serum. The fact that in all the six cases there were morbid hereditary elements, such as insanity, psychasthenia and epilepsy, deserves special mention. In the first three cases there were also personal morbid antecedents, such as an attack of chorea in childhood, irritable disposition, and prolonged periods of insomnia. It is also interesting to call attention to the fact that in the three hallucinatory cases there was a marked meningeal reaction during the maniacal phases revealed by a cytologic examination of the spinal fluid. The number of cells ranged between thirty-five and ninety, and were mostly of lymphocytic type. One of these cases is particularly interesting:

Case 7.—A man, aged 40, a watchmaker, contracted syphilis at the age of 22. He is married and has three children. One child has Little's disease, one is epileptic and the third is apparently normal, but pale and frail. His wife had three miscarriages. The patient had three attacks of chorea when a child. He was always considered peculiar and eccentric, and frequently suffered from insomnia. His father was alcoholic, and his mother, before her marriage, was confined to an institution for the insane for a period of eighteen months for some mental disorder. At the time of examination he presented no special neurologic symptoms, except exaggerated tendon reflexes with occasional disturbance in the power of controlling the sphincter of the bladder. The Wassermann test was strongly positive on the blood serum and spinal fluid. Up to the present illness, nothing abnormal was observed in the patient's behavior. He made a comfortable living, led a regular life, and did not use alcoholic beverages. His third child suddenly took sick and died from pneumonia. As this was the only normal child, its death threw the patient into such a state of despair that for forty-eight hours he could not sleep and did not partake of any food. He became depressed, and ceased to speak. When questioned, he answered after considerable delay. He was found frequently with tears in his eyes, and would moan, and complain of his fate. The condition lasted six days, after which the patient entered a state of great excitement. He was restless and impatient. He would discuss matters in a loud voice and disagree on any subject. He became quarrelsome, and would break and tear things that fell into his hands. Two days later he commenced to complain of annoying and disturbing sights, especially in the evening. He saw faces of a threatening character. He saw his child being tortured by other children. He saw women jumping into a river for the purpose of drowning. The patient showed no confusion, and answered questions clearly, but persisted in seeing vividly the sights which, he said, threw him into a state of uncontrollable restlessness. Soon he developed expansive ideas of himself. He assumed an air of importance. He asserted his ability to accomplish acts that others could not. He considered himself well known to personages of note. He expected to become very wealthy. Gradually the period of excitement began to subside, the patient commenced to sleep at night, and the hallucinations disappeared. For two weeks the patient appeared to be free from any disorder and to take an interest in his surrounding, but he began to return gradually to his depressive state, which was of the same character as the first attack. With this attack, however, there was present a delusion of self-blame. He conceived the idea that his child died through his neglect. He worried intensely, and was frequently seen in profuse tears. This phase lasted longer than the phase of depression in the first attack. He finally recovered, but soon entered into a hypomaniacal state. He become talkative, restless and irritable, but the state of exaltation was decidely less pronounced than in the first attack of the psychosis. The state of mind concerning his own importance did not exist this time. There was no more talk about his riches, his abilities, etc. He had also some visual hallucinations of a transient character, which occurred only at night. He would see for a few moments images of faces of dead relatives or of his child. The patient was treated intraspinally with neosalvarsanized serum. He had two injections during the two attacks and only during the maniacal phases. A marked reduction of the lymphocytosis in the spinal fluid followed the treatment, and this ran parallel with the decrease in the excitement and with the shortening of the maniacal phase. In the depressive phase no increase of the reduced lymphocytosis was observed, and there was no further decrease in the already obtained cytologic formula. The spinal fluid was found normal when examined several weeks after his last attack.

At first glance one is inclined to admit a certain relationship between the lymphocytosis and the manifestations of the psychosis. On the other hand, there is no proof that the lymphocytosis did not exist before the outbreak of the psychosis. The disappearance of the lymphocytes may have been due entirely to the treatment. The irritation of the spinal meninges which was evident here because of the lymphocytosis was evidently of syphilitic nature. In view of the parallel development of the psychosis and the meningeal reaction it is difficult to reject all relationship between the two. It is equally difficult to admit that the syphilitic toxins are liable to create such a typical psychosis as is also encountered in cases without a syphilitic infection. One must not forget that we are dealing here with an individual whose personal and hereditary antecedents were of a pathologic nature. We have here important predisposing elements which are so frequently observed in the psychosis under discussion. We have here also a powerful exciting factor, namely, the death of the patient's beloved child, and of the only normal child, while the other two defective children were a source of constant worry and anxiety to the patient. We have here, consequently, sufficient causative agents to influence the domain of affectivity, as well as that of intelligence. The latent psychopathic tendencies were evidently awakened here not only by the direct emotional incident (death of the beloved child), but also by an outbreak of syphilitic meningitis which, to a certain extent, brought in some modifications in the clinical picture of the manic-depressive psychosis. The modifications apparently consisted of the hallucinatory phenomena, which were present exclusively during the maniacal phases. The occurrence of lymphocytosis only during the phase of exaltation, but not of depression, finds its *raison d'être* when we attempt to connect the attack of syphilitic meningitis with the simultaneous onset of excitement accompanied by visual hallucinations. It is quite logical to assume that parallel with a spinal meningitis there exists a cortical meningeal irritation. The presence of hallucinations, and only during the manic phase, may serve perhaps as an important diagnostic element in considering manic-depressive psychosis in an averred syphilitic individual.

The three patients who presented hallucinatory elements are still under observation. Their Wassermann reaction still remains positive in spite of freedom from distinct outbreaks of manic and depressive states.

The other three cases of the same group presented no hallucinations. The individual phases of the psychosis were similar to those of the first group. In all the Wassermann tests on the blood were positive, but on the spinal fluid they were negative. There was a lymphocytosis, but of an exceedingly moderate degree. The number of cells ranged from ten to eighteen. In all three patients the only objective neurologic symptom was a more or less increased patellar tendon reflex. The first outbreak of the psychosis was precipitated in all three cases by some strong emotional event. They all received between two and three intraspinal treatments. Two improved and one was uninfluenced by the treatment. The improvement in the two was temporary, as shortly after the last injection the condition returned. It was apparent that in this subgroup of three cases there was less relationship between the potential syphilis and the psychosis than in the first subgroup.

The occurrence of manic-depressive psychosis in the tertiary period of syphilis is certainly a possibility, but as to their relationship definite conclusions cannot as yet be drawn. In the literature there are some records pointing to the coexistence of this psychosis with cerebral syphilis, but so far none of them, including those of Kraepelin, can, with any degree of certainty, solve the causal relationship between the two. Finckh[7] was among the first to describe periods of expansion alternating with periods of depression accompanied by hypochondriacal delusions of a more or less systematized nature. Westphal[8] describes three such cases. The most extensive study of syphilitic mental disorders which may resemble phases of manic-depressive psychosis was made by Plaut.[9] He saw maniacal states with intense agitation and expansive ideas, so that he acknowledged the great difficulty in differencing them from genuine mania. Other authors saw similar conditions in syphilitic individuals. Mosny and Barat[10] report a case of acute psychosis of the manic-depressive type with a meningeal reaction of syphilitic origin.

The diagnosis of the psychosis during the maniacal state sometimes presents great difficulty. Kraepelin lays special stress on this difficulty in differentiation from paresis. Ziehen[11] reports cases in which the diagnosis of paresis of the circular form was made, but which turned out to be in reality cases of cerebral syphilis. In his work he refers to a case of Hitzig in which, in addition to the alternative phases, the delusive ideas were of the dementia type as in paresis, but the evolution of the disease compelled him to abandon the diagnosis of paresis. In the differential diagnosis the physical signs of paresis, as well as the state of the spinal fluid, and the Wassermann test on the blood and on the spinal fluid will be of great assistance.

Another difficulty in differentiating paresis from other psychoses is encountered when the morbid condition is stationary. Gaupp[12] is of the opinion that when a case of suspected paresis remains stationary it is invariably not paresis, but cerebral syphilis. In the diagnosis of manic-depressive insanity in syphilitic individuals it is important to lay special emphasis on the occurrence of hallucinations. Kraepelin and Finckh[7] believe that the latter are pathognomonic of syphilis and that the alternating psychosis is syphilitic in nature. Saiz[13] is firmly of the opinion that syphilis per se is capable of causing a manic-depressive psychosis. Raymond and Janet[14] report a case of manic-depressive psychosis in a case of hereditary syphilis. The six cases reported by me can also be placed among those recorded by authors mentioned. Particularly interesting are the three cases in which hallucinations were present, and especially instructive is the parallelism between the latter and the cytologic formula of the spinal fluid.

As previously discussed, although the subject of the direct relationship of syphilis to the alternating psychosis is not definitely established, nevertheless there are strong presumptions in favor of such relationship, particularly in cases which present hallucinations.

An association of syphilis with mental manifestations of the paranoid type was observed in three cases of my series. They were all in young individuals. The onset, the histories of the patients prior to the final outbreak, the evolution of the manifestations and their character were all analogous to the dementia praecox group of the paranoid variety. Kraepelin and Plaut[9] observed a number of cases in which many years after the initial syphilitic infection symptoms developed which are frequently found in dementia paranoides. In spite of their efforts to trace symptoms which could be attached to syphilis, but not to dementia praecox, they apparently have not fully succeeded. In reading their records one fails to find pathognomonic features on the basis of which a special clinical picture could be constructed. In Plaut's cases, physical symptoms were present, and this circumstance according to him should enable one to differentiate from the dementia praecox with a constitutional basis. But in Kraepelin's cases, which in general presented clinical pictures similar to those of Plaut's cases, physical symptoms were totally absent. Both authors, however, observed a few manifestations which, in their onset, mode of development and course, present a picture somewhat different from that of the classical dementia paranoides. They call attention to the absence of gross disturbances of the personality of the will and of the attitude and demeanor. The delusions develop rapidly and they are poor in their contents. The hallucinations are chiefly of the auditory type. Orientation is good except for a few brief episodes of cloudy consciousness. There is present a certain amount of realization of the disease alongside of a pathologic indifference to surroundings. Sometimes in the course of the disease there may occur apoplectiform attacks such as we observe in cerebral syphilis. The condition runs a very slow course and gradually dementia sets in. Then catatonic manifestations appear.

Among all these symptoms Kraepelin lays special stress on the hallucinations, which, in the syphilitic cases are, according to him, unusually intense. One of his patients, a girl of 21, having all the symptoms of hereditary syphilis with a positive Wassermann reaction, presented a persecutory delusion with multiple hallucinations, especially of auditory character. A superficial glance at this description will lead one to believe that all the elements of genuine dementia praecox are present, but a more careful analysis will reveal that the resemblance is not profound.

[14] Raymond and Janet: Arch. de neurol., October, 1903, p. 355.

In dementia praecox, with a constitutional basis, the delusional phenomena are frankly absurd and are not the result of cerebral effort. There is no desire on the part of the patient to know exactly the causes of the persecutory ideas, which appear usually as a result of sudden, extravagant and incoherent ideas subservient frequently to various hallucinations. The loss of intellectual activity, the negativism, the impairment of affectivity, the loss of orientation, the loss of the will which is manifested in rigid movements, are all the fundamental features of the classical form. Finally the delusional ideas do not, in the least, alter the attitude of the patient, so that some of them forget entirely their delusions. They all terminate in a state of brutishness and total indifference to surroundings.

If a comparison is drawn between this picture and that occurring in cases with syphilis, the contrast is striking. One must admit from the records so far published that syphilis is capable of developing a syndrome resembling dementia praecox, but not actually identical with it, and that we are dealing here with a special form of cerebral syphilis. The three cases observed by me presented many features in common. The resemblance to the classical dementia praecox was merely a resemblance, but not an identity. Delusions of a persecutory character were present in all, but they were not of a persistent character. Hallucinations were auditory, visual and hypochondriacal in the same patient. They were conspicuous and persistent. Orientation was fair. The attitude and demeanor were in general fair. The patients took at times a certain amount of interest in the surroundings. It was evident that no gross disturbance of personality was present for a long time until three and four years later, when signs of dementia commenced to make their appearance. Moreover, two patients had on several occasions attacks of aphasia, which were all of a transient character. In only one case were physical symptoms present, namely, irregular and unequal pupils and difficult micturition. In all three patients the tendon reflexes were increased. Finally two of the patients showed improvement after several intraspinal injections of salvarsanized serum. The third case remained uninfluenced by the treatment. The history of the latter presents some interesting features.

Case 8.—J. B., a man, aged 29 years, had a chancre at the age of 18. He was a mechanician by trade and had always been energetic, but about a year ago he commenced to neglect his work, would sleep late and complained of feeling tired. He was very irritable. Soon he became somewhat indifferent as to whether he lost his position or not, and no amount of reasoning could arouse him to his obligations toward his family. Soon he was found suffering from insomnia. He would pace his room or would go out on the street and wander aimlessly in the middle of the night. On several occasions he disappeared for a few days. Questioned as to his whereabouts and as to the reason of his conduct, he could not give an adequate explanation. He was observed very frequently to burst out laughing without the least provocation. His mother happened to fall down the stairs and sustained a concussion of the brain. She was unconscious for many hours. The patient witnessed the accident, but manifested no grief. He remained impassive and indifferent. The next day, however, he inquired about his mother's condition and became quite solicitous. He advised keeping her warm and having a physician to treat her. This awakening of sympathy was not deep enough and lasted but a couple of hours. The condition of indolence and apathy to his surroundings and to himself soon returned. Rapidly he developed hallucinations. He was found frequently at night and sometimes during the day with his ear close to the wall listening attentively and frequently becoming agitated while listening. Suddenly he would jump away from his position and run to the other wall and assume a hostile and threatening attitude as if ready to meet an attack of an enemy. Sometimes he would speak loudly, using profane language, swearing and cursing, keeping up his aggressive position. Two weeks later he apparently developed visual, in addition to the auditory, hallucinations, as he was seen to run aggressively from one part of the house to the other. He soon developed delusive ideas. He accused his mother and sister, also the attendant, of conspiring against him, of sending some persons to torture him and to threaten him. All this was true, he said, because otherwise he would not have heard so persistently those voices day and night. In spite of his apparent preoccupation and concern about the voices, as soon as stranges would call and approach him he would fall again into a state of apathy and would hardly reply to questions asked. If at times he would answer, the replies would be utterly absurd. He would frequently be unable to recognize his own people or old friends. Soon he developed a great desire for writing. He remained in his room for hours and would write incessantly. While his papers showed considerable confusion, nevertheless some expressions denoted a tendency to think of things and events in an expansive manner. He frequently mentioned "hundreds of banks"; "rows of houses"; "the great personages of England"; "like Napoleon I," "to conquer a hemisphere"; "to convert the whole world." Frequently were found such expressions as: "I have just heard them say they will come again tonight and pull all the wires out of me." For many months the hallucinations predominated in the entire morbid picture. He was given two intraspinal treatments with neosalvarsanized serum at an interval of two weeks. His condition as regards the hallucinations had, at first, improved, in that these occurred less frequently and with less intensity. The general intelligence showed some amelioration. He commenced to show less disinterestedness when being addressed, and began to take the initiative in asking questions. However, the improvement did not continue long. The patient soon returned to his former mental condition. Moreover, from this time on, the enfeeblement became gradually deeper, and catatonic phenomena became manifest. Negativism, stereotyped acts and expressions, resistiveness, were all present. The delusive ideas were no more in existence. The hallucinations, however, persisted, but with less conspicuousness than formerly, probably because of the accentuation of the dementia.

In this, as well as in the two other cases of the group, we observe an improvement in the hallucinatory phenomena following the antisyphilitic treatment, also a prolonged improvement in the general mentality in two cases and only a brief amelioration in one case.

The problem before us is whether it is justifiable to consider as a nosologic entity a dementia praecox type of syphilitic origin, or can syphilis per se create such a syndrome? In my three cases I found some of the features emphasized by Kraepelin. I found the lack of depth in the delusional ideas. The latter were not obstinately persistent. The hallucinations were unusually persistent and most conspicuous. There was not a complete loss of affectivity throughout the entire course of the disease. The catatonic manifestations became manifest only toward the end in the last case and were totally absent in the other two cases. It seems, therefore, reasonable to contend that syphilis is capable of creating a *syndrome* resembling that of dementia praecox. On the other hand, the deviation in the typical manifestations, and in the course of the affection, leads one logically to admit another presumption, namely, that the persons thus affected are potential praecox men, who would have developed the disease in spite of syphilis but in whom the syphilitic infection introduced certain modifications such as emphasized by Kraepelin and observed in my cases. The latter contention appears to be most plausible by virtue of the fact that the clinical picture in such cases is not sufficiently typical of the classical dementia praecox on a constitutional basis.

Another type of cases in my series is seen in the group of involution melancholia. In both cases we find a number of symptoms characteristic of the disease under this title. The patients were middle-aged women and married. One had had five children, all of whom died while young of diseases difficult to determine from the histories given by relatives. The other patient had had four miscarriages and had one living child. Both gave positive Wassermann reactions on blood serum on two different occasions. The clinical pictures in both cases consisted of the usual depression with a state of anxiety, insomnia and anorexia. A state of self-blame in one case for not being sufficiently religious, in the other for masturbation in younger life, were the only delusional ideas. Both presented also marked auditory hallucinations; both heard the voice of the Lord saying they would pay severely for their sins and their families would suffer for the same reasons. The peculiar feature of the hallucinations lies in their transient but frequently repeated occurrence. For days at a time the hallucinations would be totally absent, and then would suddenly reappear, especially at night. They would then be accompanied by severe headache and a slight rise of temperature. A lumbar puncture during the hallucinatory periods would reveal a lymphocytosis of the spinal fluid, namely, twenty-five and forty cells in the respective cases. It was evident that the periodic hallucinatory condition with the headache was due to an acute meningeal reaction. Both patients had, respectively, two and three intraspinal injections of neosalvarsanized serum, and improved considerably. As the treatment could not be continued, the former condition returned in both cases. One patient eventually committed suicide, the other is at present in a state of dementia. At the onset of the disease both patients presented a mild state of depression, which, together with a positive Wassermann reaction, naturally led to the diagnosis of an oncoming paresis. Such was the opinion on one of the two cases as expressed by a competent neurologist. Subsequent events showed that at no time were there physical signs, neither was there present the mental deficit characteristic of paresis. The characteristic delusional ideas, together with the state of depression, which grew progressively deeper with the absence of dementia for a very long time, all spoke in favor of melancholia. As to the influence of syphilis, it seems to me highly plausible to assume the same position which was taken by me in discussing the paranoid group of cases, namely, that while the two syphilitic middle-aged women suffered from melancholia, nevertheless, it is difficult to associate the mental affection with syphilis as effect and cause. In all probability, syphilis acted here merely as a modifier of the typical course of melancholia. One cannot assert with any degree of definiteness that syphilis per se is capable of creating such a characteristic clinical picture as melancholia.

The last group of my series consists of three cases in which no characteristic symptom of the classical psychoses could be found. If we exclude the paranoid and manic-depressive cases which may or may not present forms of cerebral syphilis, the latter will embrace those cases in which there will be present a great variety of mental manifestations directly connected with and dependable on syphilitic infection. In spite of this multiplicity of symptoms, there are, however, certain special elements which are constantly present and which may be considered almost pathognomonic of cerebral syphilis during its tertiary period. They are a confusional state and a pseudodemented state. The latter is the most frequent of all. It is characterized either by a mental hebetude, stuporous attitude, amnesia, deficient orientation in time and space, or else by an expansive attitude, optimism, euphoria and a psychic overactivity, to such a degree that it may assume the appearance of absurdity and even childishness. Delusions may or may not be present in either of these states. Syphilis of the brain in its broadest form covers a number of affections in which there is an organic involvement of the cerebrum. Besides the mental distubances there may be also attacks of hemiplegia or monoplegia, of aphasia, or of epileptiform convulsions. They all present no special difficulty of recognition, especially if the blood serum or the spinal fluid gives a positive Wassermann or Lange reaction. The therapeutic test is also of great value, as considerable improvement is obtained from antisyphilitic treatment. Some diagnostic difficulty is observed in cases which present some of the manifestations of paresis, so that for a long time considerable hesitation is experienced in formulating a diagnosis and giving a prognosis. The following three cases may be briefly presented as an illustration of such a difficulty.

Case 9.—A woman of 39 who had three children living and had had four miscarriages was admitted with a very severe headache to the Douglass Hospital. The Wassermann test proved to be negative in the blood serum and positive in the spinal fluid. The cellular count was thirty-five. At first mentally clear, she gradually developed a depressive state, during which she spoke and acted in a very slow manner. Her replies to questions were much delayed and her memory, especially, became affected. She was unable to tell the number and names of her children, how long she had been in the hospital, or how long she had been married. She could not tell correctly the day of the week, the date or the year. She could, however, converse on the weather, could criticize correctly the food, the behavior of the nurses, etc. She was frequently seen muttering some words quietly as if she were conversing with some one. Evidently she had auditory hallucinations. While in the hospital she had two attacks of aphasia of brief duration, one lasting five and the other three days. Among the somatic symptoms the following may be mentioned: The pupils were unequal, but both reacted well to light; the patellar tendon reflexes were increased; the speech was somewhat hesitating. In the presence of such a symptomatology, paresis was the diagnosis first thought of. But the following essential elements spoke against paresis: While her affectivity was depressed, and in spite of the fact that she did not fully realize the gravity of her affection, she nevertheless appreciated the fact that she was ill, and frequently inquired about her discharge from the hospital. She obeyed all the orders of the nurse, and was quiet and undisturbing. There were no delusive ideas at any time. The speech disorder was not distinctly paretic, although it was somewhat hesitating. There was no tremor, and no ataxia was evident at any time. The intraspinal treatment with neosalvarsanized serum proved to be most beneficial. The improvement was very noticeable in the psychic sphere. Amnesia and orientation have greatly improved. She is still under observation, and at this date she has had five injections. The few somatic symptoms have entirely disappeared, namely, speech, pupils and increase of reflexes.

CASE 10.—A man, aged 41, with a history of syphilis contracted twenty years ago, was admitted to the Douglass Hospital. The Wassermann reaction was positive in the spinal fluid and in the blood serum. On admission he complained of insomnia and frontal headache, but had a smile on his face and a very cheerful countenance. In talking to him over his past life, one is struck by a slight confusion in his sentences. His memory is defective. He cannot recall the name of his last employer, for whom he worked several years; nor could he converse on important topics of the day. In giving dates he made gross mistakes. Asked how long he had been in the hospital, again he answered very inaccurately. What was particularly interesting was the ability of self-criticism. He realized that he was wrong, that he made mistakes, that there was something "wrong with him," to use his own expression. He often laughed at his answers, saying that he felt he was making errors, but he could not help it. At times he was unusually jovial, and spoke of great undertakings, of being on friendly terms with important personages, of being very happy and of wishing for nothing. At the same time he mentioned seeing spirits at night when he said his prayers, but those hallucinations occurred only occasionally. A somatic examination revealed increased knee-jerks, unequal pupils, but responding well to light and accommodation. At times there was nocturnal incontinence of urine. Treatment with neosalvarsanized serum gave prompt relief. After the second injection the confusional element disappeared, the amnesia improved greatly and the euphoria became less pronounced. He is still under observation at his home in another state, whence he sends me communications about his death. They are all free from incoherence and the ideas are expressed in a coordinate and logical manner.

In this case the entire picture of the affection suggested at first paresis, but the evolution of the symptoms, the absence for a long time of characteristic physical symptoms, the rapid improvement and especially the nature of the mental manifestations all were against the diagnosis of paretic dementia.

CONCLUSIONS

An analysis of the cases described in this study tends to show that while the mental disturbances, during the secondary stage of a syphilitic infection, could be considered with a great degree of certainty, as directly dependable on syphilitic toxins, the same degree of certainty cannot be entertained with regard to a direct relationship of psychosis developed during the tertiary period of syphilis. In the former, the mental manifestations are in all analogous to those which we observe in toxi-infectious states from any origin. The confusional and delirious conditions, as well as the hallucinations, ran parallel with secondary manifestations and with fever. When the latter disappeared the former commenced to improve. Besides, the antisyphilitic treatment had a very manifest and favorable effect on the mental phenomena. In the other series of cases we find various psychoses which developed many years after the initial infection and which in all respects presented the typical pictures of classical psychosis, such as Korsakoff's syndrome, manic-depressive insanity, melancholia and dementia paranoides. Great difficulty is encountered and no definite opinion can be formed with regard to a direct relationship between the psychoses and the infection which occurred many years previously. On the other hand, it has been observed that those psychoses in syphilitic individuals presented some modifications which could justly be attributed to the influence of syphilitic toxins. In the light of our present knowledge we are not warranted as yet to claim for syphilis the ability to create per se the well established forms of insanity which we observe without a syphilitic infection. The literature on the subject is very meager, and a considerably larger number of carefully collected records will be necessary to enable us to establish in a more definite way a causal relationship of syphilis to psychoses. For the present, no final claim can be made as to a type of mental disease characteristic of syphilis. On the other hand, from the observations which we possess we are not authorized to reject entirely the possibility of psychoses being the result of syphilis.

1812 Spruce Street.

ABSTRACT OF DISCUSSION

DR. E. E. MAYER, Pittsburgh: Does any one doubt that the same psychotic symptoms may be due to different causes, toxic, psychogenetic or inflammatory? Does any one doubt that a patient with paresis may have another type of psychosis also? Perhaps I did not follow Dr. Gordon's reasoning closely; however, it is always a mistake to establish a diagnosis if by doing so we ignore the possibility of another syndrome being present which is not directly due to the same causal agency. It is this faulty judgment which I gather Dr. Gordon is speaking against. But again, what psychiatrist does not know that his argument is true without it being necessary to cite a multiplicity of cases to prove it.

DR. C. R. WOODSON, St. Joseph, Mo.: There is a syphilitic condition unlike that of paresis in which patients who do not recover live many years. I remember cases twenty-five years ago, before the Wassermann reaction or salvarsan treatment were known. A man came under my observation confused and depressed, with symptoms of cerebral syphilis. I placed him on mercury and mercury inunctions, with 1,000 grains of potassium iodid daily for two or three months. He made a satisfactory recovery and remained well. I have seen him twice yearly for twenty-five years. One of our surgeons had a syphilitic patient who had not been treated vigorously. He came to the hospital with pronounced insomnia and in a maniacal condition. Large doses of iodids, 1,000 grains daily, with mercury were given, and he made a splendid recovery. Many patients come into the hospital with a positive Wassermann test, monoplegia and other symptoms of cerebral syphilis. In some atypical cases it is hard to diagnose a case of paresis from syphilis of the central nervous system. I do not believe paresis is curable. I have seen marked temporary improvement, followed by death from some intercurrent affection, or relapse and death from paresis.

DR. CHARLES R. BALL, St. Paul: It is difficult for the physician in dealing with syphilis to differentiate between symptoms due to syphilis and symptoms caused by other diseases which they may have and which have no connection with their syphilis. Because a patient has had syphilis is no reason for regarding him as immune to other diseases. A syphilitic is just as susceptible to a psychosis or neurosis, after having had syphilis, as he was before he had it, and perhaps more so, because the syphilis itself tends to make him more introspective. Dr. Gordon brings this point out clearly in his paper. We must be quick to distinguish in syphilitics those mental disturbances which are caused by syphilis and those which occur incidentally in connection with it. In making this distinction the serobiologic reaction will be found invaluable.

Recently I had a patient with a typical simple melancholia; fifteen years before he had suffered a similar attack; twelve years previously—three years after his melancholia—he contracted syphilis. The serobiologic reactions were all negative. In spite of this the patient insisted on connecting his syphilis with his present trouble. He would take no medicine whatever except mercury in some form. He finally left me to place himself under the care of some one who would administer mercury to him in heroic doses.

Dr. Alfred Gordon, Philadelphia: Syphilitic individuals, in spite of the syphilis, and not on account of it, may present symptoms resembling ordinary psychoses. They may present a picture of manic depressive psychosis, dementia praecox and others. The syphilitic patient may have all sorts of diseases, and when we do investigate for syphilis and the tests are positive we can improve the patient's condition. One often finds, on close observation, modifications of classical symptoms, and this is due to some modifying factor such as syphilis. I have no illusions as to the cure of syphilis of the central nervous system. I am not optimistic to that degree, but I am far from convinced that the last word has been spoken. I think we can often improve the condition. While my paper is largely technical, there is a practical side, namely, the findings of modifications in the typical clinical pictures and thereby a possibility for improvement by antisyphilitic remedies.

INTRAVENOUS GLUCOSE INJECTIONS IN SHOCK*

JOSEPH ERLANGER, M.D.
ST. LOUIS

AND

R. T. WOODYATT, M.D.
CHICAGO

In accordance with a prevailing opinion, the low blood pressure in "shock" is associated with a diminished effective volume of blood in the vessels, and the two factors constitute in themselves essential parts of the shock mechanism. On this assumption, benefits should result from procedures having the effect of holding water within the vessels. In normal individuals it is possible to accomplish this by effecting an entrance of glucose into the blood at appropriate rates sustained for sufficient lengths of time. Marked hydremic plethora and striking increases of the systolic blood pressure may thus be produced, and the present study has shown that the mean arterial pressure may also be elevated in this way. Glucose is, moreover, a food; it is capable of increasing the power of involuntary muscle contractions, elevating the total metabolism, combating at least one type of acidosis, and restoring depleted glycogen reserves. Has it a value in the treatment of cases of shock?

During the past two years, Woodyatt, with Sansum and Wilder, has studied the physiologic effects of sustained intravenous glucose injections at known rates, and applied the method to several clinical conditions, including two cases having features of shock. Favorable results in these cases made it appear desirable to study a longer series under conditions permitting more exact observations. This was not possible with the available clinical material, and it was decided to test the principles in cases of experimental shock in animals. Erlanger and his associates have during the summer performed some sixty experiments on shock in animals with special reference to the circulatory phenomena and the vasomotor mechanism. A large number of records for control purposes and a perfected technic were thus available. The primary purpose of the work here reported was to ascertain how the symptoms of experimental shock in dogs might be influenced by intravenous glucose therapy. Incidental observations were made on the effects of salt solutions, salt and carbonate solutions, and epinephrin. The work was done in eight days, and no attempt is made to give this report the character of a completed study. The possible differences between the conditions induced in dogs and that of shock in human cases is appreciated, as also the fact that the slow intravenous injection of glucose in postoperative conditions is not a new procedure.[1]

PHYSIOLOGIC PRINCIPLES

When a single dose of glucose is injected into a peripheral vein, there is a temporary increase of the total quantity of sugar in circulation. The injected sugar passes rapidly out of the blood into the tissues. During its stay in the vessels, the blood volume rises and a state of hydremic plethora develops, owing doubtless to the binding of water by the extra glucose in the vessels. This is shown by a fall in the hemoglobin percentage, and a coincident fall in the blood sugar percentage following an initial rise. These facts were demonstrated by Brasol[2] in 1884, and confirmed and amplified by Biedl and Kraus,[3] Starling,[4] Kleiner and Meltzer, and others. Similarly during the period of absorption following the alimentary administration of glucose there is at first a rise but later a return to the normal of the blood sugar percentage, and simultaneously with the latter a fall in the hemoglobin percentage.[5] In shock cases it is frequently impracticable to secure the entrance of glucose into the blood through the alimentary tract, nor is the subcutaneous injection of glucose a harmless clinical procedure. If glucose is injected into the peripheral venous blood of a normal resting (unanesthetized) individual at or below the rate of 0.8 to 0.9 gm. per kilogram of body weight per hour, the injection may be sustained in most cases for hours without causing glycosuria.[6] With injections of 0.9 gm. or more of glucose per kilogram per hour, glycosuria develops, and the rates of sugar excretion then bear definite relationships to the rates of injection. The higher the absolute injection rates, the higher the absolute rates of glycosuria.

During sustained intravenous injections at or below the tolerance rate, glucose passes from the blood into the tissues and there undergoes chemical change (polymerizations, oxidations, etc.) at the same rate as that of injection. There is no material accumulation of glucose itself in the tissues. Injections at subtolerant rates therefore have the effect of increasing the quantity of glucose in the blood without producing any considerable increase of the glucose in the tissues. The result is a disproportionate increase of the power of the blood to hold water, and a state of hydremic plethora develops and presumably persists as long as the injection is sustained. The water held by the blood must come from the tissues or from the injection site or both. If the water injected with the glucose is not sufficient to satisfy the glucose in the blood, some water will flow into the blood from the tissues. When the glucose injection is stopped and the last of the injected glucose passes into the tissues, the water previously held in the blood is to a large extent discharged suddenly into the urine. This whole phenomenon differs essentially from that obtainable with inorganic salt solutions, because such salts when injected also pass into the tissues, but when once there are not destroyed. There is therefore the possibility of salt accumulations in the tissues holding water there, and in part counteracting the effects of the salt in the blood stream.

With sustained intravenous glucose injections at rates higher than 0.8 to 0.9 gm. per kilogram per hour, the glucose utilization fails to keep pace with that of injection and the tendency is toward some accumulation of unchanged glucose. If the kidneys are functioning actively this glucose appears on the urinary side of the renal membrane and tends to collect water in this locality, probably for the same reason that glucose in the blood produces hydremia.[7] This tendency is expressed as polyuria. Now if the diuresis exceeds the rate of water administration, water will flow from the tissues to the blood and thence to the urine, and hydremia will be sustained, as long as the water supply is adequate. But if the kidneys do not function in this way, most of the unchanged fraction of the glucose injected remains in the body and tends to behave like a salt, causing accumulations of water in the tissues and body spaces wherever it may go. In shock cases the secretion of urine is likely to be impaired. Accordingly the most rational application of intravenous glucose injections in shock would appear *a priori* and on theoretical grounds to consist in long sustained uniform injections at subtolerant rates. Just what the tolerance limit will be in any pathologic condition cannot be stated. When the kidney function is impaired the rate of injection necessary to produce glycosuria cannot be used as a criterion. The most appropriate injection rate might be expected to lie within the normal tolerance limit at possibly 0.3 to 0.6 gm. of glucose per kilogram of body weight per hour. For a man weighing 50 kg. this would imply the injection of from 15 to 30 gm. of glucose per hour, corresponding to from 84 to 168 c.c. of 36 per cent. solution hourly, or twice these quantities of 18 per cent. solution. Although moderate accumulations of unchanged glucose in the body might do no harm or perhaps even prove desirable, it has been noted in the experiments on shock in dogs, produced by occluding the inferior cava, that a general hemorrhagic tendency supervenes when the administrations are excessive.

EXPERIMENTAL

The solutions injected consisted of chemically pure glucose in strengths of from 18 and 36 per cent., to which on occasions epinephrin was added, of 0.9 per cent. sodium chlorid, and of an alkaline saline solution, 0.3 per cent. anhydrous sodium carbonate in 1.4 per cent. sodium chlorid solution (Fischer's solution). Whenever possible the physiologic sodium chlorid solution was injected either just before or just after the glucose as a control to the direct volume effects of the latter. The injections were made centrally into the vena saphena at a practically constant rate by means of an apparatus devised by Woodyatt.[8] Continuous records were made of the pressure in the carotid artery by means of a mercury manometer. Dogs were used exclusively. They were anesthetized with ether. In some experiments the rate of secretion of urine was followed, a catheter being passed into the bladder for this purpose.

Only one experiment has been done on a normal animal. The glucose solution (36 per cent.) was injected for a period of thirty minutes at the rate of 0.8 c.c. per minute (1.78 gm. of glucose per kilogram per hour). The injection raised the arterial pressure, but not more than from 5 to 7 mm. of mercury. The pulse amplitude, however, increased quite appreciably, indicating the development of some plethora. The maximum effect seems to have been attained during the first five to ten minutes of the injection, and was maintained for ten or more minutes after completion of the injection. The slightness of the rise of the pressure in comparison with the considerableness of the increase in blood volume, indicated by the change in pulse amplitude, probably is to be attributed in part to a diminution in the viscosity of the blood, due to hydremia, and in part to vasomotor accommodation.

The animal was then bled to the extent of 150 c.c., and after the pressure had become constant, well below the normal level, glucose was again injected at the same rate, but for a period of twenty minutes. During the injection period the pressure rose from 107 to 120 mm. of mercury, and during the succeeding ten minutes it continued to rise, finally reaching 125 mm. of mercury. It then declined to 111 mm. of mercury in the course of the next thirty minutes. The pulse amplitude was increased. Salt solution injected at the same rate raised the pressure only 5 mm. of mercury, without appreciably changing the pulse amplitude.

It is inferred from this experiment that in normal animals the compensatory mechanism tends to hold the arterial pressure close to the normal level during the plethora determined by the glucose solution; but that when, as after hemorrhage, the efforts of a normal compensatory mechanism fail to hold the pressure up, the same hydremia results in a more marked rise of pressure.

The rate of injection employed in this experiment would lead in the unanesthetized dog to a glycosuria of some 0.5 gm. per 10 kg. per hour, and this would cease within fifteen minutes after the discontinuance of the injection. In this anesthetized animal, however, the injection caused a heavy long lasting glycosuria and a coincident hyperdiuresis of such a grade that in the course of the experiment more water was excreted by way of the kidneys than was injected into the circulation.

In six experiments the effect of the injection of glucose in different doses was followed after shock had been produced by temporary partial occlusion of the inferior vena cava.[9] Our previous experience with this method of inducing shock justifies the statement that when, after deocclusion of the cava, the arterial pressure eventually begins consistently to decline, this decline proceeds, almost invariably, without break until the animal dies, though the pressure at which the decline begins may be only 20 mm. of mercury below the normal level. Despite the fact that the arterial pressure rises quite appreciably with deocclusion, we are inclined to believe that the damage that has been done to the tissues during the period of occlusion is irreversible. That is to say, despite whatever may be done, the cells of the body eventually will fail to carry on the functions necessary to the life of the organism.

[9] Janeway and Jackson: Proc. Soc. Exper. Biol. and Med., 1915, **12**, 193.

In such an event, the only result that could be anticipated from any form of treatment would be but a temporary improvement of certain of the functions.

Our tests of the action of glucose were begun in that stage of the experiment in which the pressure begins consistently to fall. The persistence of heavy glycosuria in the normal but anesthetized dog for hours after a twenty minute injection at the rate of 1.8 gm. of glucose per kilogram per hour indicates that such a rate of infection in shocked animals which pass no urine must result in an accumulation of free sugar in the organism. The first intravenous dose at supertolerant rates must therefore give the clearest indications of what the injection of sugar is capable of accomplishing. In the table are collected the results of the first injections with the animals in shock. In evaluating the effect of the injections on the blood pressure, account must be taken of the fact that such changes as occur are built up on a pressure curve whose general tendency is to decline with time. In the construction of this table an attempt has been made to indicate this fact. For example, it is seen in the table that in Experiment 3, in which the greatest rise of pressure was recorded (from 55 to 100 mm. of mercury), the pressure at the start of the injection was practically stationary, presumably as a result of the action of salt solution injected immediately preceding the sugar injection; while Experiment 5, in which the smallest rise was recorded (from 72 to 76), was one in which the arterial pressure was falling quite rapidly at the time the glucose injection was started. The other pressure increases ranged between these extremes. On account of the difficulties just mentioned, the determination of the duration of the sugar effect on the pressure is not a simple matter. In at least two cases the maximum pressure is attained some time after the cessation of injection; and whereas in some of the other cases the maximum pressure is attained during the period of injection, the pressure curves are of such a form as to indicate that the effect is manifesting itself not alone during the whole of the injection period, but for some time subsequently.

RESULTS OF THE FIRST INJECTION WITH THE ANIMALS IN SHOCK

Experiment Number	Normal Mean Carotid Pressure	Pressure at Time of Injection[*]	Injection Period, Min.	Pressure Rise		Pulse Amplitude Increases		Dosage				Action Subsequent to Injection	Remarks
				To Mm. Hg	In Min.	From Mm.	To Mm.	Per Kg. per Hour, Gm.	Percentage Solution	Rate of Injection, C.c. per Min.	Injection Period, Min.		
1	159	51 and falling	73.	60	45	1.5	3.0	0.57	18	1.0	73	The pressure is falling during the last 20 minutes of injection	Sugar injected immediately after salt solution, which had kept the pressure constant
2	140	64 and falling	68	96	68	3.5	4.5	3.7	36	1.85	68	Pressure immediately falls slowly, and, after 10 minutes, rapidly	Sugar injected immediately after salt solution, which had failed to maintain the pressure
3	117	55 and stationary	25	100++	45++	4.0	5.5	3.6	36	2.0	25	It would appear as though this animal was coming out of shock; the rise of pressure stopped only when the cava was again occluded	Immediately after 20 minutes salt injection which raised pressure 4 mm.
4	195	61 and falling	25	70	[†]	5.0	8.0+	2.2	36	1.0	25	....	A previous salt injection had temporarily raised the arterial pressure 4 mm. Hg
5	142	72 and falling quite rapidly	23	76	14	6.0	6.5	3.0	36	2.0	23	....	Pressure can be raised only by epinephrin despite the considerable increase in pulse amplitude by subsequent sugar injections
6	110	66 and falling	30	88	35	4.0	7.0+	4.0	36	2.0	30	Pressure falls rapidly after 5 minutes elapse	
8	122	78 and falling rapidly [‡]	25	86	45	5.0	8.0+	3.7	36	2.0	25	Pressure falls rapidly	

[*] The pressure usually is uninfluenced by the sugar injection until from five to ten minutes have elapsed. This is the pressure at the moment the injection begins to cause the arterial pressure to rise.

[†] This was immediately followed with a stronger solution of sugar for seventeen minutes by which the pressure was raised only to 62 mm. Hg. Then epinephrin was added to the sugar. This raised the arterial pressure to 97 mm. Hg; but when the epinephrin was withdrawn, while the *sugar injection* was continued, the pressure fell in the course of twenty-nine minutes from 97 to 49 *mm.* Hg.

[‡] Salt solution for twenty-five minutes did not appreciably modify the pressure curve. Ten minutes later, while the pressure was *rapidly* falling, sugar injection was begun. The pressure continued to fall but at a decreasing rate, and had just begun to rise at the end of the twenty-five minute period of sugar injection. As indicated, it continued to rise for twenty minutes.

The table also shows the effect of the sugar injection on the pulse amplitude. This is invariably increased by the injections, and the persistence of the sugar effect is brought out more clearly by the changes in pulse amplitude than by the changes in pressure. Thus in Experiment 6, whereas the mean pressure begins to fall five minutes after the cessation of injection, and in thirty minutes has returned to its previous level, the pulse amplitude at that time has not nearly declined to its previous value. This greater persistence of the effect on the pulse amplitude than that on the arterial pressure is seen best, however, after the second and third injections.

The dosage of glucose has ranged between the extremes of 0.57 gm. per kilogram per hour and 4 gm. per kilogram per hour, that is to say, between a so-called subtolerant dose and one five times exceeding the tolerant dose. All injections resulted in a rise of pressure, which invariably was much greater than that caused by the control injection of salt solution, which often, indeed, gave an inappreciable response. Owing, however, to the difficulties mentioned, it would take a much larger series of experiments than we have performed to determine the optimum dose of glucose.

After a beginning has been made in the induction of shock by occlusion of the cava, urine secretion ceases despite the injection of sugar in doses which, in the normal animal, cause a marked diuresis. Urine was not secreted even when the alkaline hypertonic salt solution was injected.

A few tests have been made, but usually quite late in the course of the experiments, of the effect on the arterial pressure of injecting an alkaline saline solution. These tests were made only casually, and no hard and fast conclusions can be drawn from them. So far as we have gone, however, at the rate of injection employed, no obvious effects could be discerned.

We also have occasionally combined epinephrin, in concentrations ranging from 1:100,000 up to 1:25,000, with the glucose solutions. These injections also have been made late in shock. While they raised the pressure further, and possibly increased the pulse amplitude more, than the injection of simple glucose solutions, their effect was very transient and they seemed to leave the pressure at a lower level than it would have reached in the same time if nothing had been injected.

In only one case have we succeeded by the injection of sugar in turning a falling pressure into a rising pressure tending to attain the normal level. The animal in which this occurred was particularly resistant to the effects of occlusion of the cava. Whereas a two-hour partial occlusion of the cava in our experience ordinarily suffices on deocclusion to leave the arterial pressure well below the normal level, and to start the pressure on a downward course within forty or fifty minutes, in this case the arterial pressure returned to the normal level after deocclusion within twenty-five minutes. After a second period of occlusion lasting forty-five minutes, the arterial pressure was still rising fifty-five minutes after deocclusion. The same was true after a third period of occlusion. It was only after the fourth period of occlusion, which lasted one and three-quarter hours, that the arterial pressure after deocclusion started on a downward course. It was then, after a preliminary test injection of saline which held the pressure practically level, that the sugar was injected. The pressure rose from 55 to 90 mm. of mercury during the injection period of twenty-five minutes, and continued to rise in the after-period, finally reaching 100 mm. of mercury, and it was still rising when, as it was believed that the animal had recovered from shock, the cava was again clamped in order again to reduce the animal to shock.

Previous experience in the production of shock indicates that when it is induced by temporary partial occlusion of the inferior vena cava, vasomotor tone, in the stage in which we have made the first sugar injections, is either below normal or at the lower limit of normal. In order to determine whether or not the difficulty in obtaining lasting improvement as a result of the injection of sugar is attributable to the damaged state of the vasomotor mechanism, in one experiment the effect of sugar injection has been tested in shock produced by temporary partial occlusion of the descending aorta. In shock thus produced, we judge from experience that the vasomotor tone, at the stage with which we are now concerned, is either normal or above normal. The experiment ran quite smoothly; but here again the action of the sugar, while quite distinct, was as ephemeral as in the majority of our experiments.

In this experiment, urine secretion stopped shortly after the aorta had been clamped, and none was formed until about two hours had elapsed after deocclusion, when, apparently under the stimulus of the sugar injection, 1 c.c. was passed. This is the only instance in which urine was formed after the production of shock in this series of experiments. Macroscopically the urine did not contain blood.

One of the most interesting phenomena brought to light by this series of experiments, and seen best after several injections have been made, is a decline of the pressure, subsequent to the injection, to a level well below that obtained previous to the injection, despite a pulse amplitude which is higher under the low pressure after the injection than it was under the higher pressure preceding the injection. The increased pulse amplitude undoubtedly is a measure of the increase in blood volume. Presumably, therefore, the pressure is lower after than before the injection, despite an increase in blood volume. This condition probably is made possible through a diminution in the vasomotor tone and a decrease in the viscosity of the blood, which together defeat the tendency of the plethora to increase the arterial pressure. It suggests that a relatively inactive vasomotor mechanism responds in the same way to its adequate stimuli as does the normal mechanism. The normal center is, so to speak, keyed to hold the arterial pressure at the normal level. The damaged center is keyed to hold the pressure at a level below the normal. And if the activity of the damaged center is constantly diminishing, the level at which it tends to hold the pressure will also constantly diminish. The reactions of the center, therefore, to increased blood volume, no matter what the new pressure normal may be, will always be such as to return the disturbed pressure to that normal. If this is the case, the combination in the late stages of shock of an increased blood volume with a lower pressure would be accounted for.

Attention should be called to the tendency exhibited by overdoses of glucose solutions to diminish the coagulability of the blood. As a result of this action, wounds which have ceased bleeding may become covered with an ooze of blood, sometimes quite considerable in amount, which remains fluid for some time. In none of our experiments was this secondary hemorrhage serious, but it is a danger which should be kept in mind when sugar injections are employed in the treatment of shock in the wounded.

SUMMARY

1. Glucose injected intravenously at rates varying between 0.57 and 4 gm. per kilogram per hour for from twenty to sixty minutes into anesthetized dogs reduced to a state of "shock" (by partial temporary occlusions of the inferior cava or aorta) has been observed uniformly to increase the mean arterial pressure.

2. The injections have uniformly produced a marked increase in the pulse amplitude, indicating a condition of plethora.

3. The increase in pulse amplitude has usually been more striking than the increase in arterial pressure.

4. In one case the increase in pressure determined by the injection of glucose continued after the cessation of the injection until the pressure was approximating the normal.

5. A subtolerant dose has raised the arterial pressure and increased the pulse amplitude as effectively as many of the injections made at more rapid rates.

6. With the more rapid injections, a marked hemorrhagic tendency may develop in animals in this condition.

7. No other palpable deleterious effects were observed.

CONCLUSION

On theoretical and experimental grounds supported by some clinical evidence, it would appear that intravenous injections of glucose at appropriate rates are of distinct benefit in certain phases of shock.

SYMPTOMATOLOGY OF THE NERVOUS SYSTEM

IN CHRONIC INTESTINAL TOXEMIA *

G. REESE SATTERLEE, M.D.
AND
WATSON W. ELDRIDGE, M.D.
NEW YORK

Present medical progress tends toward diminishing the number of disease entities rather than toward their multiplication. In no field is this more strikingly apparent than in the newly found and rapidly developing relationship between mental and nervous conditions and disturbances of the gastro-intestinal tract.

The symptomatology referring directly to the intestinal tract is not within the scope of this paper. However, it is difficult to find any case in which, on close investigation, symptoms referring directly to the intestinal tract are absent. The error in diagnosis as to the fundamental condition can frequently be explained by the fact that the gastro-intestinal disturbances are so often considered secondary to a disturbed nervous system, when in reality the opposite is true.

As an example of one of the commonest misapplications of diagnosis we mention neurasthenia. It is perfectly true that we may have a neurasthenia brought on by causes not connected directly with the intestinal tract, and in these a functional disturbance of the stomach and intestine may follow. Church and Peterson mention that neurasthenia may be caused by organic conditions such as phthisis, Bright's disease, diabetes, gout, rheumatism, and uremic and toxic states generally. The fact that chronic gastro-intestinal conditions are almost invariably followed by neurasthenia of differing intensities is not mentioned.

For purposes of simplification we have separated the symptomatology of the nervous system in connection with chronic intestinal toxemia into four classes, namely, cases involving (1) the mental system, (2) the sensory system, (3) the motor system, and (4) the sympathetic system. These classes of symptoms may occur separately or in combination, usually the latter, so that we can designate them only according to the predominant symptoms. It would be impossible to say why the toxin resulting from these intestinal conditions should have a selective affinity for any one part of the nervous system, just as it is impossible to ascribe reasons for the localization in other toxic states resulting from tuberculosis, diabetes, gout and syphilis.

It is a significant fact that in practically all of the cases considered in this article the nervous manifestations have either cleared up or have been markedly improved by treatment directed toward the intestinal toxemia. A great many of these patients have been treated by the usual therapy for disorders of the nervous system, without result. This is not in the nature of positive proof, but is very strong evidence as to the etiology of the disturbances of the nervous system in these cases.

In considering the cases exhibiting mental symptoms, we have divided them into two groups, intellectual and psychic. Under the intellectual group we find sluggishness of mentality, dulness and stupidity, loss of concentration, loss of memory and mental incoordination. In the psychic group are included irritability, lack of confidence, excessive and useless worry, exaggerated introspection, hypochondriasis, phobias, depression, melancholic states, obsessions, delusions, hallucinations, suicidal tendencies, delirium and stupor. Of 518 cases studied for this paper, 201 exhibited irritability, 317 depression, 4 obsessions, 1 dual personality, 5 hallucinations, 4 delusions, 12 hysterical coma, 74 deep melancholia, etc.

There is no group of mental symptoms that can be said to be diagnostic of intestinal toxemia. The mental symptomatology is rather complex and may assume any one or more of the symptoms of a primary mental condition, or of syphilis. These must necessarily be excluded. As an example of mental disturbance illustrating both intellectual and psychic symptoms, the following case history is of interest:

REPORT OF CASES

Case 1.—*History.*—Miss L. E., aged 46, a schoolteacher, had been constipated sixteen years following an attack of nervous prostration. The symptoms, which began at this time and had become progressively worse up to the time when she was first seen, were intense headaches, hemicranial in type; she felt as if she had two brains, one side normal and the other side abnormal. Severe melancholia, with violent outbreaks, which was progressive, kept the patient from teaching. Twelve years ago curettage was done. Eight years ago, after a diagnosis of uterine fibroids, a hysterectomy and appendectomy were performed with no improvement. For five years she took morphin, in increasing dosage, for relief from pain in the head. She always felt uncomfortable in the abdomen, especially when standing. Ability of mental concentration was partially lost. She was much depressed.

Examination.—The roentgen ray revealed a water-trap stomach with one third retention at seven hours. The small intestine was intensely rapid. Meal was in the colon in one and three-fourths hours. Both flexures and transverse colon were very low. The urine was constantly normal except for a large excess of indican. Blood pressure for many years was around 240. The Wassermann reaction was negative. Blood analysis, chemically, showed low urea nitrogen, uric acid and blood sugar. Slightly high freezing point of serum. Subsequent chemical blood analysis showed a similar picture with the exception of a high uric acid retention. Examination of the optic fundus revealed a normal picture. This patient was in a deplorable condition, mentally and physically, and life had become a burden to her. She could work only with frequent long periods of rest.

Treatment.—She was operated on by Drs. Draper and Lynch in August, 1914. The pylorus and duodenum were normal except for some slight thickening. The gallbladder was thickened and contained one stone, the size of a marble. The stone was removed. The transverse colon showed many diverticula, one of which was solidified. This was removed. The sigmoid found bound down in a scar from a previous operation was freed. A partial colectomy (developmental reconstruction) was done. End-lateral anastomosis was effected. A partial Coffey operation was limited to three suspensory sutures to the left. There was no postoperative shock.

After an initial improvement in all symptoms the patient relapsed and came to see Dr. Satterlee four months later. She had returned to work at school against all advice. She was incapacitated again. She was sent to a sanatorium for rest, and given autogenous colon bacillus vaccine. Doses were given weekly, gradually increasing in amount. There was rapid improvement. After a short time she returned to work and remained there while receiving weekly doses of vaccine and general supervision regarding diet and hygiene. One year later the patient said that "although formerly a burden to do a pleasure, it is now a pleasure to do a burden." She was feeling much better and treatment was stopped. Six weeks later she relapsed again and returned for treatment. This caused improvement once more. She continued to alternately improve, stop treatment and relapse until January, 1916, when she had a severe relapse and again went to the sanatorium. She became very melancholic and threatened suicide. She had intense pain in the left side of the head and was very nervous and hysterical. Vaccine gave intense and severe reactions. In March, 1916, she felt so well, and had for the last month or two, that she thought she should be again dismissed from treatment. At the present time the patient is still teaching and feels well unless tired, when she has a rise in blood pressure and a moderate amount of depression.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

COMMENT

The interesting features in this case are the excellent results, especially in the mental condition, after removal of the cecocolon, the subsequent diseased condition of the remainder of the colon, and the good results from the administration of the autogenous colon bacillus vaccine. These three things point very strongly to a diseased colon, and the colon bacillus as the causative factors in this patient's condition. The high blood pressure seemed to be partially dependent on the intestinal toxemia. The former was always increased after prolonged fatigue, and at the same time the toxemia increased. The chemical blood analysis and the examination of the optic fundus showed a probability of lack of any advanced renal changes.

The following case history is an example of the predominance of psychic phenomena:

Case 2.—*History.*—Mrs. S., aged 34, with negative family history, had had three children. There was a history of typhoid and erysipelas. For five years previous to being seen she had been much troubled with gas, pain in the epigastrium and constipation, with extreme tenderness at times to the left of the umbilicus. While on her feet she is comparatively comfortable, but pain begins when lying down. She has the sensation in the early morning hours of being tightly gripped in the left side as in a vise. There is no nausea or vomiting. The patient has lost 40 pounds in the last five years. She has extremely nervous spells and wants to laugh and cry. The desire is hardly controllable at times. She is very sleepless at intervals and when so keeps the whole family awake. Her husband is sometimes at his wit's end to know how to control and keep the patient calm. When very nervous she becomes hysterical and disturbs the neighbors. She screams, laughs loudly, and one time ran down stairs and into the street in her night dress. A roentgen-ray examination revealed a water-trap stomach, and ptosed, sluggish colon. Lavage at one time showed eight hour residue in the stomach.

Diagnosis.—Chronic intestinal toxemia, water-trap stomach and ptosed sluggish colon. After treatment by diet, hydrochloric acid, massage, etc., the patient was operated on. The pylorus was high, fundus low. A long adhesive appendix with constriction was removed. Colon and stomach suspension was done. Seven months later constipation had disappeared and the patient had gained 35 pounds. Nervousness was much improved. There was occasional gas, nausea and eructations. One year later, however, the nervousness returned in marked degree and there was troublesome constipation. The patient was not sufficiently careful in diet and habits. She was again put on rigid anticonstipation diet. The foot of the bed was elevated, and exercise and fresh air ordered, with very little improvement. She was then given a course of treatment with autogenous colon bacillus vaccine. At the present time, one year later, reports show the patient to be in good physical and mental condition.

Some cases show a marked predominance of sensory symptoms. These may be classified as paresthesias, hyperesthesias, anesthesias, hyperalgesias, analgesias, myalgia, neuralgia, neuritis, perversions of taste and smell, hyphedonia, and hyperhedonia. In 518 tabulated cases, 421 patients complained of headache, 302 of vertigo, 397 of paresthesias, 387 of myalgia, 379 of "nervousness" and "nervous sensations." We have observed that as a general rule the mental symptoms were more likely to occur in patients who are highly temperamental, and the sensory symptoms in those of a phlegmatic disposition.

The following case history is illustrative of the latter type of individual:

Case 3.—*History.*—Mrs. C. M., aged 50, was of nonenteroptotic type. She had been strong as a child but subject to "bilious attacks." She was naturally a hearty eater, including meats, and always had more or less trouble with her digestion. The trouble began after the birth of her first child, twenty-one years ago. After the second child, two years later, she had a perineorrhaphy, and five years later an appendectomy and ventral fixation was done. Five years ago she had a bad attack of indigestion. A diagnosis of carcinoma of the stomach was made by the attending physician. The patient lost 18 pounds. She complained that her digestion is never right and that she has always much flatulence and sleeps poorly. There was no apparent constipation until two months before examination, when she had a fecal impaction in her right side. She wakes up at 4 a. m. with headache, pain in the back of the head and neck, nausea and marked eructations. She has pain, as she expressed it, "in every nerve of the body from head to foot." The left arm and shoulder are tender and sensitive and the teeth supersensitive. She has numbness in hands and legs. She is very nervous and has had some depression and loss of concentration. She has polyuria, urticaria, and there is an odor to the perspiration. Her chief complaint is pain in the whole body and soreness in the joints of the fingers and toes.

Physical Examination.—This revealed a muddy colored skin, dry brittle nails and hair, coated tongue, tenderness over the whole colon, splashing and crepitation over the cecum. Roentgenography revealed water-trap stomach, residual cecum and residual sigmoid. She had an enormously dilated rectum. There was no gastric retention.

Treatment.—This consisted of diet, autogenous colon bacillus vaccine, hygiene, local treatment of a rectal fissure and hemorrhoids. There were very severe reactions from vaccine, increasing pain and nervousness, lasting from twenty-four to forty-eight hours. Her symptoms, which have been chiefly neuralgic pains, nervousness, insomnia, and irritability, have been markedly relieved by treatment for chronic intestinal toxemia, which included forty doses of the vaccine. The strong reactions following vaccine administration, and the periods of marked improvement thereafter, were very remarkable and seemed to have a strong bearing on the etiology of the symptoms and on the toxemia.

The third class of cases considered, those showing symptoms of the motor system, are fewer in number than the cases with the mental conditions or those with affections of the sensory system, and form a small percentage of the total number of cases. Among these are the so-called cases of epilepsy, supposedly of intestinal origin. We are by no means able to state with certainty that these cases owe their symptomatology to the diseased condition of the intestinal tract and we are not able to cite any patient cured to date, but we do know that treatment of the diseased intestine itself and treatment directed toward the resultant toxemia has cleared up the symptoms directly referable to the intestinal tract and has produced, or been coincident with, a vast improvement in the epileptic seizures. When a relapse in the intestinal symptoms has occurred there has almost invariably been a recurrence of the epileptic seizures. We are of the opinion that a surgical procedure, such as a developmental reconstruction of the colon, in our cases under observation, would correct the intestinal condition and cure the disease. This, however, is to be proved. This class of patients will require a large amount of future study before more definite conclusions can be drawn, but the results obtained in the cases to date are very suggestive of a close relationship between these epilepsies and intestinal toxemia. The case history which follows is interesting in this connection:

Case 4.—*History.*—Miss S. K., aged 38, a milliner, brunette, was first seen five years ago. Her family history was negative for epilepsy or intestinal troubles. She had been constipated all her life, had had "indigestion" for twelve years, and was getting worse. At the age of 14 she began to have attacks of unconsciousness in which she would bite her tongue. She had premonitory aurae at times. These came on usually in the middle of the night and in the early morning hours, leaving her feeling weak and exhausted after waking. Appendectomy was performed one and one-half years ago. The left ovary was removed at the same time for unknown reasons. She always takes cathartics at night. She has frequent spells of nausea, vomiting and malaise, with much pain in the legs, knees and arms at times. A marked symptom in this, as well as in a similar case, has been a feeling of soreness, fulness and heaviness in the cecocolon previous to and during the periods of seizure, with accompanying headache.

Physical Examination.—This revealed a prominent abdomen, dilated stomach and large tender cecum. A blood analysis showed high aminonitrogen, with low uric acid, indicating loss of purin metabolism. Hepatic functional test with phenoltetrachlorphthalein intravenously showed a normal 45 per cent. recovery. The urine showed almost constantly high indican content, but few granular casts. Stool examinations revealed many unchanged muscle fibers and faint blood reaction.

The attacks were getting worse and more frequent; five or six every day. She is confined to bed altogether lately owing to these attacks.

Treatment.—The patient has been under close observation for the last five years. During this time the administration of autogenous colon bacillus vaccine has had a good effect in controlling the seizures, but the patient is still subject to relapses. At the time of these relapses the best results have been obtained by proper care of the intestinal tract and renewed injections of the vaccine. A developmental reconstruction of the colon has been constantly considered and frequently urged, but so far has been unobtainable.

The following case history is one in which marked motor nerve symptoms, resembling closely those of tetanus, was caused by strangulation, gangrene and perforation of the ileum.

Case 5.—*History.*—Mrs. F. DeN., aged 30 years, had three weeks previous to examination an incised wound of the finger, which healed. Two weeks before examination she had an attack of severe vomiting lasting four or five days, with constipation. Two days before coming under observation she developed a stiffening and gradual inability to open the jaws. Her physician thought the condition to be one of tetanus and sent her to the hospital.

Examination.—This revealed a well developed and nourished woman in good mental condition, but the inferior maxilla was firmly fixed to the upper, and there was marked stiffness of the neck muscles. There was a small insignificant healed scar on the finger. There was no distention of the abdomen, and no rigidity or tenderness there. The temperature was normal, the pulse 99. The heart and the lungs were normal. No symptoms occurred until twenty-four hours later, although the jaws did not relax. A convulsion then occurred with opisthotonus, complete muscular rigidity and cyanosis, and the jaws relaxed. She was given camphor and oxygen and the condition passed off in ten minutes. Three hours later she became suddenly completely rigid, cyanotic and died. The temperature had risen to 100.5 and the pulse to 110.

The postmortem examination revealed an omentum all curled up in an effort to wall off an infective process in the pelvis. The peritoneum over the whole intestinal tract showed an intense inflammatory condition. Newly formed adhesions matted together the entire tract. There was in the pelvis a gangrenous loop of ileum about 8 inches in length, which was perforated in several places and covered by omental tissue. No cause for this condition could be found, but the most likely thing seemed to be a preexisting volvulus. The brain and coverings were normal except for a mild edema and congestion. Postmortem cultures, aerobic and anaerobic, from the spinal fluid and blood failed to show the presence of any organism.

The conclusions drawn from this interesting case are that it was a toxemia resulting from the obstruction and gangrene of the intestine, and not a case of tetanus.

In 1908, Draper[1] called attention to a similarity between so-called tetany in human beings and the symptoms of duodenal obstruction in dogs, which is interesting in this connection.

The subject of the involvement of the sympathetic system is of such a broad scope that to go into it with any detail except in certain definite phases is impossible on account of its complexity. We have yet to find a case in which there was not present some involvement of the sympathetic system, but in some cases this is much more pronounced then in others. The symptoms that are most characteristic and directly attributable to irritation of the sympathetic system are: (1) the cardiac symptoms, including tachycardia and palpitation; (2) peripheral vasomotor symptoms, such as diminished blood supply to the skin, dry brittle hair and nails; (3) gastro-intestinal symptoms, including disturbances of taste and smell, appetite, nausea, vomiting, changes in the secretion of the digestive juices, constipation and diarrhea, and (4) disturbances in the endocrine system, with hypothyroidism, hyperthyroidism, alteration in the secretion of the suprarenals and other glands of internal secretion.

Direct connection between intestinal conditions and disturbances in the glands of internal secretion are often highly problematic. Of the symptoms mentioned, we find in the order of their frequency constipation, disturbances in skin nutrition, changes in the secretion of the digestive juices, loss of appetite, ageusia, nausea, changes in the rate and rhythm of the heart, with the subjective symptom described by the patient as "palpitation," and the syndrome of hyperthyroidism. The constipation may be the cause or the result of the toxemia. In the latter case this may be due to the disturbance of the sympathetic system.

It is in the disturbances of the nutrition of the skin that we see the first marked improvement from treatment. A dry dusky skin will often become moist and clear after the intestinal toxemia is controlled.

We have found that in all our cases of intestinal toxemia in which there has been a perverted ductless gland system, only occasional improvement has followed the administration of organotherapeutic prod-

---

ucts. On the contrary, the symptoms coming apparently from a perversion of these glands have been improved by the treatment directed toward the intestinal tract and the intestinal toxemia as the primary cause. As one instance of disturbed glandular system may be mentioned a patient apparently suffering from hyperthyroidism, to whom thyroid extract was administered. The result was a very marked hyperthyroidism. Following this some of the common antithyroid measures were adopted without result. Subsequently the patient made a slow but good recovery under treatment for intestinal toxemia. It is a common thing to see an enlarged thyroid with symptoms of hyperthyroidism subside under the treatment for intestinal toxemia.

CONCLUSIONS

The nervous system is almost invariably affected in whole or in part by chronic intestinal toxemia.

The nervous symptoms are often the most prominent in the symptomatology.

A thorough investigation of the gastro-intestinal tract is essential in cases exhibiting a chronic symptomatology of the nervous system provided the usual obvious factors of etiology of disturbances of the nervous system can be excluded.

Disturbances of the gastro-intestinal system are more often the cause of a nervous symptomatology than the result of a diseased nervous system.

In doubtful cases a proper hygiene and therapy of the intestinal tract will often be the deciding factor in differential diagnosis.

125 West Fifty-Eighth Street.

ABSTRACT OF DISCUSSION

Dr. J. Russell Verbrycke, Jr., Washington, D. C.: It seems to me that the nervous system and the gastric system in autointoxication should be considered in the light of a vicious circle. Either system can start the trouble which can then be taken up by the other, and in my experience, considering either system by itself has not resulted in curing the condition. We have to treat the autointoxication by appropriate measures, and with that we have to employ a lot of suggestion to the patients to keep them encouraged. We really know hardly anything of the actual causative factors of intestinal intoxication. We have not been able to separate the individual poisons; we have, however, some idea of the degree of poisoning in the estimation of indican. There is some difference of opinion as to the importance of indican as an index of intestinal intoxication. Recently, I analyzed a series of several hundred cases in which indican was persistently present, and I found on tabulating these cases that 98 per cent. had two or more of the symptoms which we consider to be those of intestinal intoxications or other intoxications. We know several characteristics of the toxins generated in the bowel. We know they are rapid in action and rapid in excretion. A patient may come to us having marked symptoms of dizziness or headache and after one colonic washing the headache and dizziness may disappear; patients often go out of the office relieved. We know, furthermore, that in addition to the rapidity of elimination the patient builds up a resistance to the intoxication, and a patient who at one time shows constant indicanuria, if he has a recurrence, though it is much less in degree than the first attack, feels it a great deal more. The most common symptoms are referable to the nervous system, and I have found that in 67 per cent. of the cases in which there is inability to concentrate, the analysis will show indican. In my experience patients who do not show indican invariably show regurgitation through the ileocecal valve. These have been the most difficult to treat.

Dr. Satterlee mentioned that some of these cases frequently extended over a period of two years. I confess I would be discouraged before the two years were up, but the average case certainly does not take a very long time to improve. Once in a while, however, we do have a very resistant case.

Dr. Fenton B. Turck, New York: Twenty-five years ago when I took up research work on the alimentary tract two explanations were usually given of the causes of intoxication from the gastro-intestinal tract. One was mechanical obstruction of some form or degree, and where no mechanical obstruction could be shown it was concluded that these cases were of nervous origin. The nervous system was held to be the prime factor causing muscular contraction and rhythmic motion of the stomach and intestines. Physiologists later found, after removal of all nerve supply from the muscles, that rhythmic motion continued the same, the nervous system acting as a coordinating mechanism.

My experiments indicated that not only were the muscle cells the prime factors in physiologic function, but atony was closely associated with a bacteriologic problem, the intestinal flora. I found that the muscle cells which were involved undergo a degenerative change with loss of motor power *pari passu* with venous stasis of the splanchnic circulation. Recently (*Bulletin of the Medical and Surgical Faculty of Maryland*, December, 1916, and *Boston Medical and Surgical Journal*, May 10, 1917) I published some interesting experimental and clinical facts showing that the individual muscle cell is the first to be acted on by the factors which produce chronic atony and dilatation.

Fatigue, distention, venous stagnation, toxic absorption and bacterial permeation serve, each in its turn, to exhaust, stretch, stifle, poison and break down the structural units that make up in their sum the muscular wall. Tissues which have shown the atony of dilatation will demonstrate under the microscope the changes undergone by muscle plasma, and, in many cases, will give unmistakable evidence of the special action of vascular or bacterial factors.

The occurrence of colon bacilluria is often presumptive evidence of absorption in spite of the bactericidal function of the submucous tissue.

To sum up: (1) Muscular inefficiency of the gastro-intestinal tract is the basis of the greater part of chronic perversion of digestive function. (2) Experimental atony and dilatation are brought about chiefly through mechanical distention, fatigue and the multiplication of the intestinal flora. (3) Microscopic sections of atonic tissue show the factors of venous stagnation and the permeation of the intestinal wall by bacteria from the lumen; muscle cells of such tissue under the microscope are seen to be in an advanced degree of degeneration. We have here biologic principles to grapple with.

Dr. E. E. Smith, New York: In a paper on the "Etiology of Idiopathic Epilepsy" by Dr. Herter and myself, published in the *New York Medical Journal*, twenty-five years ago, we called attention to intestinal toxemia as a causative factor in epilepsy, reaching the conclusion that seizures were determined in certain cases by the absorption of toxins from the intestinal tract.

The present views in regard to this interesting subject are conveniently expressed by three types which we keep in mind: First, protein sensitization is the condition which first receives our attention with those patients in whom there are skin eruptions; the second type is the arthritic case, and in these cases attention is first directed to localized foci of bacteria; the third class of cases is the type before us today, the nervous cases, in which we direct our attention to toxemia from absorption of chemical substances from the intestines. These are not fixed types, and one condition may often be found with either of the others.

Relative to the intestinal toxemia, we now know of substances formed by putrefactive processes that are entirely capable of giving rise to symptoms in the nervous system, namely, the amins, and particularly the derivatives of ethylamin. There is an exaggeration of the action of particular glands through the formation of certain of these amins, since they are similar in their pharmacologic action to the autocoids of the glandular secretions; and we have, as a result, this perversion of the functions of the nervous system.

If the process in the intestine goes on to a point where there is actual bacterial invasion of the tissues of the intestine, then we have a class of cases in which, in addition to chemical intoxication, we have bacterial infection. These are the cases in which the administration of autogenous vaccines, properly prepared, are giving good results; in other words, in those cases in which we have a mixed condition of chemical poisoning and bacterial infection. Thus, we may have in any of the conditions mixed processes that go on and give rise to and explain various symptoms.

Dr. Nathan Rosewater, Cleveland: It has been said, by Dr. Turck, I believe, that a mechanical cause is not sufficient to explain these cases. In cases of headache due to mechanical causes, particularly from constipation, the relief is almost immediate after taking a cathartic or enema, showing that there was a mechanical cause, not a toxemia. If it were toxic it would take twenty-four hours or more before we could remove enough of the toxic matter absorbed from the bowels into the circulating fluid; so that there is a large class of cases of this purely mechanical type. On the other hand, what is required is a differentiation between the intestinal and nonintestinal toxemias, particularly noting the time of day when the symptoms occur and whether mixed or simple in type.

In cases of simple indican, toxic fatigue occurs at any time of the day, lasts any length of time, but may be complicated. There may, however, be an entirely different type not clearly described heretofore. The patient wakes up in the morning after rest and sleep (fatigue antidotes) with a dry mouth, depressed in spirits, feeling tired and aching all over—muscular rheumatism, so called—and yet as a proof that it is not due to fatigue at all, such a patient, who may be a washerwoman, will, after waking up lame and exhausted, do a hard day's work, and will feel better and be entirely free from trouble in the afternoon and evening. Fatigue would not improve with exercise, nor would neurasthenia. We are dealing here with a type of case which resembles, but is entirely different from, indicanemia or neurasthenia, and which occurs in the early morning and passes off during the day, especially with exercise, massage, etc. There are generally, also, pains in these cases which occur in the early morning, and the pain is so severe at times that it must in some cases be distinguished from appendicitis. If the abdominal muscles are touched in the early morning they are very sensitive, but the oftener you press, the less sensitive they are. Such cases are numerous and are due to purin substances in the foods—purinemia—and not to intestinal toxemia. There is no indican excess in these cases. When the patients are taken off of purin foods they rapidly improve; even though subjected to harder work than ever they do not complain of the old feeling of fatigue, which should be called pseudofatigue.

Dr. G. Reese Satterlee, New York: Our paper was not intended to be a discussion on the etiology or treatment of intestinal toxemia. There was an interesting point, however, brought out by Dr. Verbrycke, who spoke of suggestion or mental therapy in these cases. I will say that it is extremely important. I do not believe that any one could hold a patient for two years unless he used suggestion or mental therapy along with his treatment.

I called attention to the length of time it takes for a patient to get over an intestinal operation. It does take at least one or two years, and if we can cure them in two years without an intestinal operation, we are at least doing as well as the surgeons.

We find indican not at all diagnostic. It might be diagnostic of putrefaction. Dr. Verbrycke spoke about the difficult cases of regurgitation into the ileocecal valve. I think they may be associated with indicanuria. We found that patients in a large percentage of cases of chronic intestinal toxemia have no indicanuria. They may have intestinal putrefaction at one time or another, but a great many of the patients do not have ileocecal regurgitation. Every patient has a rectal injection, so we are sure, as far as the technic can go, that we have no regurgitation. Without indicanuria and without regurgitation the patients are fairly easily taken care of.

Dr. Smith very aptly spoke of two kinds of intestinal conditions: toxemias with putrefactive substances, the amins, in the intestinal contents and those in which the wall of the intestine is involved, in which we are dealing with a bacterial infection. In the latter condition he considered vaccines useful. This is exactly what I have brought out. To sum up, intestinal putrefaction in simple cases may be cleared up by catharsis and starvation, and the other more difficult conditions, in which the wall of the intestine is infected, must be handled by diet, mental suggestion, hygiene and autogenous colon vaccines. In our experience the autogenous colon vaccines are most essential.

A NEW COMPLEMENT FIXATION REACTION AS APPLIED TO LEUKORRHEA

A COMPARATIVE STUDY OF FORTY-SEVEN CASES

LOUIS D. SMITH, B.S., M.D.
AND
F. LEE STONE, M.D.
CHICAGO

The difficulty of making an absolute diagnosis of gonorrhea in woman by a combination of clinical history, signs, symptoms and the usual laboratory methods has led us to undertake a comparative analysis of forty-seven cases of women suffering from leukorrhea, employing the usual methods and the complement fixation test devised by one of us (Smith). It is further desired to submit these records statistically, to form a basis of estimate of the value or accuracy of this reaction.

In entering on these experiments, we were immediately impressed with the insecurity and lack of value of all ordinary methods to serve as a criterion for diagnosis to substantiate our findings. For who, by the methods at our command, can with absolute assurance delegate a woman suffering from leukorrhea to the categorical diagnosis of gonorrhea?

In conducting the special test, it was deemed advisable, in order to eliminate bias, to do so without a knowledge of the nature of the case. Accordingly the specimens were submitted in serial numbers to one of us (Smith), and the other data were kept separately (Stone) until after the report of the test, when all ascertained facts were coordinated. In this manner the special test under trial was performed without any guiding influence, and the other laboratory examinations were made without knowledge of the outcome of this test.

The principle of the test involved is that of the Bordet-Gengou complement fixation reaction. In our test the antibody of the bacteriolytic system is supplied by commercial antigonococcic horse serum, and the antigen is the unknown element. This antigen is embodied in the suspension of the leukorrheal discharge which, although gonococci may be few, nevertheless contains the products of their interaction with the tissue and also their own autolytic products. In other words, the principle of the Wassermann test is reversed, in that in the latter the unknown element is the antibody in the patient's blood, and the known antigen is tissue extract, whereas in our test, the antibody is supplied, and the antigen (identical with the gonococcus or its products) is the unknown factor. Thus employing its principle it is possible to determine at its very inception a gonorrheal infection in male or female, and similarly to determine the time of disappearance of the organism according to experiments we are now conducting.

TECHNIC OF TEST

A specimen of the discharge is collected from the cervix and vagina on a long cotton swab. The swab is immersed in about 2 c.c. of physiologic sodium chlorid solution. The discharge is freed from the swab and ground finely with the sodium chlorid solution in a glass mortar. The suspension thus prepared is permitted to stand over night and then heated at 56 C. (132.8 F.) for half an hour. In appearance a properly prepared suspension exhibits a faint turbidity, to obtain which it may be necessary to add more sodium chlorid solution. Practice will enable one to determine the proper dilution. Floating particles may be removed by a few seconds of centrifuging.

* In this table, + denotes positive; — negative; ? question; 0 no examination made; 4+ four positive.

In the test a positive and negative control should be used, each specimen requiring ten tubes (as used in the Wassermann test), consisting of a first and second row of four tubes, and single tubes in the third and fourth rows. In all tubes are placed 2 c.c. of physiologic sodium chlorid solution. To the first tubes of the first and second rows is added 1 minim of the suspension, in the second tube 3 minims, in the third 5 minims, in the fourth 7 minims. In the single tube of the third row are placed 7 minims of the suspension. In all the first row tubes and the single tube of the fourth row is now placed 1 minim of the properly standardized antigonococcic serum. In all tubes excepting the single third row tube is now placed guinea-pig serum (complement) as is done in the Wassermann test. The specimens are now incubated in the water bath for one-half hour at 37 C. (98.6 F.), when the antisheep amboceptor and sheep corpuscles are added and reincubated. Readings are then taken. The first row constitutes the test, the degree of inhibition of hemolysis indicating the degree of positiveness, if the corresponding second row, which is the control for the test row, has completely hemolyzed. The third row tube is a control on a possible hemolytic tendency of the specimen to be tested, whereas the fourth row tube is a control on the anticomplementary action of the antigonococcic serum.

The accompanying table indicates our findings. By the caption "history and evidence" is meant a combination of conditions such as known exposure, infection of others, pain and burning on urination, profuse leukorrheal and urethral discharge, etc.

An analysis of the table elicits the facts that in only two instances, Cases 6 and 9, was a negative test obtained when there was evidence of gonorrhea, Case 6 having presented a bartholinian abscess that had been cured. However, in these two instances slide examinations and blood complement fixation tests were negative. In seventeen cases with positive clinical evidence and negative slide examinations, our complement fixation reaction was positive. In four cases without clinical appearance of gonorrhea, the test was positive in two and doubtful in two. Five cases doubtful clinically yielded positive reactions. Three cases with positive clinical evidence and positive Smith test exhibited positive blood complement fixation reactions.

CONCLUSIONS

In view of the fact that we have no real basis for comparison of the test under discussion, time and additional work are necessary to establish its value. It is feasible theoretically because it involves the principle of the Bordet-Gengou complement fixation reaction. In our experience it has been of great value in confirmative diagnosis of gonorrheal infections. It has served, finally, as a guide in determining cures.

Method to Determine Total Amount of Blood in the Body.—The *Correspondenz-Blatt für Schweizer Aerzte* gives brief summaries of some of the German medical journals, and in a recent issue describes M. de Crinis' method of determining the total amount of blood in the body by refractometry. With a Pulfrich refractometer and Reiss' tables he estimates the proportional albumin content of the blood from a specimen of serum after centrifugation. Then the blood is artificially diluted by injection of 500 c.c. of physiologic saline, and after ten minutes another specimen of serum is centrifuged and the percentage content of albumin determined. To avoid error from loss of fluid by skin and kidneys during the interval, he actually injects 550 c.c. of the saline but computes only for the 500 c.c. The total amount of blood thus determined for healthy persons ranged from 3,300 to 5,600 c.c., equivalent to from 5.98 to 7.5 per cent. of the body weight. His research showed further a fairly constant figure for the total blood amount in individual cases for weeks at a time. The original article is credited to the *Zeitschrift für physiologische Chemie,* 99, 131.

Clinical Notes, Suggestions, and New Instruments

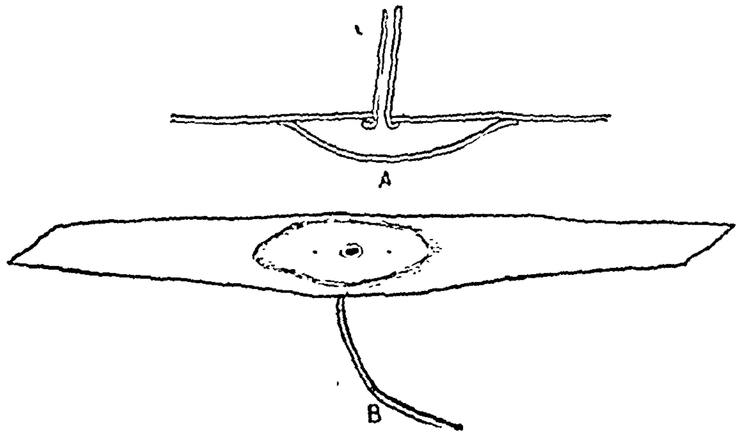
POSTOPERATIVE DRESSING FOR CHOLECYSTOTOMY

Charles H. Breuer, M.D., Lincoln, Neb.

The dressing here described has been adopted in my work in gallbladder cases in which a rubber tube drain is left, for the purpose of eliminating the troublesome and messy pad. These cases, if they drain at all profusely, require changing of the pad from one to three times a day, and usually a large stack of dressings is found saturated with the discharge.

The dressing is made from the rubber umbilical belts made for the umbilical hernia of infants. This belt consists of a band of pure rubber, to extend around the abdomen, with a pneumatic pad in the middle. The pad is inflated by a rubber tube. A section is shown at *A* in the illustration. The rubber pouch which is cemented to the under side of the belt is trimmed away with a pair of scissors, leaving the belt with the tube attached, with the opening on the reverse side of the belt.

After the cholecystotomy case has progressed so far that all drainage can be withdrawn, and only a fistula is left, this belt is sterilized and fastened over the wound, so that the opening into the rubber tube comes just over the fistula. The band is held in place by straps of adhesive plaster. The discharge from the fistula is thus enabled to pass through the rubber tube, into a bottle, just as if the rubber drain were still in place.



Postoperative dressing for cholecystotomy: *A*, diagram of air cushion on umbilical belt; *B*, umbilical belt trimmed for use.

This effects a great saving in time, trouble and dressings, as well as affording the patient a great deal of convenience over the old method.

THE TREATMENT OF URETHRAL CARUNCLES BY FULGURATION

Edgar G. Ballenger, M.D.
Fellow of the American College of Surgeons
and
Omar F. Elder, M.D., Atlanta, Ga.

Not having seen a report of the employment of the high frequency current in the treatment of urethral caruncles, we desire to direct attention to the value of this method of destroying these troublesome growths. Our first experience with fulguration thus used was about two years ago when we fulgurated a large caruncle which had persistently returned over a period of several years after excision once, destruction by the actual cautery three times, and treatment with various cauterizing chemicals. We, as well as the patient, were much discouraged with the results obtained. We explained that fulguration treatment might succeed in preventing a return of this painful vascular tumor, and the patient readily consented to try this method. The surrounding tissue was infiltrated with a 1 per cent. solution of novocain, and the d'Arsonval current was applied until all of the red growth was whitened. Less pain followed the treatment than had followed any of our previous treatments, and at the end of two years there is no return. Slight bleeding occurred at times as the fulgurated mass separated from the surrounding healthy tissues. There has not developed any narrowing of the urethral canal. Two others have been treated in this manner. One required only a single treatment, as the caruncle was small. The other required two fulgurations, as the growth was massive and so surrounded the urethral canal that we were afraid to attempt a total destruction, as we could not determine the limitations of the growth until it was reduced in size.

The patients have all remained well, though sufficient time has not elapsed to permit us to say they are absolutely cured. We can say, however, that they appear normal, one after two years, one after six months and one after two months. The technic of the procedure is much simpler and easier than excision, and the inconvenience to the patient vastly less, as the fulguration may be performed under local anesthesia.

INDIA INK INFILTRATION: A SIMPLE AND EFFECTIVE SUBSTITUTE FOR CORNEAL TATTOOING*

F. H. Verhoeff, M.D., Boston

The method of tattooing corneal scars hitherto employed has consisted in making numerous needle pricks in the scar and then rubbing into them a paste of India ink. It is necessary to repeat this process many times with sufficiently long intervals to allow the inflammatory reactions to subside. This method has given such unsatisfactory results that corneal tattooing is now seldom attempted, either for cosmetic or for optical purposes. Moreover, it is open to the objection that it exposes the eye to serious danger of infection, and when the iris is caught in the scar, even to the danger of sympathetic uveitis.

Several years ago it occurred to me that a simpler, safe and generally more satisfactory method of darkening corneal scars would be to inject the pigment or coloring matter into the tissue by means of a hypodermic syringe. I therefore tried this method, but instead of making use of India ink, I employed a 20 per cent. solution of argyrol in the hope that permanent argyrosis would be produced. The result was most brilliant for about a week, at the end of which time the superficial layers of the scar were cast off, evidently because of necrosis from the toxic action of the argyrol. This made the scar thinner and much less noticeable, but of course was not the desired solution of the problem. It was noteworthy that the argyrol solution remained in the place it was injected and did not diffuse into the surrounding tissue to the slightest extent, thus proving that the penetrating power claimed for argyrol does not really exist.

Recently I have tried the method again in three cases, using India ink instead of argyrol, and the results have been entirely satisfactory. I made use of an ordinary small glass hypodermic syringe and a medium size needle (26 gage). A very small needle might tend to become plugged by the ink particles. The India ink, in stick form, was rubbed up in a small amount of physiologic sodium chlorid solution until a sufficiently black suspension was obtained. The fluid was then drawn up into the syringe through the needle, a piece of cork placed on the end of the needle, and the whole sterilized by boiling. The eye was then cocainized and held firmly by fixation forceps. After the syringe had been cooled and all air carefully forced out of it, the needle was introduced into the scar near the margin and the point pushed just beyond the center. The fluid was then slowly injected until only a narrow rim of the scar remained unblackened. In two of the cases it was necessary to insert the needle in two or three places to obtain this result, owing to the large sizes of the scars. The reason for not forcing the fluid quite to the margins of the scars was to avoid the possibility of its suddenly breaking its way into the normal corneal tissue. The uninjected margins of the scars, however, in none of the cases were sufficiently conspicuous to interfere with the cosmetic results.

---

* From the Massachusetts Charitable Eye and Ear Infirmary.

Great care was taken not to force the needle into the anterior chamber.

Following the operation, the eye in each case showed a slight reaction which subsided in about a week. In the course of a few weeks, the blackening became more uniform so that the ultimate results were superior to those immediately obtained. These results were far superior to those of any tattooing operations I have seen, and owing to the large amount of pigment injected and its depth in the tissues, there is every reason to believe that the improvement will be permanent.

DILUTING FLUID FOR COUNTING BLOOD CORPUSCLES

Jacob Diner, M.D., New York

The need of a good diluting fluid for the purpose of counting blood corpuscles has often been impressed on me while working in the laboratory and in hospitals. Those mentioned in textbooks have many drawbacks. Some form a precipitate on standing; others while remaining clear do not permit of the addition of staining solutions so that the white corpuscles may be differentiated from the red corpuscles while making the count; still others destroy the red corpuscles if the diluted blood is permitted to remain in the counting pipet for some hours.

With the object in view of securing a fluid which will do away with the objections mentioned, I have done some work along this line and have obtained what I believe to be an ideal diluting fluid. This fluid permits of the simultaneous counting of white and red corpuscles; it keeps indefinitely without precipitating; it retains the normal shape of the corpuscles, and the diluted blood kept in the diluting pipet for over a week was as perfect as when first drawn. The formula is as follows:

Sodium chlorid	0.85	gm.
Sodium citrate	2.00	gm.
Azure II	0.001	gm.
Formaldehyd solution, U. S. P.	3	drops

Distilled water enough to make 100 c.c.

The sodium salts are dissolved in the water, the formaldehyd solution is added, the azure is added, and it is shaken well. It may be kept in any kind of a bottle.

The technic of using it is the same as with Toison's, Hayem's, or any other fluid. The findings are computed according to the degree of dilution.

FRACTURE OF ISCHIUM

Albert Franklin Tyler, B.Sc., M.D., Omaha

Fracture of the ischium is so rare that the following case is worthy of attention. The history of the accident as given by the patient is interesting.

W. S., a robust man, said that two days previously he had fallen in such a manner that he landed on the buttocks in the sitting position. A half buried brick protruded from the ground so that the force of the fall drove the brick against the right buttock. He tried to rise to his feet, and as he assumed the standing position there was a loud snap and he fell to the ground a second time. Thereafter he was unable to use the leg, and suffered intense pain when any effort was made to do so.

The man lay on the left side with the right leg flexed at the knee. Any attempt to extend the leg produced pain in the right buttock. Pressure over the region of the tuberosity of the ischium elicited severe pain.

Roentgen examination revealed a fracture through both rami of the ischium, the anterior being at about the junction of the ischium and pubic bone, the posterior extending through the acetabulum.

The patient was kept in bed on the left side with the right leg flexed at the knee. Recovery has been slow, but is good as far as function is concerned.

It would seem that when the patient's buttock struck the brick, only a partial fracture occurred, which was completed by the muscle strain incident to rising to the erect position.

Military Medicine and Surgery

PITCHING AND STRIKING THE UNITED STATES ARMY FIELD HOSPITAL

WILLIAM W. RENO, A.M., M.D.
Lieutenant-Colonel, Medical Corps, U. S. Army
FORT RILEY, KAN.

The ability to pitch or strike its field hospital in a very short time is a necessary accomplishment for every field hospital company. Speed in these two operations will often spell success in the evacuation of the wounded in time of war. As every civilian physician who joins a field hospital company will be confronted with these necessary procedures, their anatomy will be presented in detail. The first essential is to learn how to pitch, strike and fold army tentage.

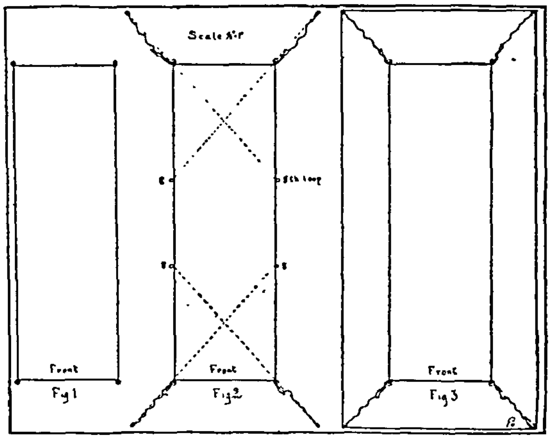


Fig. 1.—Pitching tentage, first step: Tent pinned to the ground by its four corners. Always draw wall taut and then slacken 4 inches before driving the corner pin.

Fig. 2.—Second step: The four corner guy pins added, and ropes placed over them.

Fig. 3.—Third step: Storm guys stretched for alining guy pins.

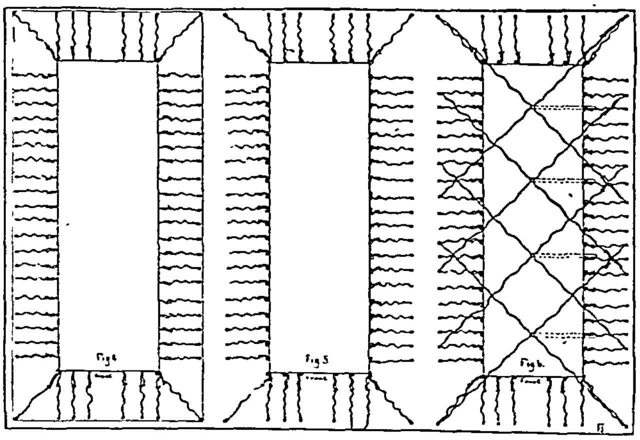

Fig 4.—Pitching tentage, fourth step: Guy pins driven inside of ropes, opposite wall loops, and guy ropes, fully slackened, placed over pins.

Fig. 5.—Fifth step: Wall pins driven through wall loops on Sides 1, 2 and 3, and at (not through) wall loops on Side 4; wall loops removed at LECWP and LRCWP.

Fig. 6.—Sixth step: Uprights placed, hoods and storm guys adjusted; men creep under tent, raise, and then adjust uprights and ropes. Storm guy, a long rope over tent.

PITCHING

The field hospital company is divided into tent pitching squads, each of eight men and an NCO. Each squad is divided into four minor squads of two men each, numbered Minor Squad 1, Minor Squad 2, Minor Squad 3 and Minor Squad 4. The four sides of a tent are numbered 1, 2, 3 and 4, Side 1 being the front side, and the others, 2, 3 and 4, numbered as the hands of a clock travel, that is, No. 2 to the right, No. 3 to the rear and No. 4 to the left. Each minor squad pitches and strikes on the side of its number, as Minor Squad 1 on Side 1, etc.

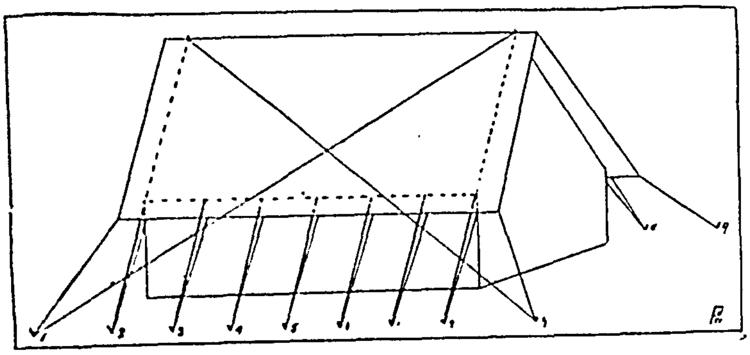

Fig. 7.—View of hospital tent and fly: Ropes go to pins as indicated; 1 and 9 are 8 feet from the corner wall pin; 2 and 8 are 2 feet from 1 and 9; corner guys of tent are on 2 and 8.

ABBREVIATIONS

RFCWP, right front corner wall pin
LFCWP, left front corner wall pin
RRCWP, right rear corner wall pin
LRCWP, left rear corner wall pin
NCO, noncommissioned officer

(*a*) The tents are unrolled. Squad 1 drives RFCWP, places RFCW loop over RFCWP, and ties the front door with a wall pin through the proper wall loop. (The proper wall loop is found as follows: For hospital and wall tents the two wall loops at the ends of the sod-cloth (the canvas apron below the walls) are used, one being slipped through the other and a wall pin being thrust through the free one. For ward

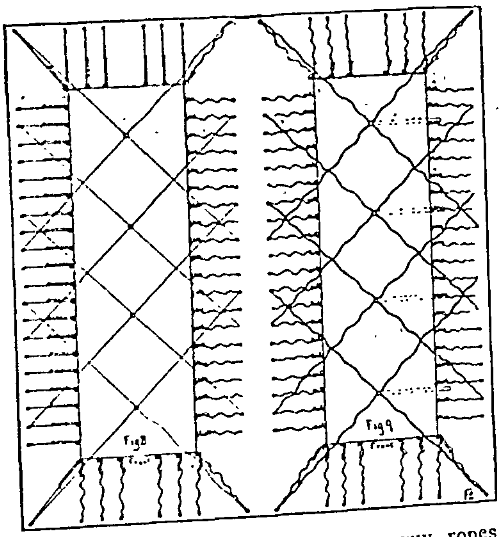

Fig. 8.—Striking Tentage, first step: Loosen guy ropes on Sides 1 and 4. (Do not remove from pins. Loosen on Side 4 only if no guy ropes on Side 1.) Also remove wall loops on Side 4, including corners.

Fig. 9.—Second step: At command "down," men carry bases of uprights through Side 4, then remove all pins except R and LRCWP for pyramidal tents or RF and RRCWP for all other tents.

and pyramidal tents, the wall loop at the end of the sod-cloth is slipped through the loop where a rope is tied to the end of the door, and the wall pin is thrust through the wall loop. The rear door, if there is one, is tied in the same manner.) At once Squad 4 places LFCW loop over LFCWP, and drives the pin after the other tents. Squad 2 places the NCO a RRCW loop over RRCWP, and drives the pin. Squad 3 places LRCW loop over LRCWP, and drives the pin. The tent is now pinned to the ground by its four corners (Fig. 1).

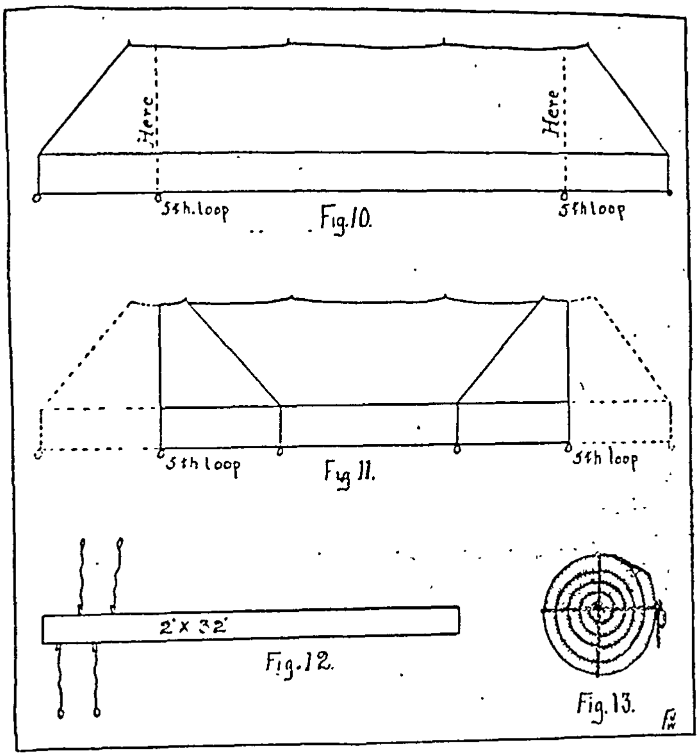

Fig. 10.—Folding, first step: Draw tent away from tent site until taut on two corner pins. Fold ends to lines marked "here."

Fig. 11.—Second step: Place all guy ropes and hoods on tent near apex. Fold from apex in 2 feet folds until in a long, slender rectangle about 2 by 30 feet.

Fig. 12.—Third step: Roll tightly from one end and tie at other with four guy ropes around circumference.

Fig. 13.—Fourth step: Tie this drum shaped package in a manta, if there is one.

(*b*) Each squad now drives its corner guy, using a guy pin, which is exactly 2 feet long, as a measuring stick. The guy pin is driven, for square or approximately square tents, in a line diagonal with the opposite corner. For the ward tent, which is a long tent,

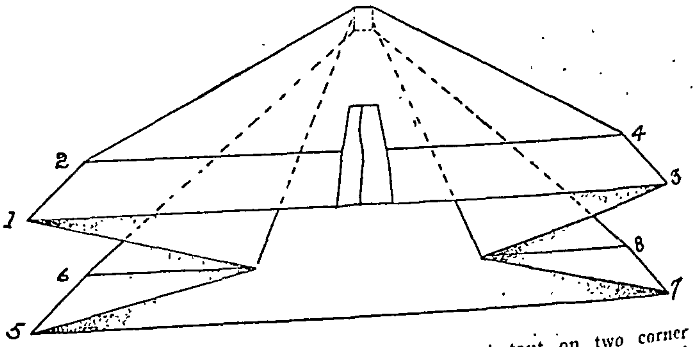

Fig. 14.—Folding pyramidal tent: Draw tent taut on two corner wall pins. Carry 1-2 over to 7-8. Return and cover 5-6, smoothing out folds. Now carry 3-4 to 5-6, return and cover 7-8, smoothing door and any folds. This makes the tent bellows-shaped. All this time the metal square at the apex is held taut and perpendicular on the ground. Now place hood in apex square and fold from top to bottom in apex-square-width folds. Then fold from each end and tie with two interior guys, fully slackened.

the diagonal crosses the tent at the eighth wall pin on the opposite side instead of at the corner (Fig. 2). The distance of the corner guy pin from the corner wall pin is as follows: 6 feet for the small wall tent and the small pyramidal tent; 7 feet for the pyramidal tent; 8 feet for the wall and the hospital tents, and 11 feet for the ward tent.

(*c*) Four wall pins and four guy pins are now in the ground for each tent. At once storm guy ropes (braces) or hood guy ropes are stretched between the corner guy pins on every side where guy pins are to be inserted (Fig. 3). These mark the line for the guy pin sites. Just inside this rope a guy pin is driven to match every wall loop seen on the tent. All guy ropes, fully slackened, are placed over these pins in proper order (Fig. 4). Now, for the pyramidal tents, all wall pins are driven through the wall loops, the bottom tent wall edge being first made perfectly straight. For all other tents on Side 4, wall pins are driven at wall loop site instead of through it, so that uprights can be inserted from Side 4. Also wall loops are removed from LFCWP and LRCWP for the same reason (Fig. 5).

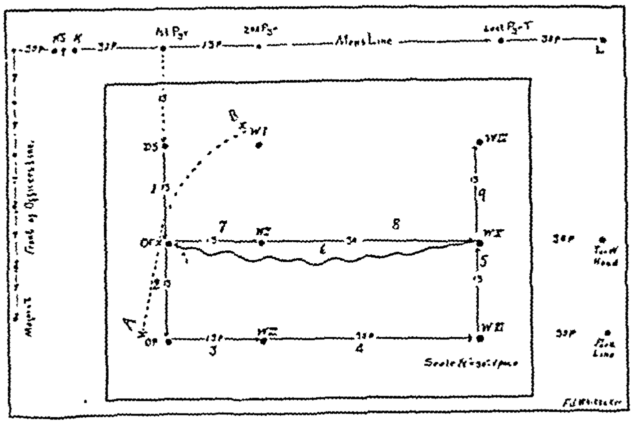

Fig. 15.—Laying out the hospital site: As soon as the officer has traveled over the route 1, 2, 3, 4, 5, 6, 7, 8, 9, the king pin sites for the hospital are located; the numbers 7, 13 and 30 refer to the number of paces; *x*, *x*, *x*, on the line *A-B*, the positions taken by the orderly; the dots, right front corner wall pins.

(*d*) Now the upright or uprights, and the ridge, hood and storm guys, if there are any, are inserted (Fig. 6). (The upright for pyramidal tents is inserted from the front door; uprights for all other rectangular tents from Side 4.) For all tents the front upright, hood, apex ring or square is numbered 1; the second, 2; the next 3, and the rear one 4, if there are so many.

(*e*) *Raising the Tent.*—For pyramidal tents: Each No. 1 of the four minor squads goes to his corner guy, and all No. 2's enter the tent and at command "Raise" by the NCO, raise the tripod and the wooden upright. The NCO at the door alines the upright. He directs the proper No. 1 to tighten. When he says "All tighten," all 1's and 2's tighten all guys and hood ropes on their respective sides. For hospital or wall tents: Minor squads 1 and 2 go to the front upright, and No. 1 of Minor Squad 1 places the apex of the upright on his right knee and adjusts the necessary parts. Minor Squads 3 and 4 do the same at the rear upright, No. 1 of Squad 3 assuming a left knee position. At the command "Raise" by the NCO, the tent is raised by the eight men. (Bases of uprights must always remain on the ground in the raising.) The same procedure is followed with the ward tent, except that Minor Squad 1 and No. 1 of Squad 2 raise Upright 1, No. 2 of Minor Squad 2 raises Upright 2, No. 2 of Minor Squad 3 raises Upright 3, and Minor Squad 4 and No. 1 of Minor Squad 3 raise Upright 4.

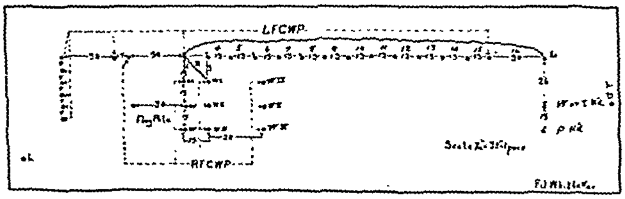

Fig. 16.—As soon as the officer has paced and meandered over the route 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, markers for officers', men's and kitchen tentage are in the ground. The numbers 7, 13 and 30 refer to the number of paces between pins; *RFCWP*, right front corner wall pin; *LFCWP*, left front corner wall pin; *O*, right or left front corner wall pin as shown above; *A*, men's and patients' latrines; *B*, wagon or truck park; *C*, picket line.

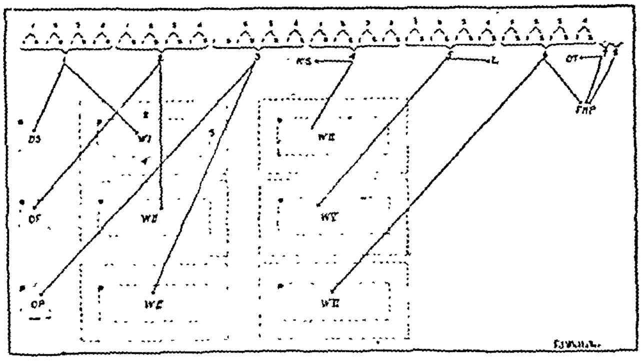

Fig. 17.—With an animal-drawn field hospital, the men form in line in the company street before pitching the field hospital.

(*f*) As soon as the tent is raised, the uprights are alined, all guys and other ropes are tightened, and all axes, extra pins and débris placed at the right front corner of the six ward tents (inside the ropes, axes chopped into ground in line, pins and débris in orderly piles). Figure 7 shows the method of placing tent, fly and storm guy ropes for the hospital tent.

STRIKING

Only four men strike a tent, as each squad usually strikes two tents. Minor Squads 1 and 2 strike their tent nearest the front of the hospital; Minor Squads 3 and 4 the tent toward the rear. First step: The guy

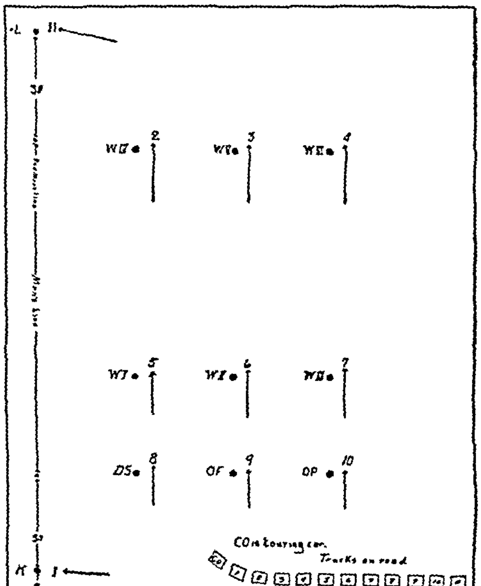

Fig. 18.—Route and stopping point of trucks: Each truck stops at the point on the hospital site where its number is placed. When unloaded, it goes at once to its proper place in the truck park, 7 feet apart. At truck park all drivers "eyes right" on office and Wards 2 and 5 markers for alinement.

ropes only on Sides 1 and 4 are loosened. (They are not taken off of the guy pins.) All wall loops are removed from the wall pins on Side 4 only (Fig. 8). Second step: The men go at once to the uprights (if there are two uprights, two men per upright; if four, one man per upright, in order of squad number from front to rear) and at the command "Down" by the man at the front upright, the bases of all uprights are removed through Side 4 (for pyramidal tents, through the front door; also wall loops on Side 4 need not be removed; Fig. 9).

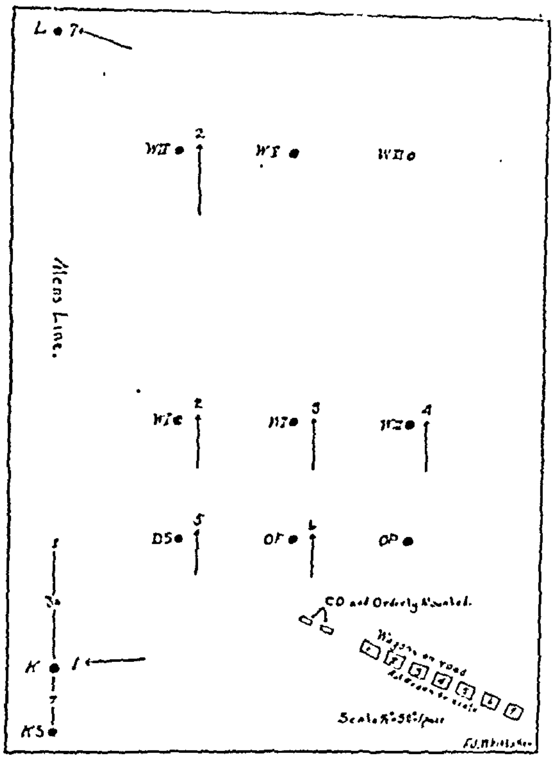

Fig. 19.—Route and stopping point of wagons: Each wagon stops at the point on the hospital site where its number is placed. When unloaded it goes at once to its proper place in the wagon park, 7 feet apart. At wagon park all drivers "eyes right" on office, and Wards 2 and 5 markers for alinement.

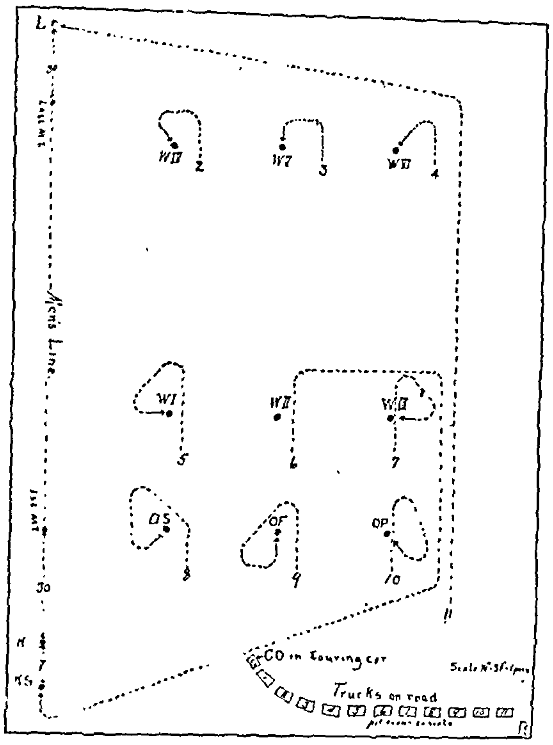

Fig. 20.—Pitching and striking at night. The commanding officer and orderly drive ahead of the column and place lighted lanterns at the marker site. Each truck stops at a lighted lantern as indicated in Figure 18. When unloaded it wheels and points headlights in direction of arrow. This gives a well illuminated field for pitching. These positions are assumed in striking also.

If the hospital is animal drawn the lanterns are placed as indicated, but the wagons stop as shown in Figure 19. The additional lanterns belonging to the field hospital are now lighted and placed wherever needed.

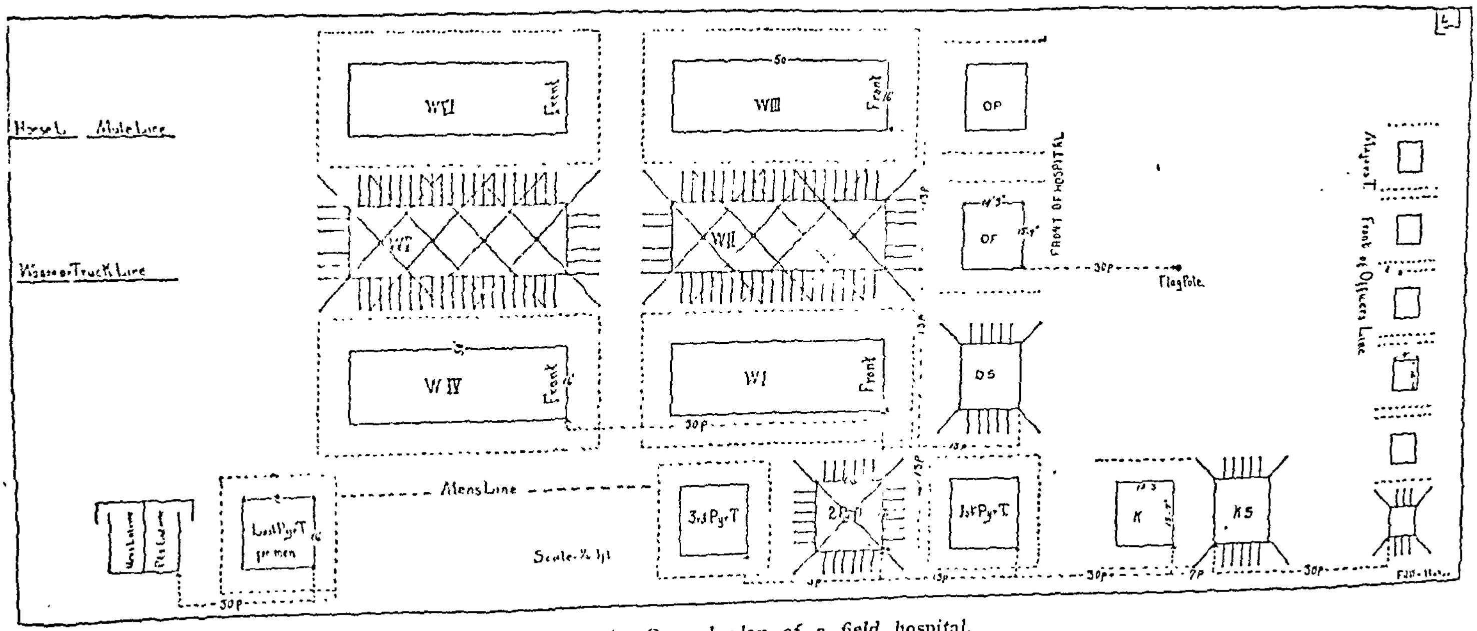

Fig. 21.—Ground plan of a field hospital.

FOLDING

All pins except RFCWP and RRCWP for all tents except pyramidal are removed. For pyramidal tents, all are removed except RRCWP and LRCWP. The tent is pulled away from its site until taut on the two pins left in the ground. Pyramidal tents are folded bellows-shaped (Fig. 14), and are folded from the apex the width of the metal square until all folded. Then they are folded from each end and tied with two center guy ropes, fully slackened. Hospital or wall tents are folded in end triangles until the tent is rectangular. They are folded from the apex in 2 foot folds until entirely folded. They are folded from each end and tied with two center guys, fully slackened. (If a fly is present, it is folded and the tent placed on it before final folding and tying. This ties both into one package.) With ward tents, the front of the tent, one panel beyond the first apex ring, is folded to the fifth loop (Fig. 10). The same is done at the rear (Fig. 11). Now eight storm guys and four hoods are added. Now from apex it is folded in 2 foot folds until entirely folded (Fig. 12). Rolling is begun at one end, and four guy ropes are left out, fully slackened, two on each side, at the other end for tying. This gives a drum-shape package easily handled, with only the wall outside (Fig. 13). Now it is tied in a cover or manta, if there is one.

LAYING OUT THE HOSPITAL

As soon as the officer has traveled over the route 1, 2, 3, 4, 5, 6, 7, 8, 9 (Fig. 15), the sites for the store tent, office, operating tent and six ward tents are located. If pyramidal tents for the men are to be pitched, sites are marked as in Figure 16. If shelter tents, when he is ready to leave Ward 4 marker, the officer continues outward for 13 paces and places a marker to orient the rear end of the men's line. This marker is in line with Wards 4, 5 and 6 markers. He then goes to the stores marker, moves outward for 13 paces, and places a marker in line with stores, office and OP tent markers to mark the head of the men's line. At this marker he right angles to the left for 30 paces and places a marker for RFCWP of the kitchen. This marker is in line with the front and the rear men's markers. At 7 paces farther in the same line, he places a marker for the LFCWP of the kitchen store tent. He then continues in the same line for 30 paces, and places a marker for the LFCWP of the junior officer's tent. He right angles to the left, goes 7 paces, and places a marker for the LFCWP of the next officer's tent, 7 paces more for the LFCWP of the next officer's tent, and so on until a marker for the major's tent is placed.

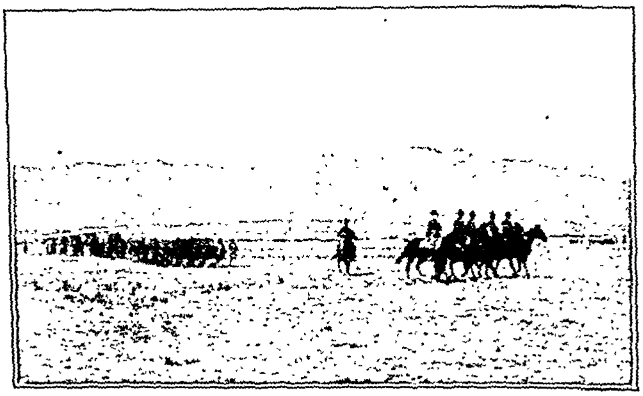

Fig. 22.—An animal-drawn field hospital on the march.

Route of Orderly (*A-B*, Fig. 15).—The orderly starts at OP tent by assisting the officer in turning a right angle and waving him into position at Ward 3. He then goes to a point in front of the office marker and alines the officer for Ward 2 marker. He then goes to a point near the site for Ward 1 marker and places a marker in the ground alined on Wards 2 and 3. The officer at Ward 4 also alines the orderly's marker on Ward 4 and stores, which locates the site of Ward 1 marker.

Waving into Position.—The waver extends both arms sideward, looking at the "marker or pin setter." "M or PS" moves the marker or the pin to the right or to the left as the right or the left arm of the waver moves up and down. Both arms of the waver quickly lowered means "position is correct."

Provisional Pin.—When the officer first reaches Ward 5 he places a marker slanting directly backward as a "sighting" or provisional marker. Its distance from Ward 6 marker is correct, but its distance from Ward 2 marker is uncertain. The orderly at the office waves the officer into position at Ward 2 by sighting on a slanting marker, and the officer "ties in" this marker (places it in proper position perfectly upright) after pacing "8" (distance between Ward 2 and 5 markers) in the route of the officer.

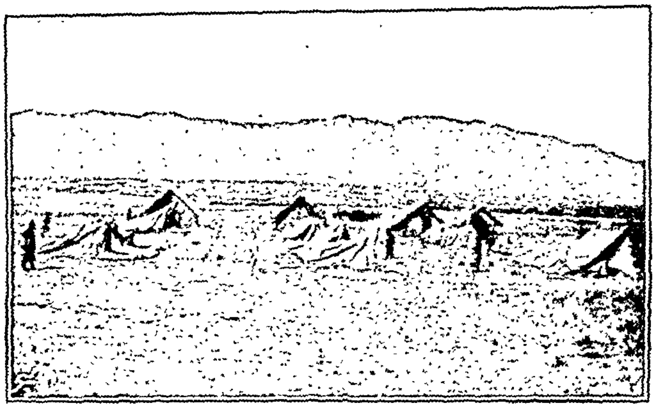

Fig. 23.—Raising the hospital tentage.

TO FORM COMPANY ON LINE FOR PITCHING HOSPITAL

The company approaches in column of fours at double time with the leading element facing directly down CF line. The commands "On right into line," and "March" are given as the first set of fours reaches the head of the men's line, and "Company, Halt" as soon as on CF line; "Front," as soon as the company is in proper line 13 paces from hospital site; next, "Count Twos"; then "Count MS by fours" (this means count minor squads 1, 2, 3, 4; 1, 2, 3, 4; 1, 2, 3, 4, and so on, each No. 2 counting). Then the command "Count TP Squads." (Each No. 2 of each fourth minor squad counts numerically as 1, 2, 3, 4, 5, 6, etc.). As soon as this count is completed, the men rush to the wagons, unload and pitch the hospital. For the *motorized field hospital*, proper squads are already on trucks at the proper tent pitching sites. As soon as they have unloaded the trucks they rush to the men's line, unsling packs, return to tent sites, and begin pitching.

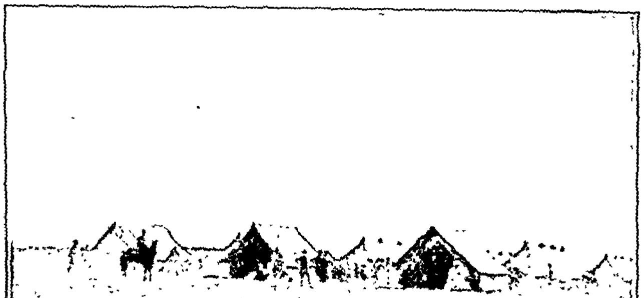

Fig. 24.—The hospital complete, ready to accommodate 216 bed patients.

ABBREVIATIONS

MS, minor squad
CF, company front
TPS, tent pitching squad
L, latrine
DS, dispensary and stores tent
OF, office tent
OP, operating tent
FHP, field hospital property
MS by fours, minor squads by fours
TP Squads, tent pitching squads

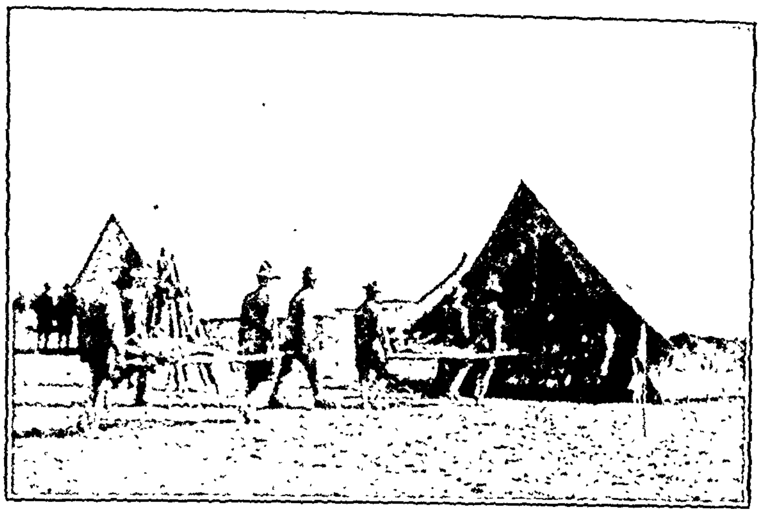

Fig. 25.—Admitting patients to the hospital.

Two cooks and two kitchen police riding on Truck 1 pitch the kitchen fly.

ROUTINE

When an order to pitch hospital is received, an officer with an orderly seeks a suitable site and lays out the hospital as in Figure 15. If this order occurs at night, the procedure is outlined in Figure 20. Later the officers' line is added as in Figure 16. When trucks or wagons arrive, they go to sites as shown in Figures 18 or 19. Tentage is pitched as in the large ground plan.

ABBREVIATIONS

K, kitchen
KS, kitchen stores
OT, officers' tentage
W, ward
OF, office tent
OP, operating tent
FHP, field hospital property
SQ, squad
KP, kitchen police
DS, dispensary and store tent
L, latrine tentage
HT, hospital tent

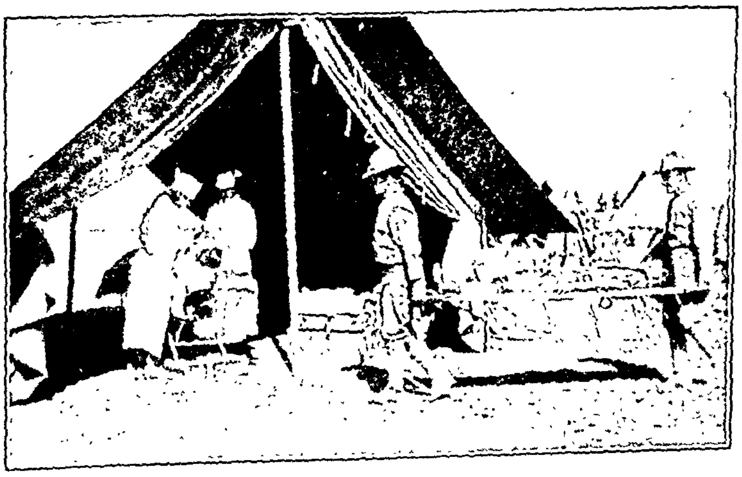

Fig. 26.—A view of the operating tent.

LOADS OF TRUCKS

Truck 1 carries K. fly; KS; OT; KS tent; cooks and KP.
Truck 2 carries W 4 complete; FHP; Sq. 4.
Truck 3 carries W 5 complete; FHP; Sq. 5.
Truck 4 carries W 6 complete; FHP; Sq. 6.
Truck 5 carries W 1 complete; DS; FHP; Sq. 1.
Truck 6 carries W 2 complete; OF; FHP; Sq. 2.
Truck 7 carries W 3 complete; OP; FHP; Sq. 3.
Truck 8 carries Disp. equip.; FHP; Sq. 7.
Truck 9 carries Office equip.; FHP; Sq. 8.
Truck 10 carries Oper. tent equip.; FHP; any extra men.
Truck 11 carries FHP; L; gas; oil; water; any extra men.

LOADS OF WAGONS

Wagon 1 carries same as Truck 1. (Codks and KP ride wherever convenient.)
Wagon 2 carries 6 Ward tents (no poles or pins).
Wagon 3 carries 3 HT—all poles, pins, axes.
Wagon 4 carries Bedding.
Wagon 5 carries Bedding, Disp. Office and other FHP.
Wagon 6 carries OP equip. and FHP.
Wagon 7 carries L and forage.

SQUAD DUTY

Each squad always unloads, pitches, strikes and loads tentage and equipment as follows:

Sq. 1 = DS and W 1
Sq. 2 = OF and W 2
Sq. 3 = OP and W 3
Sq. 4 = KS and W 4
Sq. 5 = L and W 5
Sq. 6 = W 6 and places FHP
Sq. 7 = Places FHP and pitches OT
Sq. 8 = Places FHP

Cooks and KP pitch the kitchen fly, put up a stove, dig a garbage pit, and prepare a meal.

All police the camp site before leaving. The hospital should be laid out before the arrival of trucks or wagons in order to avoid delay.

PITCHING AND STRIKING A FIELD HOSPITAL

Time begins when wagons or trucks are 50 feet from the hospital site (the ground plan is given in Figure 21). If the equipment is animal drawn, the men double time to the men's line, remove packs, rush to the proper wagons (Fig. 17), unload, and pitch tents as indicated under "routine." If the equipment is motorized, when the trucks stop at the tent sites the men jump off, unload the trucks, rush to the men's line, remove equipment, rush back to the tentage sites, and pitch the proper tents. Time ends when every detail previously announced by the commanding officer is completed. (At first drills, only tent pitching is done. Later, latrine, wagon or truck park, kitchen, equiping one ward, office, operating tent, picket line, if there is one, are added. Finally, the hospital complete in every detail is required.)

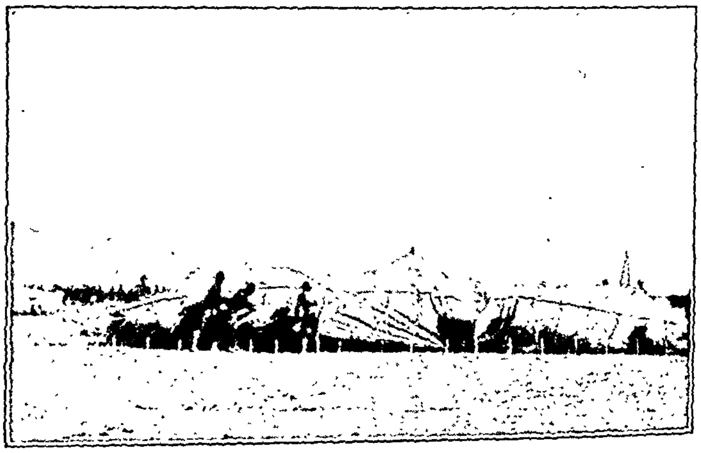

Fig. 27.—Striking the huge ward tent; each field hospital has six of these.

Striking.—Men form in line in the company street. The whistle blows. Time begins. The men rush to work. Time ends when the equipment is properly loaded, and men and vehicles are 50 feet beyond the hospital site. (The site, of course, is to be policed perfectly.)

FOR SPEED IN PITCHING AND STRIKING HOSPITAL

All details should be so arranged that *no commands* are needed at the hospital site. With a well trained company *no voices* are heard during pitching or striking. If time is taken, a whistle blast starts and ends each operation.

Although it has taken many words and illustrations to present the details of pitching and striking a field hospital, a trained field hospital company has pitched its field hospital, ready for work, in less than fifteen minutes. Also it has struck the hospital and been en route to some other field of endeavor in six minutes.

MEDICOMILITARY CONSIDERATIONS OF THE MODERN MILITARY BULLET

ROBERT BOOTH ACKER, M.D.
Assistant Surgeon, United States Public Health Service
FORT STANTON, N. M.

The modern military bullet is small of caliber, of comparatively light weight and is propelled at very high velocity by dense smokeless powder. It is sharp pointed and is cylindro-ogival in shape. The bullet consists, in most cases, of a central core of lead with an extremely hard jacket of nickel composition. The French bullet, however, is of solid copper.

From the short, heavy, large-calibered bullet of lead, propelled at low velocity by black powder, the military bullet has changed, through many gradations, to a long, light-weight, small-calibered jacketed bullet, propelled at very high velocity, with flat trajectory, by smokeless powder and with a striking force of tremendous energy.

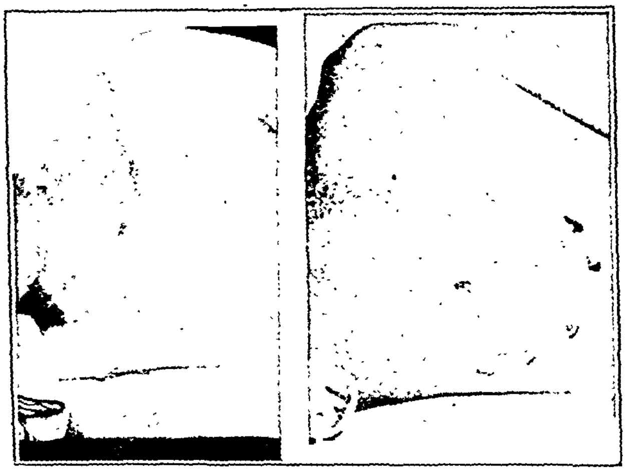

Fig. 1.—Simple perforation with minimum tissue injury. Result of a sniper's bullet at long range.

It was originally believed that a bullet of this type, if it did not strike a vital part, would cause a simple perforating wound which would heal quickly and cleanly. Practical experience has shown that the modern military bullet commonly causes wounds of an extensive and mutilating character, especially at moderate ranges and on striking bone. This destructive action is popularly known as the "explosive effect," and indeed a penetrating bullet in the act of leaving the body may literally tear away the flesh or leave a mushroom-like mass of tissue at its point of exit.

As an instrument of death and as a means of producing wounds of a severe and disabling character, the modern bullet is very effective. It is at long ranges that the simple perforating effect is most often noted.

The German S bullet (*Spitzgeschoss*) weighs 154 grains and is propelled by approximately 50 grains of dense smokeless powder. The jacket is of ferronickel. The lead core is not completely covered by the jacket but is exposed at the base of the bullet. The English bullet is similar in construction, with a jacket of cupronickel and an aluminum cone or so-called "jockey" at the point of the lead core. It is longer and heavier than the S bullet and weighs 174 grains. The French bullet is of solid copper, and is longer and heavier than either the German or the English bullet, its weight being 197 grains. The 1906 United States government model Springfield cartridge has a bullet weighing 150 grains, with a lead core and a jacket of cupronickel.

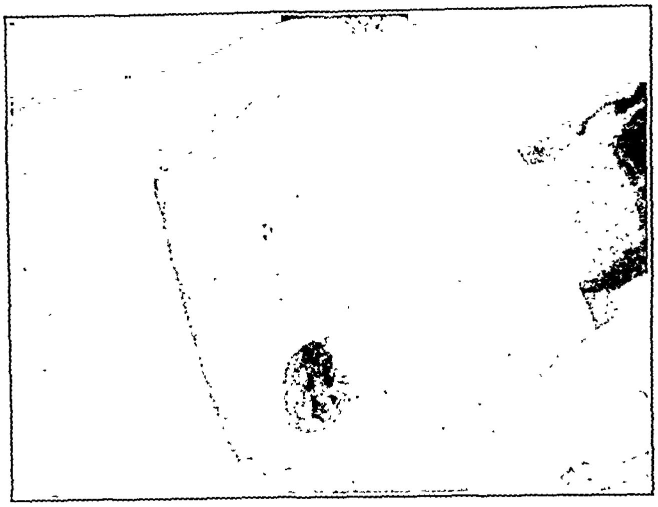

Fig. 2.—Explosive wound of exit in muscles of the back, produced by a bullet at range of less than 500 yards.

The German cartridge is the most powerful in use among the belligerents at the present time. The bullet leaves the muzzle of the rifle with a velocity of 2,915 feet per second and has at the muzzle a striking energy of 3,018 foot-pounds, or two and one-half times that of the old 45-70 U. S. Springfield cartridge used in late Civil War days. The 1906 Springfield cartridge most nearly approaches this tremendous force, having an initial velocity of 2,700 foot-seconds and a muzzle energy of 2,445 foot-pounds. The velocity, and consequently the striking power of these high power bullets, rapidly falls after traversing the first few hundred yards, so that at 500 yards the velocity of the German bullet is 1,714 foot-seconds and its striking energy but 1,001 foot-pounds, only one third of its muzzle energy, while the Springfield bullet is traveling at the rate of 1,668 foot-seconds and has only 932 foot-pounds energy. At 1,000 yards the velocity and energy of each is 1,068, 382 and 1,047, 370, respectively.

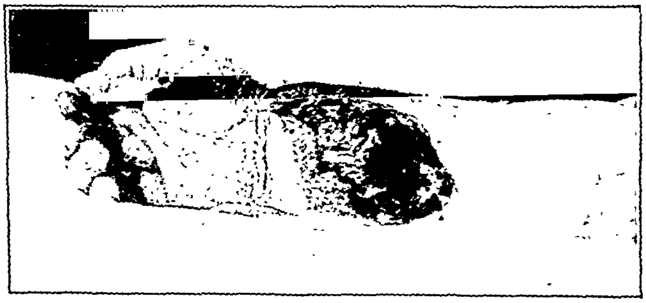

Fig. 3.—Extensive tissue destruction produced by a high energy, penetrating bullet striking the ulna and causing comminution. Range less than 500 yards. A roentgenogram of this wound is shown in Figure 4.

The velocity and striking force of these two bullets decreases much more rapidly, relatively, than is the case with the French and English bullets, which have a lower initial velocity but higher sectional density and weight. Thus the English and French bullets, especially the French, are much more effective at extreme ranges, for, while they do not start with as much energy, their greater mass assists in its retention. It is obvious, however, that all of these bullets are at the height of their energy and destructiveness before the first 500 yards are passed in their flight.

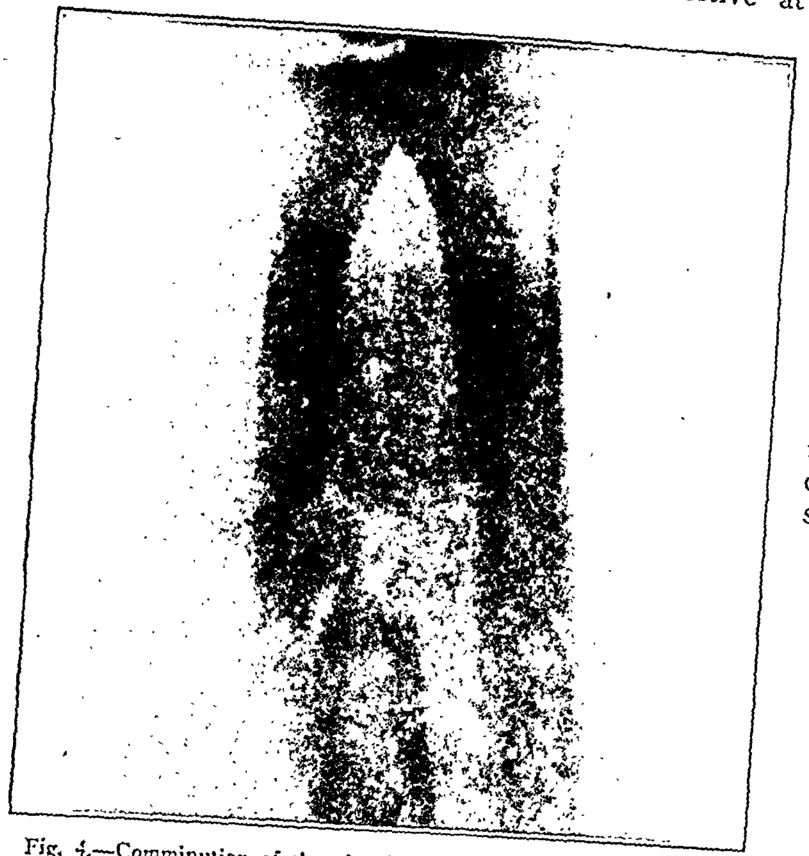

Fig. 4.—Comminution of the ulna in the wound shown in Figure 3.

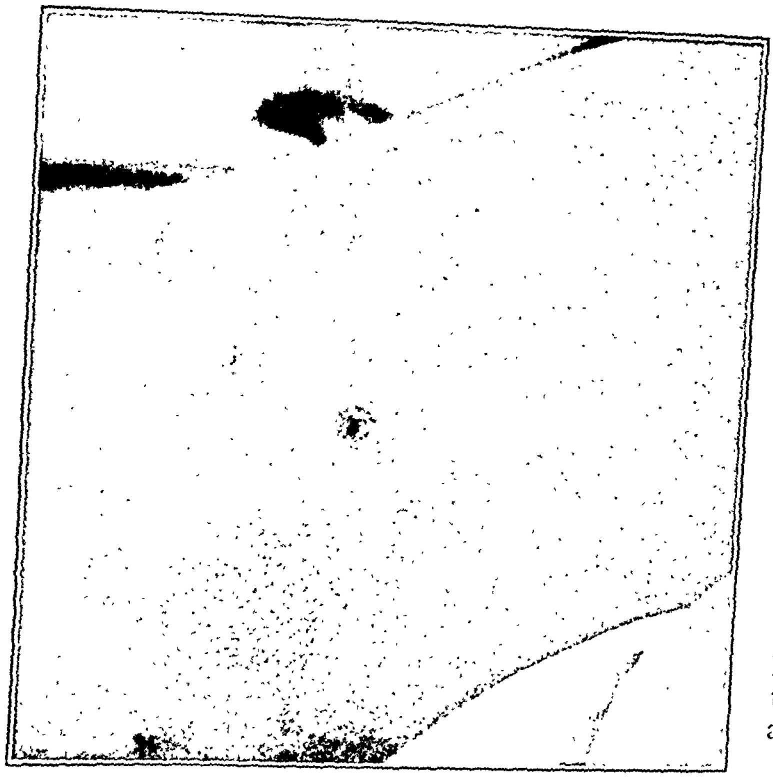

Fig. 5.—Simple wound of entrance made by a bullet that lodged in the thigh. Range over 500 yards.

The construction of the German bullet, and others of like type, renders it liable to fragmentation on striking hard objects. This fragmentation is of varied form. The jacket is generally stripped off in one piece and curled, although it may be broken into several pieces. The lead core may remain in one battered lump, may be divided into a few large pieces, or may be shattered into fine pellets, or even into a dustlike condition. The stripped jacket may be left behind in the tissues by a perforating bullet. The solid French bullet, while it may be deformed by striking a hard object, rarely if ever undergoes fragmentation. "Explosive bullets," as these are sometimes called, have, in many instances, had their velocity checked and their course altered by striking an intervening object. They ricochet, and the fragmentation begun by the first impact is completed by striking the body. They do not commonly produce the severe laceration of a penetrating, intact bullet at the height of its energy.

A jacketed bullet may, in traversing a barrel heated by repeated firing and aided by the friction of the particular bullet, become heated to the extent that the lead core assumes a semisolid state. Such a bullet when it strikes, flattens out like a well-rotted apple, and the lead is distributed in the tissues in a finely powdered form. A bullet of this nature would have little penetration and its destructiveness would be thereby limited.

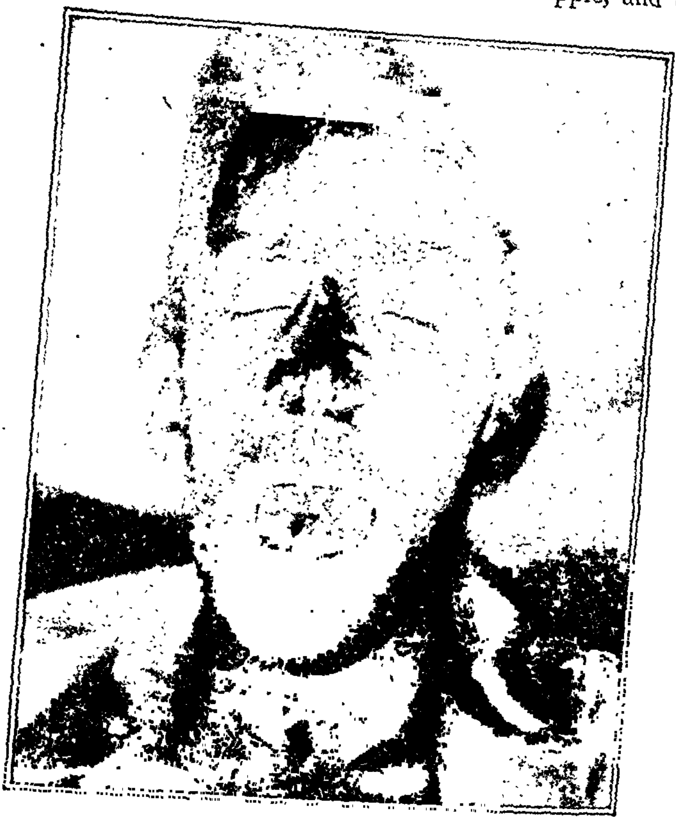

Fig. 6.—An unusual bullet wound. Sniper's shot at long range. Bullet entered at the bridge of the nose, penetrated the nasal fossa, hard palate and tongue and lodged in the tissues of the neck near the larynx. Patient recovered.

It has been repeatedly noted by medical officers that at moderate ranges the military bullet produces extensive and destructive wounds in its course of leaving the body. At longer ranges the bullet is more apt to lodge with less destructive effect, or simply to penetrate with little or none of the "explosive effect" noted at closer range.

In the matter of the bullet itself there are two factors concerned in the production of the maximum mutilation of tissue: *the high velocity of the bullet, and its power of penetration.* As previously shown, a light-weight bullet, such as the German bullet, must move with great velocity to develop such tremendous energy. Any factor reducing the velocity diminishes the energy. In flight the velocity decreases rapidly, and the energy much more rapidily, so that at 500 yards the energy is only one third of the muzzle energy; hence, it is only in the first few hundred yards of its flight that penetration with great energy is produced.

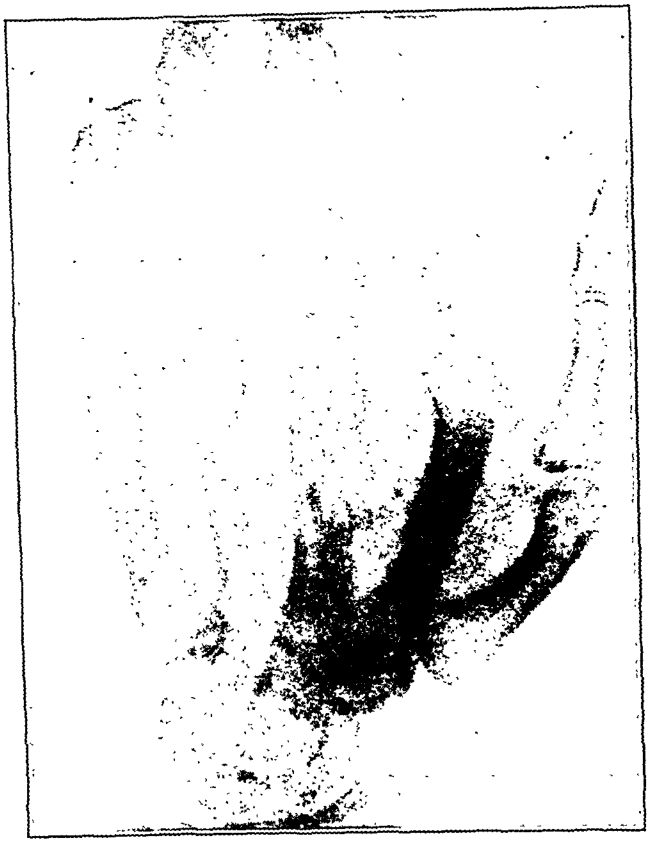

Fig. 7.—Comminution of the metacarpal bones with explosive effect of the bullet in the palm of the hand.

It is this penetrating bullet of high energy that produces the maximum destruction of tissue. The large mutilating, explosive wounds are wounds of exit, the entrance wounds being uniformly small. The most extensive wounds of this character are produced when the shaft of a bone is shattered and the fragments are driven out in the bullet's path.

The wound shown in Figures 3 and 4 was produced in just this way. A high velocity bullet entered the arm on the dorsal surface. The ulna was badly comminuted and fragments of the bone were driven out, literally tearing away the flesh.

In general, it may be said that the closer the range the less likely the bullet is to remain in the tissues and the more likely it is to produce the "explosive effect." It is within the first 500 yards that the "explosive effect" is most often produced.

A bullet on leaving the rifle barrel has two motions: forward motion in the line of flight, and a twisting motion on its longitudinal axis, imparted to it by the rifling of the bore. It is traveling at its maximum velocity and with least air resistance when only these motions are retained. In its flight it may acquire a third motion, a revolving or tumbling on its transverse axis, which, if it comes to pass, markedly slows the bullet and lessens its striking energy.

The turning of a bullet base foremost in the cartridge case reduces the accuracy of its fire, and, as it would travel with greatly diminished velocity, it is much less dangerous and much less destructive to tissue than a bullet in the proper position. The popular belief in the "dum-dum" action of a bullet of this nature is a fallacy.

SUMMARY

The modern military bullet is a projectile, composed in most cases of a lead core with a nickel jacket. It is of low weight, increased length, small caliber and is propelled at very high velocity by dense smokeless powder. It has a flat trajectory and develops tremendous striking energy.

COMPARATIVE BALLISTICS OF MILITARY CARTRIDGES IN USE BY THE BELLIGERENTS IN THE PRESENT WAR

Country	Name of Arm	Caliber (Inches)	Weight of Bullet (grains)	Jacket of Bullet	Core of Bullet	Muzzle Velocity, Feet per Second	Muzzle Energy, Foot-Pounds
France..........	Lebel........	.315	197	None	Solid copper bullet	2,296	2,305
England..........	Lee-Enfield (mark VII cartridge)	.303	174	Cupro-nickel	Lead	2,450	2,320
Germany.........	Mauser.......	.311	154	Ferro-nickel	Lead	2,915	3,018
Russia..........	Nagant, 3 line	.30	214	Ferro-nickel	Lead	1,985	1,862
Austria, Bulgaria and Greece	Mannlicher...	.315	244	Ferro-nickel	Lead	2,034	2,240
Belgium..........	Mauser.......	.301	219	Ferro-nickel	Lead	2,034	2,010
United States.....	Springfield, Model 1906	.30	150	Cupro-nickel	Lead	2,700	2,445
Italy.............	Paravicini-Carcano	.256	163	Ferro-nickel	Lead	2,295	1,891
Roumania........	Mannlicher...	.256	162	Ferro-nickel	Lead	2,400	2,070
Turkey..........	Mauser.......	.301	211.3	Ferro-nickel	Lead	2,066	2,003

The velocity, and consequently the energy, of this projectile decreases rapidly after the first few hundred yards of its flight.

It is at its highest energy before passing the 500 yard mark; hence, destructive and mutilating wounds are most commonly produced inside this range.

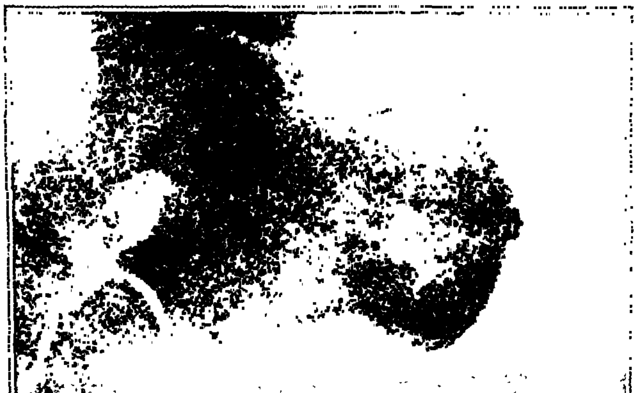

Fig. 8.—Penetration of the os calcis by a high energy bullet at close range but with little comminution or tissue destruction.

These destructive or explosive wounds are wounds produced at the exit of a bullet of very high energy.

At longer ranges the tissue destruction is much less, and a simple perforation may result.

ACCLIMATIZATION TO THE TROPICAL SUN

Although our knowledge of the regulation of body temperature and its relation to metabolism has reached a stage at which an intelligent appreciation of many of the factors involved can be formulated, there are features of the heat-controlling mechanism that still demand elucidation. In several respects the climatic conditions that prevail in the tropics have furnished greater obstacles to the comfort of man than have the severe rigors of arctic surroundings. The problems of climatology in the tropics have become emphasized by the growing necessity of the white man's residing there and adjusting himself to the situations created by wind and weather. By some writers, tropical sunlight has been endowed with properties peculiarly detrimental to human health and comfort. The effect of the ultraviolet rays on the skin in the familiar production of the inflammation called sunburn, erythema solare, is not directly associated with heat. Indeed, it is often said to be more likely to occur in colder surroundings, owing, in part perhaps, to the fact that the heat of the sun's rays is not noticed, so that means are not taken to protect the skin to the same extent from their action.

Several years ago Aron, then professor of physiology in the College of Medicine and Surgery at Manila, reported an almost surprising series of observations on the susceptibility of the monkey, a tropical animal, to harm from direct exposure to the sun in the Philippines. Animals were reported to die in many cases in from seventy to eighty minutes when placed on the ground in the Manila sun, even in the coolest months of the year.[1] Shaklee,[2] pharmacologist at the University of the Philippines, has verified the observation that unclimatized Philippine monkeys exposed to the sun in Manila may die of heat stroke in the course of a very short time, depending on conditions.

Factors that must be taken into account in any attempt to determine the cause of a rise in body temperature or of death following exposure to the sun are the energy of the solar rays, and the temperature, the movement and the humidity of the air. Shaklee finds by direct observations that the conditions making for a rapid death are a hot sun; proximity of a large hot surface, such as the ground or a roof; high relative humidity of the atmosphere, and a low wind velocity. Under such circumstances death is due to an accumulation of heat in the body.

The novelty in Shaklee's studies is the finding that monkeys can apparently be acclimatized to the conditions mentioned, if exposure to them is gradual. This is of signal importance in relation to the comparable possibilities in the case of man; for the human organism seems in many ways far better adapted than the monkey's to resist the tropical climate. Shaklee points out that the temperature-regulating mechanism in man is much more sensitive than that in the monkey, as shown by the smallness of the normal variation of the body temperature in man as compared with that in the monkey. The sweating mechanism in man has many times the capacity of that in the monkey, and as the temperature of the surrounding atmosphere approaches the temperature of the body, this becomes the most important means of eliminating heat from the body. The internal heat production of man on a light diet is smaller in proportion to body surface than that of the monkeys subjected to this experiment. Man stands higher above the hot surface on which he rests or moves; hence he would receive less heat from the ground and be subjected to a more rapid movement of air over the body surface than would the monkey. Man's body has much less hair than the monkey's; hence the escape of heat from his body by radiation, conduction or evaporation is less interfered with. Man can so select and arrange his clothing that it will interfere little with the escape of heat from his body, while at the same time it will shield the body from the heat rays coming from the sun. Moreover, man is acquainted with a larger variety of foods.

The acclimatization to the tropical climate as experimentally accomplished in the case of the monkey appears to be due essentially to an increase in the sensitiveness of the nervous mechanism that regulates body temperature. This results in an increase in the rate or efficiency of sweating, producing what has perhaps falsely been termed an immunity. The "immunity" is readily lost if the subjects are kept in the shade. In harmony with the explanation advanced above is the fact that a small dose of atropin, which diminishes the action of the sweat glands, as well as other secretory structures, suffices to nullify the effect of any acclimatization and to cause the death of an acclimatized animal by stopping perspiration. The inference is further supported by the fact that when the relative humidity of the atmosphere is great, even acclimatized animals exhibit a tendency to a markedly greater rise in body temperature. Finally, attempts to acclimatize rabbits—a species not known to perspire—have thus far entirely failed.

---

[2] Shaklee, A. O.: Experimental Acclimatization to the Tropical Sun, Philippine Jour. Sc., (B), 1917, 12, 1.

Evidence has begun to accumulate that healthy white men may be readily acclimatized to the tropical climate at its worst. Shaklee maintains that the amount of sweating necessary to keep the body temperature of a healthy white man from rising above normal is not excessive, even when the man is doing considerable physical work in the midday sun in such a tropical climate as that of Manila, provided the man has been sufficiently long on a suitable diet and introduces himself gradually into the work in the sun. In the acclimatization of the white man the most important factor is the proper regulation of the diet. The effects from the tropical sun seem to be exactly the same as the effects from the sun in the United States; that is, no effects were seen or felt in these experiments that were different from what would have been expected under like circumstances in the northern portion of the United States.

THE STRENGTH OF DIABETICS

Although a person in the diabetic condition may be excreting valuable sources of energy, in the form of sugar and ketone substances derived from incompletely burned nutrients, there is no decrease in the quantities of energy transformed in contrast with a comparably healthy individual. There is merely an alteration in the source of the energy; for when carbohydrates can no longer be satisfactorily metabolized, other foodstuffs must be drawn on to supply the body's inevitable needs. Few diabetics can tolerate as much food as their former needs indicate to be essential. The modern starvation treatment of diabetes in the form advised by Allen, which introduces a rigorous regimen of fasting until the diabetic patient becomes free from urinary glucose and from acidosis, meets the energy problem in a direct way. The resulting emaciation apparently decreases the amount of active tissue substance. Calorimetric observations have shown that if a person whose metabolism is normal has been reduced in weight by 30 per cent., his metabolism when he is fed on a low dietary may also be reduced far below his normal level measured by his original weight or body surface. In other words, a smaller body can suffice with a small total intake of food. Emaciation may reduce the body to a size at which it can develop tolerance for the smaller requisite food quota.

Since in ultimate analysis the energy for muscular work comes from energy in the form of ingested food, the question has repeatedly arisen, What effect does the persistent use of a low diet have on the physical vigor of the diabetic? Muscular weakness is characteristic of the diabetic. What bearing has underfeeding on this feature in the case of patients obliged to subsist on a small allowance of food? The answer to this inquiry has been sought by Williams,[1] in a study of the influence of low diets, or the Allen method of treatment, on the physical vigor of diabetics. Strength tests were made by the use of the Collin dynamometer. It appears from the results, and in accord with common clinical observation, that diabetics, as a rule, are distinctly physically weaker than normal persons. Loss of body musculature may partly explain this, but it is probable that the lessened amount of food metabolized in these patients does not provide sufficient energy for the normal exercise requirements of the body. There appears to be a direct relationship between food tolerance and muscular vigor. As food tolerance increases, so does also muscular tone. Decline in food tolerance is accompanied by loss of physical vigor.

Williams further maintains that the continued use of a low diet for many months, even though it falls far short of the energy requirements of the body, provided it is within the physiologic limitations of the body to metabolize it, will cause an appreciable gain in muscular tone, although the amount of physical effort that such a person may be able to put forth may be considerably below the normal. This is in accord with clinical experience that nutrition within the tolerance of the patient gives the greatest comfort, strength and sense of well-being and, as Joslin has pointed out, the greatest expectation of life.

It is not long since the practice was common to urge the feeding of diabetics as freely as possible, in the hope of averting a loss of strength by promoting the greatest possible gain in weight. The new observations of Williams indicate that while diabetics living on a diet below normal physiologic requirements possess a diminished muscular vigor, feeding them beyond their metabolic limitations causes not only a further reduction in their tolerance for food, but also an even greater loss of strength. Thus the hope of improving a bad situation in such cases by overfeeding may well be abandoned.

THE ACTIVE PRINCIPLE OF THE HYPOPHYSIS

The physician who is not extremely well versed in the modern biochemistry of animal tissues might easily draw the conclusion from clinical literature, particularly of the advertising sort, that the "active principles" of various glands and secretions are definitely known and readily isolated. The fortunate circumstances of the separation and complete identification of such a substance in the case of the epinephrin of the suprarenals has given the impetus for further attempts of the same sort. Names have not been lacking for the anticipated "principles"; and occasionally a proposed designation has crept into print in advance of any bona fide production of a truly corresponding active substance. It need not be denied that extracts and other preparations of glands have been prepared in a state of pronounced physiologic potency and corresponding therapeutic value. But this is something as remote from the production of a chemically defined compound of recognized composition as is the isolation of the crystalline alkaloid morphin from gum opium.

---

[1] Williams, J. R.: The Effect of Undernutrition on Muscular Force: A Study of the Influence of Low Diets, or the Allen Method of Treatment on the Physical Vigor of Diabetics, Arch. Int. Med., September, 1917, p. 399.

Attention has been called by Abel and Pincoffs[1] to misleading claims or beliefs of the sort just indicated, in relation to preparations of "active principles" of the pituitary gland. Thus one widely heralded product claimed by its sponsor to be a "solution of the isolated active substances of the pituitary gland," far from being a mixture of crystalline compounds of high physiologic activity which would justify a designation indicative of chemical unity, is shown to be at best a mixture of proteoses (and possibly peptones) with varying and unknown amounts of active and inactive constituents of the glands.

A study of various commercial pituitary preparations in the laboratory of the Baltimore investigators showed that secondary proteoses and possibly peptones (or polypeptids, if the term is preferred) were present in all of the therapeutically used extracts of the posterior lobe of the hypophysis cerebri that were examined. To what extent the proteose content of the gland may have been increased by autolysis or by processes incidental to the manufacture of the extracts it is impossible to state. It is believed, nevertheless, that the perfectly fresh, bloodless glands yield proteoses, since Abel and Pincoffs have actually isolated such substances from the thyroid gland and other organs when taken from the animal immediately after it has been bled to death.

It would be unfair to assert that every producer of pituitary commercial extracts claims to offer a product free from protein and containing absolutely nothing but potent gland constituents. As a matter of fact, however, those examined do contain adventitious substances. In answer to the inquiry naturally provoked by these findings, Abel and Pincoffs have found that the proteoses isolated from pituitary extracts are practically devoid of oxytocic or uterine contracting action. These protein substances do not constitute the "motiline"[2] that effects the well known activity of suitable pituitary extracts as uterine stimulants.

According to Abel and Pincoffs, and contrary to current teaching, proteoses are present in more than one tissue of the body. Proofs of their existence in gastric and intestinal extracts also has been obtained. The isolation of the hormones found in various active tissues will require a preliminary removal of the proteoses — a task of considerable technical difficulty. Abel and Pincoffs have been able to prepare an extract of the gastric and intestinal mucosa which has a pressor action for the circulation and a marked oxytocic power in a concentration of 1 : 1,000,000. This powerful action points strongly to the conclusion that here also, as in the case of pituitary extracts, we are dealing with a motiline which, in a state of chemical purity, would be fully as active as beta-imidoazolylethylamin. And this again leads to the supposition that the oxytocic principle (or motiline) of the hypophysis is not a hormone or substance specific to this organ, but is rather a widely distributed substance, everywhere the same, which may have its origin in the various tissues, in the gastric or intestinal mucosa, or which may be absorbed as such from among the products of digestion. In any event, we may well agree with the Johns Hopkins pharmacologists that the active principles of the hypophysis cerebri have not yet been isolated as chemical individuals.

---

[2] This word has been coined in evident analogy with "secretine," the hormone which promotes *flow* of secretions, to indicate a contraction-producing hormone.

FRUIT ACIDS

Although fruits are held by some persons to be a luxury rather than a dietary necessity, they have recently come into a greater popularity than ever before in the ration of man. The typical American breakfast provides for fruits of some sort as a part of the menu. They enter likewise into the larger meals of the day, and thus secure prominence whether it be because they are regarded as stimulating to the appetite, as endowed with laxative properties, as sources of actual nutriment, or merely as adding a pleasing variety to the diet regardless of any unique dietary virtues. Almost all fruits contain sugar. Experts in nutrition at the present time are inclined to assert that fresh fruits and vegetables, although watery, are convenient sources of many of the substances which are needed by the body in small amounts. Quoting a government publication,[1] it is, in fact, generally believed that, unless these foods are used to some extent, the diet will be lacking in mineral materials and in other important growth and health promoting substances. They are, however, not important sources of fuel. They contain little protein and no fat. The evidence of the extent to which fruits are used lies in the fact that the crop is valued at considerably over 200 million dollars, of which the major share belongs to the orchard fruits. Nearly 200 million bushels of apples alone are produced in the United States each year.

All of the fruits contain noticeable amounts of organic acids, varying with the species involved. As a general rule the acidity tends to decrease with the progress of the ripening. The nature of the acids present has hitherto been anything but accurately determined. In a general way it has been the custom in some quarters to distinguish between highly acid and "subacid" varieties—distinctions of a quantitative rather than a qualitative character. The acidity of fruits is said to be largely due, not to free acids, but to acid salts, of which the acid potassium tartrate (cream of tartar) of grapes may serve as an example.[2] However, more than an incidental interest attaches to these questions. Not only may different acids have unlike rôles in promoting some of the effects, such as laxative action, now vaguely assigned to fruits; but there is reason to believe that some of the fruit acids, such as tartaric and benzoic, are oxidized with difficulty if at all in the body. The more readily burned fruit acids act to promote potential alkalinity; for when the organic radicals are oxidized to carbon dioxid and water, so much of any base as was combined with the organic acid remains as a carbonate. Thus, contrary to the popular belief, in metabolism most of the acid fruits actually function as base-forming foods. In accord with this the use of fruits tends to diminish the acidity of the urine, except in those cases in which, owing to incomplete oxidation of the fruit-acid in the system, the potential alkalinity is not fully realized. Blatherwick[3] found, for example, that such foods as oranges, raisins, apples and bananas are very efficient in reducing the acid output. A further importance of the fruit acids is associated with the part they play in jelly making.

---

[1] Hunt, Caroline L.: Fresh Fruits and Vegetables as Conservers of Other Staple Foods, U. S. Dept. Agr., Farmers' Bull. 871, July, 1917.

The Bureau of Chemistry of the United States Department of Agriculture has undertaken a critical investigation of the acid content of fruits. The chemists, Bigelow and Dunbar,[4] state that the burden of evidence in the literature indicates that tartaric acid is not an ingredient of fruit juices except, of course, grape juice. Citric and malic acids are the characteristic acids found. Succinic acid may occur in small quantities, especially in unripe products. Salicylic, benzoic and formic acids have been reported now and then to occur in traces, the presence of benzoic acid in cranberries and plums being more conspicuous. The acids of some of the fruits like the apricot have not been positively identified. The behavior of citric, malic and tartaric acids in metabolism has recently been discussed in some detail in The Journal.[5] The tentative conclusions reached by the government bureau indicate the following results:

Fruit	Acids found
Apple	Malic only.
Banana	Probably malic only.
Cantaloupe	Malic none—probaby all citric.
Cherry	Malic only.
Cranberry	Citric probably predominates—malic also present.
Currant	Citric probably predominates—malic sometimes present.
Gooseberry	Malic and citric.
Peach	Probably malic only.
Pear	Malic only in some varieties; citric probably predominates in others with small amounts of malic.
Persimmon	Probably malic only.
Plum	Malic only.
Pomegranate	Probably all citric—no malic or tartaric.
Quince	Malic only—no citric.
Raspberry (red) ..	Probably citric only—malic, if present, in traces only.
Watermelon	Malic, no citric.

Bigelow and Dunbar say that these generalizations are not offered as final statements. It is possible that later work may modify them in some particulars. Undoubtedly traces of acids other than those here considered occur in many fruits, and it is possible that these may sometimes be found in important quantities. They add that the results obtained with pears emphasize the danger of drawing general conclusions as to the acid content of fruits from the analysis of a limited number of varieties or even of a limited number of samples. It is believed, however, that the general conclusions drawn from those cases in which a considerable number of samples were examined are correct.

THE TOXICITY OF ULTRAVIOLET LIGHT

Ultraviolet light can give rise to a large number of photochemical reactions. It is not surprising, therefore, to find that it is active also on protoplasmic systems. It has long been known that various small animals such as are found in fresh water flee from places illuminated by ultraviolet light. Under suitable conditions it has a lethal effect on micro-organisms; hence the plan of using ultraviolet radiation for the sterilization of water. To the physician the effect of this form of light waves is familiar through its manifestations on the skin. It is responsible for the inflammation called sunburn (erythema solare). The care taken to protect workmen in electric welding by having them wear spectacles impermeable to light of short wave lengths, and frequently to protect parts of the skin that are exposed, is due to the fact that the arc spectrum of iron is very rich in ultraviolet lines. Ultraviolet light has furthermore already found employment in therapy. It is a remarkable fact that the excitability to ultraviolet rays is independent of temperature—a fact which substantiates the view that they promote their effects by a photochemical reaction, the products of which may excite suitable receptive organs or structures in the skin or elsewhere.[1]

The greater number of the constituents of living cells do not absorb rays of the wave length of visible light. Many of them, however, absorb ultraviolet light so that, as Bayliss remarks, it is not surprising to find that radiations of this kind have a very powerful effect on living cells as a rule. In a study of the possible origin of the toxicity of ultraviolet light, Harris and Hoyt[2] of the University of California point to the general law of photochemical action that only those rays are effective which are absorbed by the system in which the reaction occurs. Visible light rays are not, as a general rule, selectively absorbed by protoplasm, and hence their action is usually confined to specialized pigmented areas which constitute the receptive elements of optical sense organs. Ultraviolet light, on the contrary, is generally highly toxic, even for colorless organisms. Since this toxicity presumably depends on photochemical reactions and is attributable to them, the question presented itself to the California investigators as to the constituent of the protoplasm to which we are to attribute the selective absorption of these rays which is the necessary precedent of their photochemical activity. Various considerations that need not be rehearsed here point to the proteins as the participants in this phenomenon. Kober[3] has confirmed the existence of an absorption band in the ultraviolet in solutions of the amino-acid tyrosin derived from proteins, and also finds that a similar band is exhibited by solutions of phenylalanin. The other amino-acid constituents of the protein molecule exhibit only general (that is nonselective) absorption in the ultraviolet spectrum.

[1] An interesting account of the behavior of ultraviolet light is found in W. M. Bayliss' Principles of General Physiology, London, 1915, p. 569, from which some of the facts given are cited.

The possibility is thus indicated, Harris and Hoyt further remark, that the tyrosin and phenylalanin radicals of the proteins constitute the optical sensitizers which render living cells susceptible to the toxic action of ultraviolet light. If this should prove to be the case, then, they say, passage of the light through solutions of proteins or the aromatic *amino*-acids should, by absorption of the toxic rays, to a greater or less extent deprive the light of its toxicity for protoplasm. An experimental study of the rate at which lower living organisms on exposure to ultraviolet rays are exterminated when living in water, in contrast with a medium containing various organic substances, showed a surprising protective action on the part of some of these. The results obtained by the California investigators are, as they express it, decidedly in harmony with the view that the susceptibility of protoplasm to ultraviolet light is conditioned by the selective absorption of the toxic rays by the aromatic *amino*-acid radicals of the proteins.

Specialization in Military Hospitals.—According to the *Nederlandsch Tijdschrift*, Strauss of Berlin has been appealing to the authorities to distribute the sick and wounded in the hospitals by special groups, as this would materially facilitate the service. All with stomach affections and chronic dysentery, requiring a special diet, should be collected in one hospital. Men with trench nephritis should be separated into two groups, the mild and the severe cases. The idea is already realized to a certain extent in many quarters, but he insists that it should be carried much farther as a great aid to efficiency.

Current Comment

WAR SESSION OF THE CLINICAL CONGRESS

The Clinical Congress of Surgeons of North America, in its eighth annual session at Chicago, was a war session. The clinics of each day, held in the various hospitals, were in large part devoted to demonstrations of war methods, of the new antiseptics, of the new treatment for war burns, and of the handling of cases of shock. But the outstanding features were the afternoon and evening sessions. These brought home to the auditors the imminence of America's active participation in the war. Many of the audience were in uniform—on active duty—and on the speakers' rostrum at each session sat representatives of the medical departments of our Allies, France and Britain, and the Surgeons-General of our own governmental departments. At the opening session, Monday evening, the medical profession responded with repeated outbursts of the greatest enthusiasm to the patriotic utterances of the noted speakers. Even the most doubtful skeptic would have been convinced at that session that the American medical profession is in the war wholeheartedly, and resolved to do its "best" rather than merely its "bit." The greatest outburst of all occurred with the announcement that 18,000 physicians have offered their services, without conscription, to the government, and that special conscription of the medical profession would not be needed. Meetings of this character give to those who attend a perspective as to the stand which the medical profession is taking on problems of the day; at this time, particularly, they give a stimulus to all as to the need of complete and hearty cooperation with the government in the ordeal which it faces; above all, they stimulate in each individual a spirit of self-sacrifice and willingness to "do his bit." This is the greatest service which organizations may render to their members and to the public, and that this is recognized is evident from the statement of Surgeon-General Gorgas that organized medicine has given more aid than any other civilian agency to America's successful activities thus far in the war.

THE CHEMICAL STRUCTURE OF NUCLEIC ACID

The bustle of a busy world, particularly in war time, is likely to leave us oblivious to the beauty or the importance of happenings which do not show on the surface their direct application to everyday affairs. Yet even a brief consideration of the fundamentals of such modern necessities as the dynamo, the wireless, the coal tar dyes or the antiseptics, will carry us back to the little heralded research of some quiet investigator in a modest laboratory. In a spirit of dutiful recognition of important contributions of this sort we cannot refrain from reference to a series of investigations on the chemical structure of the nucleic acids, culminating in recent papers from the laboratory of physiologic chemistry at the Johns Hopkins University.[1] To the biologist the nucleic acids are familiar as integral components of every nucleated cell in living beings; to the physician they further recall the purins, which play a part in the genesis of uric acid. Recent studies have definitely indicated that there are two distinct types of nucleic acids, one of which is found in animal tissues and the other in plants. Our knowledge of plant nucleic acids has been acquired from the study of products from two sources; the wheat embryo and yeast. It has now been ascertained that these plant nucleic acids are probably identical.[2] They are composed of the groups of four mononucleotids (compounds of a nitrogenous substance [either a purin or a pyrimidin], a carbohydrate and phosphoric acid) joined together through their carbohydrate groups. The details of such chemical structure would probably interest most of our readers as little as the intricacies of modern experimentation in the science of immunology on which much useful serum therapy has been based. No one will gainsay, however, that the unraveling of the structure of a compound represented by the empiric formula $C_{38} H_{55} N_{15} O_{29} P_4$ is no mean accomplishment. And to associate this splendid labor largely with the names of American investigators — Osborne, Wheeler, Johnson, Levene, Jacobs, Jones and others — lends a national pride to the accomplishment.

UNWISE ECONOMIES IN DIET

The desire to cooperate with the national Food Administration in its efforts at conservation, and above all the attempt to meet the high cost of living, are leading thoughtful persons throughout the country to scrutinize every phase of the food question. Women, says Miss MacKinnon[3] in "A Lesson in Buying," have fought shy of the phrase "food values," and have preferred to "buy food"; but in these strenuous days the very best service many a woman can render is determined by her ability or inability to manage her food supply. Personal and national necessity is laid on many a woman to make of herself a wise buyer. In many respects—perhaps it should rather be stated, fundamentally—the food problem is one of supplying digestible stores of energy. There is some danger, however, that the calorie may sometimes assume an unwise domination in the selection of human food supplies. It is admitted that conservation should never mean undernourishment or malnutrition; but to avert possibility of these more remote dangers, wise buying of food must sometimes look beyond the energy measure in the selection of the dietary. We are impelled to this remark by reading the advertisement of a cereal food in a current journal addressed essentially to medical readers. The admonition is given to "Eat food that will give you the most energy for the least money." We may accept this advice and likewise admit the statement that "calories measure food energy the same as dollars measure money." But when it is further added that 35 cents' worth of the advertised product will furnish 3,000 calories, a day's need, the implication of the sufficiency of this exclusive product as the sole constituent of the ration must be seriously questioned. It may be true, as the advertisement proudly proclaims, that more calories can be purchased in the form of the vaunted products for 10 cents than is the case in buying sirloin steak, lobsters, bananas or even milk. Such standards of dietary management and menu making are objectionable, however, if they lead to a tendency to "one-sided" regimens. To accept the advice, whether openly stated or implied, to live on a single dietary article, however inexpensive and digestible it may be, is to overlook the fundamental principles that are satisfied by variety in the diet. The fruits and green vegetables may be comparatively expensive when judged solely as sources of food fuel; but they furnish salts and vitamins and "roughage" or "ballast," adding suitable bulk to highly concentrated foods like the cereals, meats, fats and milk products. No cereal or meat offers any considerable supply of lime to the organism; nor are the cereal proteins taken as a whole and by themselves ideal combinations from the standpoint of the present day science of nutrition. The vegetables and fats are appropriate supplements to make a better balanced diet. In his aphorisms applicable to food conditions in war time, Bayliss[4] has said, "Take care of the calories, and the protein will take care of itself." Yet this accomplished physiologist wisely guards against misunderstanding by adding that it is well to insure the presence of accessory factors by taking fresh fruit and salad. Let the novice be cautious in accepting the invitation of the food advertiser when the latter overlooks the advice of the student of nutrition. Without being limited to any single item of food, let us see whether, in the words of Lusk, "we have the intelligence to fitly utilize for the welfare of mankind the resources which God and nature have placed in our hands."

ISOLATION OF TETANUS TOXIN

Heretofore tetanus toxin and other toxins as well as ferments have defied the efforts to isolate them from the mixtures in which they naturally occur. For this reason we know little of the real nature and chemical structure of these remarkable substances; but a way to progress seems to have been found, as London and his co-workers in the Institute for Experimental Medicine in Petrograd[5] now report that under certain conditions tetanus toxin and pancreatic ferments may be carried down on colloidal particles. They find that by the addition of 17 per cent. of ammonium sulphate to culture fluids in which tetanus bacilli have been growing; by centrifugation, the resulting sediment being thrown away; and then by the addition of from 1 to 3 per cent. more of ammonium sulphate, a sediment is obtained which contains the tetanus toxin. This sediment may be dried in vacuum and rinsed repeatedly with ammonium sulphate without thereby reducing the toxicity of the toxin, as minute a quantity as 0.00000002 gm. being fatal for white mice in two days after subcutaneous injection. They also report that by a similar treatment of pancreatic juice with 20 per cent. ammonium sulphate, the amylolytic ferment may be secured in what looks like a practically pure form, while with 30 per cent. the proteolytic ferment, and with 50 per cent. the lipolytic ferments are carried down. These remarkable results indicate that under certain conditions, which vary in each case, tetanus toxin and pancreatic ferments attach themselves to particles and thus become obtainable in nearly pure form. This discovery may mark a long step in advance in the study of toxins and ferments in general, the same principles no doubt being applicable to many other toxins and ferments than those mentioned.

THE CONTROL OF CHILD MORTALITY IN ENGLAND

The causes of high child mortality, particularly in the earliest years of life, are attributed to quite different circumstances by persons approaching the subject from somewhat different standpoints, traditions or experience. The fact is that the circumstances are undoubtedly both numerous and complex, varying with localities as well as with different strata of society. In any attack on a problem of great complexity, it is usually helpful to take into careful consideration the views of those who have had large experience and responsibility in the matter. Hence we are impelled, in connection with a topic that seems trite to some but is nevertheless always before us for earnest debate, to refer to a comparatively recent report of Sir Arthur Newsholme,[1] medical officer to the Local Government Board, London. He offers these comments: Maternal ignorance is sometimes regarded as a chief factor in the causation of excessive child mortality. It is a comfortable doctrine for the well-to-do person to adopt, and it goes far to relieve his conscience in the contemplation of excessive suffering and mortality among the poor. This doctrine has found favor in occasional official reports and in miscellaneous addresses. It embodies an aspect of truth, but it is mischievous when it implies, as it sometimes does, that what is chiefly required is the distribution of leaflets of advice, or the giving of theoretical instruction as to the matters of personal hygiene. Of course, carelessness (the detrimental effects of which the British authority places above ignorance), intemperance, poverty, overcrowding, defective sanitation, industrial employment of married women, the large size of the families of the poor, and other factors enter into consideration in any study of unnecessary child mortality. But in contrasting the wives of the wage-earners with the wives of men belonging to other classes, Newsholme has arrived at the conviction that the difference, apart from the handicap of the former in respect of housing, food supply and sanitation, in the main is one of ability to secure the assistance required in the various contingencies of maternity and early childhood. In England the chief means for rendering this assistance are furnished under the Midwives Act and the Notification of Births Acts. The notification within thirty-six hours enables visits to be made on behalf of the public health authority as early after notification as is thought necessary. The Midwives Act regulates the practice of midwives who attend more than half of the total confinements in England and Wales, these being as a rule the cases in which the additional medical and nursing assistance already referred to are most needed.

THE GASTRIC SECRETION IN INFANCY

It seems to be well established at present that the glands which secrete gastric juice in adults are rarely idle. Even during starvation there is a detectable production of typical gastric secretion — of what Carlson has termed the hunger juice. In adult man the acidity of this fluid tends to be lowered by the regurgitation of alkaline pancreatic and intestinal secretion through the pylorus into the stomach. Taylor[1] has recently discovered that this formerly unsuspected secretion of gastric juice proceeds in the empty stomach of infants also. The acid thus poured out is often as concentrated as that found in the adult stomach during hunger. The secretion contains pepsin; and the more profuse it is, the higher its acidity appears to be. In contrast with what is believed to be the case in the adult, however, Taylor reports that this secretion in the infant is not neutralized in the stomach, but flows out into the small intestine. Regurgitation through the infant's pylorus does not occur. The stomach of a starving infant can apparently secrete from 50 to 200 c.c., or more, of highly acid juice daily. This equals, as Taylor remarks, the amount Engel obtained in his case of pyloric stenosis, which has served as the clinical basis for the theory that hyperacidity or hypersecretion of the gastric juice is an etiologic factor in that disease. In the light of the fact that active gastric juice seems to be available in unexpected quantity and potency, we can understand Taylor's contention that the theoretical objections to tube feeding in premature infants no longer are valid. Deprivation of food is frequently used as a remedial measure in certain digestive disturbances. Taylor suggests that therapeutic starvation in acute alimentary disorders and in summer diarrheas may owe its success in part to the heightened tonus of the alimentary tract, and in part to the pouring out of highly acid detoxicating and disinfecting gastric juice into the small intestine.

PRIMARY TUBERCULOSIS OF THE TONSILS

In recent years the tonsils have been regarded as the portal of entry for many diseases, but it does not appear that examination of tonsils after removal has yielded much information of value in regard to their supposed relationship to disease elsewhere. Mitchell,[2] however, has recently published some interesting observations from Edinburgh on primary tuberculosis of the faucial tonsils obtained from children with tuberculosis of the upper cervical lymph nodes, and from children with enlarged tonsils only and without evidence of tuberculosis of the cervical glands or elsewhere. In the first group were 100 children and six adults. In no case was it possible to establish the presence of tuberculosis prior to removal and examination of the tonsils. The tonsils were rarely painful, and there were no symptoms except swelling of the upper cervical nodes, which in about one fourth of the cases was slight and in the rest rather extensive. On microscopic examination forty-one, or 38 per cent., of the tonsils were definitely tuberculous. Animal inoculation in ninety-two cases gave twenty positive results, the bovine type of bacillus being isolated in sixteen. There were 100 cases, all in children, in the second group with enlarged tonsils only. The cervical glands were palpable in all. Microscopically nine of these tonsils were tuberculous also, all nine giving positive results on inoculation. The type of organism in four was bovine, in two human, and in three undetermined.

[1] Taylor, Rood: Hunger and Appetite Secretion of Gastric Juice in Infants' Stomachs, Am. Jour. Dis. Child., October, 1917, p. 258.

[2] Mitchell, A. P.: Primary Tuberculosis of the Faucial Tonsils in Children, Jour. Path. and Bacteriol., 1917, 21, 248.

The tubercles in the tonsils were situated near the deeper portions of the crypts, and also directly beneath the surface mucosa as well as deep in the tonsil close to the capsule, the first two being the favorite locations. The position of the majority of the tuberculous foci in places within easy access of the oral cavity may be taken as suggesting infection by way of the mouth rather than by way of the blood or lymph by backward transport. The absence of any signs of pulmonary tuberculosis in such cases as these studied by Mitchell may be regarded as evidence that the lesions in the tonsils are primary and not the result of infection from the sputum, and also that the cervical lymph nodes are probably secondarily infected from the tonsils. The latter conclusion would point to the necessity of removal of the tonsils in operation for removal of tuberculous cervical lymph glands. The importance of the milk supply as a source of the infection in cases of tonsillar tuberculosis is emphasized by the fact that in many instances in the series under consideration the infecting organism was of the bovine type. Indeed, the results recorded by Mitchell, which are of special interest because of the large number of cases in which he found tuberculosis, should stimulate to other and even more extensive studies of tonsils, removed for whatever reason, in order that their relation to tuberculous infection and possibly also to other conditions may be determined still more precisely than is the case at the present time.

War and the Activation of Health Interests.—The problems of tuberculosis, venereal disease, insanity and recreation, which, even with all our highly intelligent and energetic propaganda, have hitherto interested only a handful of specialists, comparatively speaking, have suddenly become the common concern of all the branches of the federal and state governments which have anything to do with the fighting forces, and of everybody who has a son or brother or sweetheart, or even a mere acquaintance, in khaki or serge or linen. The prospects are that the American soldier will be the most "protected" and best cared for individual that the world has ever seen, and that there will be protection and care left over for at least a part of the civil population.—The *Survey*.

Medical Mobilization and the War

IN FLANDERS' FIELDS

In reproducing in these columns, October 6, the poem "In Flanders' Fields," by Dr. John McCrae, Montreal, now in France, it was stated that the poem had appeared in the New York *Times*, credited to Capt. John "McRae." In its issue for the same week—October 3—the *Outlook* published the poem under the caption "From His Note-Book," with the following note:

> In a note-book found upon the body of Second Lieutenant A. H. W. Beatty, of the Manchester Regiment, says "Answers," the following verses were found. He had evidently jotted them down shortly before the action in which he met his death. There is something prophetic in them—as though the writer had some foreknowledge that his own time was coming.

The original publication of "In Flanders' Fields" was in *Punch* (London), Dec. 8, 1915, page 468. It appeared anonymously—the common practice of *Punch*—the name of the author being given only in the index of the volume. There it is credited to "McCree, Lt. Col. John"—evidently a typographical error. It is curious that in both *Punch* and the New York *Times* the author's name is spelled incorrectly, and in each differently.

Below is another poem by Lieut.-Col. John McCrae, from the *Spectator* (London), June 30, 1917:

THE ANXIOUS DEAD

O guns, fall silent till the dead men hear
Above their heads the legions pressing on;
(These fought their fight in time of bitter fear
And died not knowing how the day had gone.)

O flashing muzzles, pause, and let them see
The coming dawn that streaks the sky afar:
Then let your mighty chorus witness be
To them, and Caesar, that we still make war.

Tell them, O guns, that we have heard their call,
That we have sworn, and will not turn aside,
That we will onward till we win or fall,
That we will keep the faith for which they died.

Bid them be patient, and some day, anon
They shall feel earth enwrapt in silence deep,
Shall greet, in wonderment, the quiet dawn,
And in content may turn them to their sleep.

—John McCrae.

Physicians Recommended for Commission in the Medical Reserve Corps

During the week ending October 20, 224 physicians were recommended to the Adjutant-General of the Army for commission in the Medical Reserve Corps, the proportion being forty-two captains and 182 lieutenants.

New Red Cross Director-General

Jesse H. Jones, Houston, Texas, has been appointed director-general of military relief of the American Red Cross to succeed John D. Ryan, who was recently appointed to membership on the War Council.

Albany Competes

Dr. Henry L. H. Shaw, Madison Barracks, New York, enters the name of Albany in the competition of cities marked by patriotic physicians. In Albany there are 176 physicians, of whom 148 are members of the County Medical Society; forty-six have received commissions, and forty-one are now in active service; fourteen have been rejected on account of physical disability, age, etc. This gives a percentage of 26 for all physicians, and 31 for members of the County Society, not including those whose applications were rejected.

New Jersey State Society Contributes to Belgian Relief

The Journal is informed by the Belgian Relief Committee of the Emergency Aid of Pennsylvania that the Medical Society of New Jersey, through its treasurer, Dr. Alexander Mercer, Newark, has contributed $1,000 for Belgian relief. This contribution has been forwarded to the Belgian Minister of State, Monsieur de Sadeleer, to be used to aid the Belgian children who are ill and destitute. In order to save the lives of these children it has been necessary to take them out of invaded Belgium for a little while, and a special arrangement has been made through the Dutch legation so that this work is systematically carried on like the "Country Week" plan. The children are taken to Holland, fed, nourished and brought back to health, and then returned to their parents.

Unit of Women for France

The first unit of women doctors and dentists for service in a base hospital in France has been equipped by the Women's Hospital, New York, under the direction of Dr. Rosalie Slaughter Morton, president of the Women's Hospital, and Dr. Elizabeth Johnson Van Slyke, superintendent. The members of the unit are: Drs. Dorothy Child and Florence C. Child, both of Philadelphia; Ethel Lyon Heard, Galveston, Texas; Esther L. Blair, Dixmont, Pa.; Esther E. Parker, Cornell, N. Y.; Marion L. Stevens, New York City; G. F. Nevins and Helen L. H. Woodroffe, San Francisco, and deLam Kinney, New York City, a dentist. Miss Martha Townsend, a graduate nurse of the Women's Hospital, who has served with the Fourth Canadian Contingent at Saloniki and has the rank of lieutenant in the Canadian Army, will accompany the unit, which is now fully equipped and will soon sail for France.

Government Control of War Risk Beneficiaries

In the Congressional Amendment to the Act of Sept. 2, 1914, establishing a Bureau of War Risk Insurance (H. R. 5723), there is ample provision for insuring the families of enlisted men who are war risks in the Army and Navy under present conditions. There is due compensation of widow and children for loss of support by death or disability, and paragraph 3 of section 302 (p. 10), states that the injured shall be provided, where necessary, with governmental medical, surgical and hospital service, and with artificial limbs, trusses and other appliances, "*Provided*, That nothing in this Act shall be construed to affect the necessary military control over any member of the Military or Naval establishments before he shall have been discharged from the Military or Naval service."

In other words it will not be possible to defraud the government through any of these channels, since all beneficiaries of the government through the European war will remain under military control until their relation with the government ceases.

Confers Degrees on Distinguished Foreign Medical Officers

On Convocation Day, October 12, the University of Michigan conferred the degree of Master of Arts on the following representatives of the medical profession among our allies: Capt. John Gilmour of the British Army: contributor to the epidemiology of the plague; decorated by his king for distinguished service in South Africa and in Flanders; Major Edouard Rist of the French Army: member of the Legion of Honor; at one time in charge of the quarantine station at Suez; well known authority on tropical diseases and on tuberculosis; Col. Thomas Herbert Goodwin of the British Army: distinguished scholar and soldier; possessor of the Order for Distinguished Service and commander of the Order of St. Michael and St. George; one of the few survivors of the first British force in France; gentle in word and in manner, resolute in action; Col. Charles Dercle of the French Army: member of the Legion of Honor; recognized student of Arabic, author of a French-Arabic dictionary; received ninety-seven separate wounds from a shell explosion at one time; distinguished scholar and soldier.

French Medical Students and the War

The *Presse médicale* of October 6 reproduces the decision recently voted at a conference of representatives of the medical department of the army and of the medical departments and deans of the various universities and the schools of pharmacy, with the undersecretary of state for the medical department in the chair. It was arranged that for the first year students, who are to be summoned next April, the practical work for the whole year is to be crowded into the winter semester, thus enabling these students to pass before April their examination in this line for the whole year. For those already in army service, this instruction is to be given in the army zone so far as it does not interfere with military exigencies. The examinations are to be held by a university examining board, including also a regular army medical officer. This will enable the candidates to win, according to their status in the examination, military titles corresponding to corporal, sergeant, etc., in the other branches of the army. A new title, *sous-aide-major*, has been recently created for the purpose, and it has been decided that the title of *aide-major* can now be conferred on an advanced undergraduate. The university certificate to be given by the examining board will be the equivalent for the usual final examinations of the two semesters. The authorities are planning to organize practical courses at points where dissecting amphitheaters are available, and the students can be released to study there at intervals, as the airmen go back for courses in aviation. It is realized that if the instruction of the medical students is not allowed to go on within the normal range of time, at the end of the war the medical schools would be swamped with the number of students returning to complete their courses. It has been recognized further that the practical experiences at the front with the sick and wounded have a high educational value. The French authorities for years have accepted the medical course given by the Jesuits in their college at Beyrouth as entitling to practice not only in Syria but in France as well. The only restriction made was that members of medical faculties in France should conduct the examinations, and professors were sent out there for that purpose until the war broke out. The new arrangements just concluded plan a similar system of sending a university examining board to conduct the examinations of the medical students at the front.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA

"War Session"

The eighth annual session of this congress, a "War Session," convened in Chicago, October 22. As is customary, practically all of each day was devoted to special clinics in Chicago hospitals.

The first evening session was held in Orchestra Hall on October 22. John Philip Sousa, conducting the Great Lakes Band, entertained the audience before the arrival of the speakers of the evening. His patriotic marches prepared his auditors for the stirring addresses which followed.

The meeting was called to order by the retiring president, Dr. Fred B. Lund, Boston, who introduced Dr. A. J. Ochsner, chairman of the Committee on Arrangements. Dr. Ochsner welcomed "the distinguished collection of surgeons, especially of military surgeons," stating that they are the most useful members of the medical profession at this critical time. The work of the Committee on the Standardization of Hospitals, which had just closed its meeting, he felt sure would be an inspiration to every man to work toward the standardization of hospitals in his community. The great purpose of the meeting was to become thoroughly familiar with the wonderful work that the Surgeons-General of the Army and Navy and the Public Health Service were doing. "This body of men can help because it is composed of men who are clean in their work, in their mind and in their morals, and they can shorten the war and lessen by hundreds of thousands those who will be lost during the war."

Address of Dr. Lund

Dr. Frederick B. Lund said that there were about 14,000 medical men already enlisted and ready for service and that they needed about 8,000 more, but that medical conscription would not be necessary. He spoke of the wonderful service that had already been rendered by the men in charge of the units that were in France, and of the other men who had volunteered their services and attached themselves to the British Expeditionary Forces two or three years ago. He traced step by step the growth of America's participation in the war. "To the older men among us," he said, "the war has brought the priceless opportunity of doing something unselfish before we die. To the younger man the Army and Navy give abundant opportunity to be of service and to show his skill if he has any." He closed his address with a recitation in the form of a poem, indicting Germany for her crimes against civilization, arousing his audience to a thunderous outburst of patriotic applause.

The President, Dr. John T. Clark

Dr. John T. Clark, Philadelphia, was inducted into office as the new president. "It is a pleasure," he said, "to sit as an auditor in this assemblage of military speakers who are devoting their time and attention to military affairs. They stand in the ranks who deal with salvage rather than destruction." He spoke of the wonderful progress that had been made in the matter of life saving devices that are already in use and of the many others which were promised which would revolutionize medicine and surgery. He was convinced that medicine would come out of this war far richer than when it entered it.

Address of Secretary Daniels

Secretary Daniels of the Navy said that it was to the physicians that the nation turned in time of war with supreme confidence in the belief that by preventive measures they could save the lives of the youths who are willing to rally to the standard, and he wished to express the thanks of America to the men who were making the great sacrifice of devoting their time and their skill to this purpose. He urged that the physicians use their great influence in stamping out the most destroying evil that touches American youth. The hour has struck when the prudery which has made us shut our eyes to this evil is at an end. We cannot win this war unless our soldiers and sailors have steady nerves and clear heads. Men do not have these unless they live straight lives. To put 10,000,000 men under arms and let a portion of them be diseased and make no check on the immoral surroundings that we place them in would be unjust to the nation and unfair to the men. For the first time in the history of the world our country has started on a new line. We have recognized the evil and no longer whisper about it in dark corners. The peril of today is not merely the German guns. In the English army 78,000 men are out of battle because of venereal disease. Congress has passed a law and put it in the hands of our officials to carry forward measures more drastic than were ever dreamed of before. During the last year because of these diseases 141,000 days were lost in the service of the Navy. One person out of every 112 in the Navy had to be treated and almost as many in the Army. We should quit trying to use the poultice when we need the surgeon's knife.

A Message from President Woodrow Wilson

During the evening the following telegram was received from President Woodrow Wilson and read by Dr. C. P. Davis: "To the Clinical Congress of Surgeons of North America: My warmest greetings and best wishes. It cheers us all to see thoughtful, patriotic work done in such good spirit. Woodrow Wilson."

Owing to illness Dr. Franklin Head Martin was unable to be present to introduce the distinguished representatives of the Army and Navy and the visitors from abroad, so Major Edward Martin was requested to take his place.

Address of Surgeon-General Gorgas

Surgeon-General Gorgas said that he had looked forward with dread to the necessary enlargement of his corps on account of the war and had expected to have considerable trouble in the management of so many well informed medical men, but he was happy to say that everything had gone smoothly and there had been no trouble. He thought the fact that he had scrambled along for six months in complete unison with his staff, which contained many eminent men, should have been mentioned in the eulogies that had been showered on him by the other speakers. When he consulted his records he found that not one had been court martialed or had spent a day in the guardhouse. The nation is engaged in the most important war of all history and we must acknowledge that it had responded most nobly in all its branches and not swerved away. No part has been called on to respond so promptly as the medical profession, and he thought it was fair to point out that they had measured up to all that could be expected. He closed by saying that no civilian agency had been of such great service to the government as organized medicine, and he wished to thank the congress of surgeons as all other societies for so full heartedly rendering this aid.

Address of Admiral Braisted

Admiral Braisted, surgeon-general of the Navy, spoke principally of the work of the National Board of Medical Examiners, which had been carrying on its work for two years and reporting from time to time. Its third examination had just been completed. The quality of the examination has been recognized everywhere. It has recently been announced that the Mayo Foundation would receive licentiates without further requirements. Many of the states have arranged to accept the certificate on registration. It had been deemed advisable to go on with the examinations during the period of the war and conduct them even more frequently, going to the larger cities and bringing them before the interns of the hospitals. In the examination just completed there were twenty-nine candidates. The next examination is in January. "It is the privilege of few men to do many great things and the National Board of Medical Examiners," said Dr. Braisted, "is one of the great things of the world."

Address of Surgeon-General Blue

Surg.-Gen. Rupert Blue of the Public Health Service said that this is the time for the estimation of values, and that everything that leads to efficiency brings us nearer victory. He was thankful to announce that the health of the United States was in better condition today than ever before. There had been an awakening of the consciousness of the American people regarding the prevention of disease, and the water and food supplies, the inspection of schools and the control of communicable diseases had all been placed on a good basis. Research has tracked infection to its lair and provided new methods for its control. With the knowledge that we must fight came the realization that these sanitary measures must be followed, and out of this war will come a better, stronger and more enduring national health.

Colonel Goodwin of the British Army

Col. T. H. Goodwin, R. A. M. C., said that Great Britain and America were in this great fight side by side with a common object, identical ideals and with the certain expectation of a mutually attained victory in the future—although probably not in the near future. When he came here five or six months ago Great Britain was in straits owing to the scarcity of medical men necessary, and they owed an unending debt of gratitude to America for the way in which she had responded. Since that time 900 medical officers and nearly 500 nurses have gone across to help on the western front, and their work would be helpful beyond description.

Colonel Dercle of the French Army

Col. C. Dercle of the French Medical Corps received a most hearty welcome. "The manifestations of sympathy moved him more," he said, "because he realized they were meant less for him than for France herself." He spoke of the battle of the Marne where the French army under the command of its chief, Major Joffre, covered itself with glory. "The French," he said, "intimated to Germany to stop—and they have stopped." He could not describe the treasures of devotion he witnessed. The deaths of the men had never been a cause of discouragement on the part of those who followed. On the contrary, there have always been many willing to occupy the vacant places. He highly approved of everything he had seen in the training camps he had visited, and was sure that every physician and surgeon was able to do his war work when strikes the hour. "This was due particularly," he said, "to the personal enthusiasm and activity of Surgeon-General Gorgas, who is giving such wonderful encouragement to every one who works in his service."

Lieut. John Philip Sousa, in a brief speech, said that it seemed to him the meeting was for the purpose of glorifying the medical profession. He then conducted the band in a series of numerously encored selections.

Address of Sir Berkeley Moynihan

"At midnight on Aug. 4, 1914, England—to her lasting honor—declared war against Germany, and at 8 a. m., Aug. 5, 1914, I became for the tenth successive generation a soldier of my sovereign," began Sir Berkeley Moynihan, and he was greeted with a furore of applause. From that time until he stepped aboard the boat at Liverpool he had practiced military surgery, thought of military problems and had lived with military people. There were about 30,000 medical men in England and one-third of them are wearing the king's uniform, and have seen active service or foreign service. In his center in Leeds they had a civilian hospital of 480 beds with a staff of four surgeons and four assistant surgeons. When the territorial system of hospitals was established throughout the country, Leeds was chosen as one of the centers, and they were asked to supply a military hospital of

520 beds. They agreed, and the men attached to the hospital staff became by that act officers in the territorial branch of the army. Of the eight surgeons there are three left at home, himself included—who is often in France, often in London and occasionally in Leeds. With that disabled staff, with the help of the practitioners in the neighborhood, they are running, with an efficiency he would not hesitate to display to the military surgeons of any land, a military hospital of 6,300 beds. The men of the Royal Army Medical Corps are both soldiers and doctors; as soldiers they go into any part of the line from the front trench to the base according to the needs at the moment. Since the war began up to the 25th of August, 1917, they had suffered 1,800 casualties. That number of their men had either been killed or wounded, or gassed or disabled from further service. The highest distinction which any Englishman can gain in the opinion of every Englishman is the Victoria Cross, and they had gained more than their share of that coveted distinction. Two members of the profession have won both the cross and the clasp, indicating that they have won the decoration twice. He paid high tribute to Surgeon-General Gorgas and Major Mayo for their work in connection with the Medical Reserve Corps and in preventive medicine. Ninety-eight per cent. of English soldiers have been voluntarily inoculated against typhoid with the result that they have had only 292 deaths from that disease and only 6,022 cases altogether, whereas in the South African War they had 57,684 cases with over 8,000 deaths, although this infinitely larger army lived under much more difficult circumstances. In many other directions they have helped to stamp out or reduce the prevalence of disease. He begged us never to forget that Germany is a great and formidable nation with an implacable hatred of them and of us, and said we might be sure that in this war with her reserves which come up fresh at the rate of a million and a quarter a year she will use against us every dirty device which she can think of. He believed that America would find as England had found that for her the war would begin when every man of military age in the whole country has offered his services and is prepared to surrender his life to his country.

Address of Major Crile

Major George W. Crile said that during his service in France he had heard no one express the opinion that the enemy was wavering or starving, that he was short of munitions or no longer fights a hard fight, or that the imperial power was crumbling. He had talked with many German prisoners and they were strong and well and well nourished. On the other hand, he had heard from British soldiers that when the Britain and the Teuton meet face to face the Teuton throws up his hands and surrenders, which shows that the Teuton has at least good judgment. He had come to know the British but had known the French less well; he had seen the Briton as a hero and had seen the same on the part of the French, and while he could conceive that the British and French might not win the war he knew that their bodies would never be taken away from the line. They might be buried there but they would never retreat. Everyone in France thinks that the war will be long. The opinion that the enemy is weakening, or is nearing a collapse, and that the war is almost over he had heard only since he arrived in New York. This shows a new danger—how extensive has been the peace offensive waged against the United States.

There are now six American hospitals in France serving with the British Expeditionary Forces. These units have taken over hospitals of from 1,600 to 2,000 beds; there are also several hundred men in the field service, ambulance corps and other capacities. These men know no fear and frequently shake hands with fate, but they stick to their tasks bravely and are men of whom we should all be proud. The British Medical Service has kept their army more free from colds and infection than the civilian population of Chicago. Their medical organization is so perfect that their transport never failed. The death rate from infection and wounds in the French and British lines has been reduced to an incredible minimum, and a vast army of soldiers has been returned to active service, wearing on their sleeves the insignia of having been wounded. The demands of surgery at the present moment are felt by every one; a new set of problems has arisen, and if they are to be solved we must abandon our more personal interests for the time being. Many surgeons must leave their practice and do for the wounded man what had been done for the diseased in every line of surgery. The same intense devotion toward the problems of the wounded soldiers would do for the soldier what had been done for the civilian who remains at home. It is a serious mistake to suppose that military surgery is surgery for the unskilled. It demands a greater versatility and the ability to stand in twelve-hour shifts and to meet every problem that arises in the sequence in which it comes. If a man is interested in any particular thing and says so, the stream is turned on him until he surrenders. More progress has been made in surgery of the chest and abdomen and in the treatment of wounds, of infection and hemorrhage and in the treatment of exhaustion in the past three years of the war than in any time before. This is not a war of men but of ideas, and when thousands are to be saved, what greater gain can be had than to discover means of prevention that may be applied?

Afternoon Session, October 23

At an afternoon session, held at the Congress Hotel, moving pictures of war methods were shown, and special addresses were given. The first address was that of Col. Thomas H. Goodwin of the British Army, in which he described the effect of the war on the English medical profession. Following this address was that given by Major Rist, characterized as the French Osler, on a similar subject, but applying to the French medical profession.

Address of Dr. Frank Billings

An address was then given by Dr. Frank Billings, head of the American Red Cross Commission to Russia, who has just returned from abroad. Dr. Billings brought a message both unencouraging and encouraging in its various aspects. He believes that politically and economically Russia is far from the disorganization pictured by so many writers. With the food now on hand, he is convinced that Russia could easily exist for another year. Numerous supplies of practically every kind are available. In one storehouse in Petrograd there are stored over 6,000,000 suits of underwear for the use of soldiers. However, there is some disorganization, and this shows its effect chiefly in intercommunication; the transportation of food, supplies and munitions is accomplished only with the greatest difficulty. There have been seven cabinets in Russia since the revolution, and these cabinets are created without definite authority, each cabinet having its backing within itself. Dr. Billings was convinced that in her strong young men, particularly Kerensky, who he believes is an honest man and a man who stands for country first, Russia will eventually find herself, and will become a democracy firmly founded possibly through a limited monarchy. The hospitals and the medical department of the army are admirably conducted; in fact, Dr. Billings believes it is equal to that of any in the world. There are certain surgical and medical supplies which Russia requires, but only a few. Before the war, Russia made no synthetic chemicals, but at the time he left, factories in Petrograd were turning out tremendous quantities of needed material. "Russia is making chemicals and drugs as efficiently as we are," said Dr. Billings, "though not to such an extent." He is convinced that after the war not a package of any kind marked "Made in Germany" for consumption in Russia will be received in Russia. Following the address of Dr. Billings, Capt. J. Gilmour of the British Army described the progress of a wounded man from the front to "Blighty."

Report of further meetings will appear next week.

NEWS OF THE TRAINING CAMPS

Fort Benjamin Harrison

ADDITIONS TO OUR WARMTH

At last the long-expected stoves for the barracks have been installed, and with their advent the spirits of the camp have ascended in proportion. Now the evening grind over the Army Regulations and Manual of the Medical Department will be a pleasure, since the tremor (*frigidorum*) will disappear.

Glad tidings of woolen clothing to be sold to the medicos by the quartermaster have reached a more authentic stage than L. O. (Latrine Order) No. 23. It is now understood that an order which provided that no more clothing be furnished by the government to any one until the entire National Army had been completely equipped has been rescinded. Of course, officers are not issued uniforms of any kind by the government, but they have the privilege of purchasing such supplies from the various quartermasters at cost price. The officers of the Medical Reserve Corps in active service are willing to take advantage of the low prices of the quartermaster's department in purchasing supplies, as the difference between these and the constantly ascending prices of the retail merchants is tremendous. It is to be hoped that this purchase privilege will be lasting.

EQUIPMENT OF MEDICAL OFFICERS

More doctors are coming into the training camps constantly, and the variegated sort of equipment that they bring justifies some advice as to the necessities. True, umbrellas no longer appear in their equipment, but they still bring swords and rocking chairs, and, no doubt, if the military equipment establishments sold walking spurs and guard lines, some enthusiastic doctor would be induced to buy. A doctor ordered on active duty should purchase only the absolute necessities. The quarters that will be assigned are limited, and the military authorities will allow only a certain amount in weight and shape for transportation in campaign. It is folly, therefore, to load up with extra baggage, as the excess is destined to immediate shipment home.

The following list will cover all that is necessary for the winter season:

Uniforms.—One heavy weight serge uniform, with cap, for dress. A white linen collar and white cuffs must be worn with this uniform. Many of us find a white linen military stock more convenient than a stiff linen collar.

One olive drab service blouse, with two pairs of trousers, which it is usually possible to purchase at contract price from the government, though the latter privilege is by no means certain. The decorations on the collar of the blouse should be the letters U. S. R. and a caduceus on each side, the letters in front, the caduceus a short distance behind; on each shoulder, the bars indicating the rank, and around each sleeve, the proper distance above the wrist, a circle of brown braid.

No leather belt is worn outside of the blouse. A sword is unnecessary. The belt to support the trousers should be olive drab webbing.

Shirts.—Two olive drab, flannel. More may be obtained from the quartermaster at a very reasonable price. The collar ornaments for the shirt, when the blouse is not worn, are a caduceus on the left side, U. S. R. on the right side, near the front, with the rank designation a short distance behind it. It is better to buy the smaller size of these ornaments.

Puttes.—Leather, one pair, costing about $7. These must be purchased to fit.

Shoes.—One pair of Munson last, tan, a half size longer and one size wider than the shoe ordinarily worn. More shoes may be purchased from the quartermaster's stores on arriving at camp.

Overcoat.—A heavy regulation officer's coat. This also may be purchased from the quartermaster, but alteration will be necessary, and the quartermasters do not always have them in stock. It is better, therefore, to purchase it at home.

A sheepskin-lined, moleskin, short coat, with a fur collar, is very useful, though not necessary. This is called a "trench" coat.

A tan-colored rubber coat is essential, and a pair of light-weight rubber boots useful. These boots should be large enough to allow the wearing of a pair of felt slippers. The latter can also be used in the barracks.

Underwear.—Woolen; two suits.

Socks.—Two pairs, light weight woolen; two pairs, heavy weight woolen.

Gloves.—Woolen, olive drab.

All of these can be procured from the quartermaster on arriving at camp, provided, of course, his stock has not been depleted.

Hat.—A campaign hat, with an officer's hat cord, is necessary. This is to be worn on all occasions, except for dress.

Sweater.—A sweater is not provided for in regulations, but is allowed in camp for fatigue. This must be of the regulation olive drab color. The Red Cross sleeveless sweaters are a great comfort, but must be worn inside the shirts. The Red Cross wristlets are allowed and advisable, if of olive drab.

Pajamas.—Woolen pajamas are a necessity. Nightgowns are ridiculous.

Trunk.—One locker trunk, of regulation size. At present they cannot be procured from the quartermaster.

Cot.—A strong Gold Medal cot, higher than is usually sold —in fact, high enough to allow of placing the trunk underneath.

Bedding-Roll.—This must be purchased, but can be procured in camp for about $11.25.

Blankets.—Bring them with you. Thick, warm, woolen blankets, of dark color, preferably three. Two comforters—one woolen and one cotton, of strong material, the cotton to sleep on, the woolen to wrap up in.

Sheets.—Only the fastidious need sheets, and army life soon cures that disease. The sheet is about as useful at this time of year in barracks as a bedspread would be.

Pillow.—A small, thick, hard pillow, covered with dark material. A pillow slip is unnecessary.

Towels.—Turkish towels answer the purpose best. These can be purchased in camp, at a reasonable price, but it is well to bring several along.

The Red Cross comfort kit and toilet roll will be needed. A safety razor is best, as often one shaves without a mirror and with cold water.

Do not forget the tooth-brush, and to use it. If this has been neglected heretofore, practice its use before coming to camp.

In this connection, it will be well to add that it may serve a good turn to practice daily bathing, as it will be necessary in barracks. Also, it is *à propos* to remark that it would be well to bring your table and home manners with you, as you are expected to be house-broken while living with other men.

A small, light typewriter is a great convenience.

It will be possible to procure everything else needed on arriving at camp, except some ready money to carry you over until you cash your first pay check. I might add that pay vouchers are sent in on the 20th of the month, and not after, and pay therefor is received near the first, by check of large denomination, which it is not always easy to cash.

Instruction in camp is undergoing many changes leading up to actual service conditions, as, for instance, intensive equitation, gas-mask instruction, actual duty in the elaborately constructed trenches on the reservation, etc. Experiences in connection with these duties will be described in the succeeding numbers of The Journal.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

The strength of this command, officers and men at this time is 27,548 of which there are 149 sick in hospital and 286 sick in quarters. There are no cases of alcoholism and but 289 of venereal disease. Nearly all are cases of gonorrhea and only about twelve of these contracted since arriving here. Several cases of mumps and a case of scarlet fever constitute the infectious diseases.

The division is particularly free from serious diseases or surgical conditions, and the sanitary conditions are very good. The command is about immunized to typhoid and variola. Paratyphoid inoculations are nearing completion.

Thirty-First Division, Camp Wheeler, Macon, Ga.

Thirty-three medical officers recently arriving from the training camp at Fort Oglethorpe have almost filled the vacancies in this division. Others to come will complete the commissioned medical personnel in a very short time. The enlisted force is still over 400 short. The camp hospital, which has cared for all patients of the division, was closed on September 18. The medical officers' school was, of necessity, closed during the past week on account of the arrival of drafted men who came in by trainloads—from 1,000 to 4,000 a day. Pneumonia is the only serious disease in the camp. Twelve cases have occurred so far, with no deaths. Major Weil is making a careful study of all cases, in an endeavor to throw some light on the etiology, prevention and treatment of this, now the most fatal of all diseases in our camps. It is feared that the coming cold weather, with a shortage of heavy clothing, may cause an increase in the amount of pneumonia. The Public Health Service is doing good work in Macon and the country about the camp. Under the direction of Surgeon Williams, dairies, lunch rooms, ice cream factories and the like, are being put in good sanitary condition. The American Red Cross and the city of Macon have furnished the funds thus far.

The Commission of Training Camp Activities is beginning a campaign to clean up the city of Macon morally. The chief obstacle is a certain amount of clamor from those financially interested, who claim there is no vice in the city. The venereal wards at the hospital give these claims the lie.

A first aid station has been established in the city in order to care for soldiers who are injured or need medical attention while in the city. This is believed to be the first one of its kind established in the history of the Army.

On account of the breaking up of the Fifty-Sixth Depot Brigade, Major Livingston has been transferred to the One Hundred and Sixth Engineer Regiment.

ONE HUNDRED AND SIXTH SANITARY TRAIN, CAMP WHEELER, GA.

The camp hospital, maintained as a division hospital during the construction of the base hospital, was evacuated on the 16th instant. The transportation of 123 men unable to walk, and fifty-five ambulatory cases, was accomplished by Ambulance Companies Nos. 121 and 123, in two hours and forty minutes.

Major Lorin A. Greene and the Florida Field Hospital officers and men are to be commended for the efficient manner in which the camp hospital was conducted. Working under conditions naturally crude, and handicapped by many shortages, the handling of 888 sick soldiers was conducted.

One hundred and thirty-five men were drawn by the train from the incoming troops from Camp Gordon. It helps some, but we still need 400.

Major George A. O'Connell (Alabama) will command the third motor field hospital just authorized, and Capt. James A. Blackwell (Alabama) the third motor ambulance company.

The conduct of the train as a regiment seems to be working out well. Why the sanitary train is not authorized a train commander of equal grade with commanders of other trains is hard to understand.

Lieut. Edwin S. Byrd (Georgia) has returned to duty a full fledged benedict.

Major George F. Keenan (Massachusetts) represented the medical department of the division at the annual meeting of the Red Cross chapter at Macon, the past week. The needs of the hospital service were discussed, and cooperation urged.

The flooring and walling of the tents for the winter is nearing completion.

Lieut. Daniel Campbell (Florida) has returned from leave of absence as witness in an important murder trial in his home state.

BASE HOSPITAL NOTES

The hospital was opened for the reception of patients at 8 a. m. on Wednesday, October 17, just thirty-nine days from the time the first nail was driven.

The following buildings were then ready for occupancy: commander's and officers' quarters, administration, receiving ward, laboratory, patients and employees' mess hall and kitchen, medical wards 1, 3, 15 and 17, surgical wards 2, 4, 14 and 16, each numbered ward containing thirty-eight beds. As carpenters go out of one end of completed buildings beds for patients come in at the other end. This without interfering with the contracting force. One hundred and fifty stoves for heating have been authorized to be purchased locally and will be in place within a week. The operating pavilion will be heated by using surplus steam from sterilizing plant, and hot and distilled water for the laboratory will be obtained from the same source.

Patients began to arrive at 8:30 a. m., and by 4:30 p. m. 252 had been admitted. The arrival of new cases has kept pace with the utmost endeavor of the personnel but none have been turned away. Today, Saturday, we have ten wards open and 312 patients under treatment. Considering the shortness of the force and the other difficulties under which this work has been accomplished, the result is astonishing, but no more than should be expected of American soldiers. The mess officer deserves special mention for his efforts and results.

This unit has thus early demonstrated what can be done by intelligent, united effort, and every member has shown the proper *esprit de corps.*

Thirty-Fourth Division, Camp Cody, Deming, N. M.

Camp Cody, N. M., the Thirty-Fourth Division, is being formed of troops from the National Guard of Minnesota, the Dakotas, Nebraska and Iowa. Lieut.-Col. J. M. Coffin is division surgeon, and about a hundred medical officers of the division are already working under his direction.

The camp is situated just west of the city of Deming, occupying an area of 4 by 2½ miles, being part of an extensive "bolson" plain near the continental divide, at an elevation of about 4,400 feet, with isolated mountains around it in all directions at distances of from 6 to 50 miles. The Army sanatorium for tuberculosis at Fort Bayard is distant only 54 miles.

The health of the troops is excellent. The climatic and other local conditions are of the best, and the division surgeon has succeeded in preventing the introduction of disease from outside. Surgeons examine all incoming troops promptly on arrival, and isolate all patients with contagious disease. A board of five medical officers is examining all troops for incipient pulmonary tuberculosis. Capt. E. S. Bullock of Silver City, N. M., is president of this board. Similar boards make careful examinations along other lines. Capt. H. R. Carter, Jr., formerly of Johns Hopkins Medical School, is director of the board for cardiovascular examinations; Capt. L. C. Covington of Charleston, W. Va., of the board for ocular diseases and defects, and Lieut. H. Phillips of the Pennsylvania State Hospital for the Insane for mental disease and defects. Less than 0.5 per cent. of the troops have shown incipient pulmonary tuberculosis, 1 per cent. some form of conjunctivitis, and less than 1 per thousand serious mental incapacity.

VENEREAL DISEASE

Venereal diseases have resulted in admissions to the hospital at the rate of 2 per thousand. The municipal authorities in the city of Deming have cooperated loyally and zealously in combating these and other diseases at the source. The segregated district in the city has been abolished, and the reestablishment of houses of prostitution prevented.

Two cases of typhoid have developed among civilians. These infections have been traced in each case to a source outside the camp. No cases have developed among the soldiers, and vaccination against typhoid, paratyphoid and smallpox is being accomplished.

WATER SUPPLY

The water supply comes from wells from 70 to 100 feet deep. Previous examinations have shown the water to be pure, free from alkali and organic pollution, and careful examination of water from each of the four individual wells is now being conducted. An interesting character of the subsoil contributes to the safety of the water supply. The rainfall is very slight, and the water in the ground has come in from the mountains surrounding the plain. These water-bearing strata lie beneath a layer that is almost impervious. Water stands in unlined cisterns for months without apparent diminution, but there is evidence of an exceedingly slow capillary movement of subsoil water upward to replace that lost from the surface by evaporation. This water carries with it lime salts in solution which are slowly deposited a foot or more below the ground surface as the water evaporates, and a considerable layer of "caliche" has thus been formed. This is used for surfacing streets and earthen floors.

Although the soil is thus impervious, the contamination of the surface by excreta and garbage is prevented for other reasons that are obvious. Cesspools in Deming have been replaced by connection with the sewerage system, and where open closets are still used, the dry earth system and fly tight boxes are required. Garbage is sold under contract, and other refuse is burned in the company incinerators over which all waste or dirty water from kitchens or other sources is evaporated.

INSTRUCTION OF MEDICAL OFFICERS

Recently an order was issued from Washington requiring courses of instruction for medical officers with divisions. Such a course of instruction was instituted in Camp Cody, October 1, ten days in advance of the receipt of the order. It is designed to cover the work that will be required of medical officers in campaign, and includes sanitation in camp and on the march, the care of the person, foods, cooking and mess management, as well as the study of Army Regulations, Manual of the Medical Department, organization of the Army, relation of the Medical Department to the rest of the Army, and other administrative work which is essential in an effective organization, and in which the Medical Department necessarily plays a very large part. The course is objective and practical, and includes participation in regimental, brigade and divisional maneuvers.

In the more specifically medical part of the course, regular conferences are held in the wards of the base hospital, at which regimental surgeons and others discuss with the hospital staff cases which they have sent in, paying especial attention to those in which the diagnosis at the base hospital differs from that on admission.

Lectures by specialists present with the division, or sent for the purpose, deal with various departments of military medicine and surgery, diseases incident to life in the trenches, gas poisoning, and the special conditions that the Medical Department is likely to have to meet during the present war.

The physicians who have exchanged civilian life for the orderly round of military duties in the camp are finding the work heavy but full of professional and human interest. All are finding the well ordered life in the mountain air good for health and spirits, and are happy in the consciousness of giving increasingly efficient service to the United States.

Thirty-Ninth Division, Camp Beauregard, Alexandria, La.

Camp Beauregard, a National Guard camp, houses the Thirty-Ninth Infantry Division, composed of the National Guard units of Arkansas, Louisiana and Mississippi, and is under the command of Major-Gen. Harry B. Hodges. Only about 7,000 troops have arrived to date; but they are coming in rapidly, and a full division of 27,000 men will be here soon. The first medical officer to arrive was Major George F. Lull, commanding officer of the base hospital, who reported for duty, August 13. Lieut.-Col. William G. Schauffler, late surgeon-general of the New Jersey National Guard, who is division sanitary inspector, was the next arrival. Under his careful and efficient supervision the entire camp has been put in a most satisfactory sanitary condition. Next came Lieut.-Col. William Smart of the Medical Corps, who is division surgeon. Colonel Smart is a son of the late Surgeon-General Smart of the Army. At present time there are forty-five medical officers in camp. There are ten regimental infirmaries, one field hospital and the base hospital. The latter is located on a hill in the pine woods about 2 miles from the rest of the camp. The buildings are not yet quite complete, so the patients of the camp who are too sick to be treated in the regimental infirmaries or the field hospital are being taking care of in the Alexandria Sanatorium by members of the staff of the base hospital. However, the constructing quartermaster has given assurance that the base hospital will be sufficiently complete to receive patients during the present week. The personnel of the base hospital staff includes the commanding officer, Major George F. Lull, M. C., who brings to the position a wide experience acquired in Panama and on the Border, and the chiefs of the sections, as follows: medicine, Major J. B. Guthrie, professor of clinical medicine in Tulane University; surgery, Major John T. Burrus, High Point, N. C.; orthopedics, Capt. E. D. Fenner, professor of orthopedics in Tulane University; surgery of the head, Capt. W. C. Heisey, McKeesport, Pa.; neurology, Capt. John T. Sample, Saginaw, Mich., formerly medical house officer of Johns Hopkins Hospital; section of venereal diseases, Dr. Loyd Thompson, Hot Springs, Ark., editor of the *American Journal of Syphilis;* and laboratory, Dr. Charles Burhans, Cleveland.

MEASLES

An epidemic of measles broke out in the First Louisiana Infantry the latter part of August, and to date there have been about 100 cases. There are now twenty-seven cases, most of them comparatively mild. As these cases constitute the majority of the cases of illness in the camp, the clinical work of the staff of the base hospital has been comparatively light. The time is taken up with drills, classes on the ever present paper work, the bugbear of the medical reserve officer, French lessons and quizzes. The *esprit de corps* is excellent, and when the division goes to France, the base hospital should prove a most efficient unit.

TUBERCULOSIS SURVEY

A special detail of medical reserve officers and contract surgeons, headed by Major W. G. Owen, has been sent to the camp to make a survey of the entire command for tuberculosis. About 300 men are being examined daily, and so far three positive cases have been discovered. All men that show suspicious signs are placed in bed under observation for ten days with daily sputum examinations.

Seventy-Sixth Division, Camp Devens, Ayer, Mass.

Fire in the Army base hospital at Camp Devens, Ayer, Mass., believed of incendiary origin, periled the lives of 300 patients, but by prompt action, all patients were removed without casualty. The fire was extinguished before the main building was reached. The process of reconstruction is expected to go forward rapidly and the patients will be handled temporarily in other buildings.

Eighty-First Division, Camp Jackson, Columbia, S. C.

The cantonment at Camp Jackson is on a plateau northeast of Columbia. It occupies about 3,000 acres of land which only three months ago was largely under cultivation. Even now large fields of cotton can be seen about it. From the entrance of the camp to the base hospital a distance of over 2 miles must be traversed. The base hospital comprises eighty buildings, and the work is being rushed to completion. The hospital quarters for officers will be ready by the end of the week.

The camp is situated on a ridge, on the continuation of which Camden, the southern winter resort, is built. From this site the distant hills can be seen reaching the sky.

The field hospital contains no sick whose diseases are due to camp life.

The barracks have electric light and heat, latrines which are heated by stoves, and shower baths with hot and cold water. The drainage and sanitary arrangements are complete; these have been under the direction of Major Thomas J. Leary.

The base hospital is built on the highest level of the cantonment: "as the mountains are round about Jerusalem," so are the hills about Camp Jackson. The buildings can accommodate 1,500 patients, and are connected by covered porches; all are grouped about a center, access to which can be gained, thus providing safety against fire. Lieut.-Col. Kent Nelson is the division surgeon, and Major James F. Johnston, assistant and now sanitary officer. The commanding officer of the base hospital is Major Thomas J. Leary, a Regular Army man with experience in Panama, and in the Philippines under General Pershing. The chiefs of the staff of the base hospital are Major W. W. Herrick, internist; Major Richard H. Hutchings, psychiatrist; Major James Stone, surgeon; Capt. Henry Tucker, in charge of venereal diseases; Capt. John W. MacConnell, otolaryngologist; Capt. Frederick W. Baeslock, chief of the pathologic laboratory; Capt. Harrison A. Greaves, roentgenologist, and Capt. Burton Chance, ophthalmologist.

Major James F. Johnston was transferred, October 16, to the post of division sanitary inspector so ably conducted by Major Leary, who was appointed commander of the base hospital. The staff was organized as a central board, under Colonel Nelson, to decide on the acceptability of the rejected men found physically or mentally deficient by the regimental surgeons, who hold examinations of the drafted men daily. Assisting in this examination are Lieutenants Hart, Braun, Long, Gerhardt, Gibbs, Robbins, Woodhouse, Heard, Lattin and Pendleton. So far over 1,400 men have been rejected.

The city has opened its heart to the officers and men with true Southern hospitality, and already they are welcome to enter many a charming home. Entertainments have been prepared for all. The churches keep open their buildings Saturday nights, and a number of eat-shops have been established for the comfort of the soldiers visiting the town. Car lines have been extended to the camp, and it is hoped that express steam trains will run later. Every one is happy, and I have yet to see a man or officer with a "grouch." There are all kinds of sports, including baseball and football, but no "highballs," for South Carolina is "bone dry" to the advantage of the entire cantonment.

PERSONAL

Capt. Wayne Babcock, regimental surgeon, has been transferred to the base hospital at Fort McPherson.

Lieut. Stuart Hart, who had conducted the cardiovascular studies, was recalled to New York.

Capt. Burton Chance received his commission in September.

Lieutenant Birnie recently arrived from Fort Sill. He came to conduct the gas defense drills. A gas house is being constructed in which the gases will be demonstrated.

Saturday, October 6, many members of the base hospital were guests at a barbecue held at White Pond, an attractive sheet of water about 20 miles from Columbia. To most this was a unique feast. Besides the delicious food, the occasion gave the medical officers an opporunity to meet socially Generals Barth and McIver and many officers of the line.

Shortly after his arrival at the cantonment, Captain Tucker instituted an investigation of prostitution in Columbia in which he was ably assisted by several public spirited citizens who had become concerned over the ravages of the social evils. The name of every prostitute and many suspects and the location of all houses in which the trade is carried on is known. The Army of the United States, with cooperation of the civil authorities, can eradicate social diseases. Columbia is "bone dry," and if any argument for prohibition is needed, behold the National Army!

Eighty-Fifth Division, Camp Custer, Battle Creek, Mich.

Major John Ridlon has been in camp since October 16, and has given especially interesting and practical talks to the medical officers of this camp on conditions of orthopedic surgery. There was a large attendance at these meetings, as orders from the division surgeon requested every medical officer to attend. After hearing these lectures no one regretted having complied with the order, as the major presented the subject in such a way as to be of much benefit. He also delivered a course of practical talks on the care of the feet to a large number of line officers.

The medical society of Battle Creek (Calhoun County Medical Society) has passed resolutions making two regular monthly meetings instead of one. This was done for the purpose of bringing the medical corps of the division in closer touch with the profession of Battle Creek and things of medical interest other than from a military point of view. At the last meeting, October 2, Dr. Hugh T. Patrick of Chicago talked on "Diagnosis of the Functional from the Organic Diseases of the Nervous System." Major Lewis Wine Bremerman, Camp Custer, Mich., talked on "Diagnostic Points in Genito-Urinary." The meeting was well attended, both by regular members and by the medical corps of the Eighty-Fifth Division.

VENEREAL DISEASE

The subject of venereal diseases is paramount at this time. Calhoun County Medical Society passed special resolutions at the October 2 meeting, having in mind the protection of the soldier against these diseases.

Camp regulations are such that they require the isolation of all venereal diseases among soldiers, no passes being permitted to these men until they are free from infection and thus prevented from spreading the disease. Whenever it is possible to obtain from the soldiers who are infected the name of the women from whom they contracted the disease, it is forwarded to the health officer in Battle Creek. If this plan works out, there is no reason why venereal diseases in this particular division should not be reduced to a minimum, for there is no question that if the resolutions are carried out to the letter, the infected professional prostitute will find difficulty in transmitting her infection to others.

Eighty-Sixth Division, Camp Grant, Rockford, Ill.

The medical condition of Camp Grant continues to be satisfactory. Many of the cases in the base hospital are those found by the regimental surgeons in making their routine examinations of all the recruits, and are waiting for their discharge papers to come through. In justice to the local boards, it should be said that most of these cases are of such a nature that they could not be recognized at a single examination, but were brought to light by more extended careful observation.

In examining large numbers of recruits, it is necessary to use every device possible to save time that does not diminish the efficiency of the examination. It has been found most practical to have the examination of each man divided among several medical officers than to have each recruit completely examined by a single officer. The following method will run through about eighty an hour: Thirty recruits are admitted into the room at a time and are stripped. One physician weighs and measures the recruit, and notes the muscular development; another listens to the heart and lungs; the next examines the genitalia and for hernia, hemorrhoids and varicose veins; the fourth tests the muscles and joints; the fifth counts the absent teeth and looks at the nose and throat, and two men examine the eyes and ears. In addition it is often advantageous to vaccinate the recruits for smallpox and typhoid fever. In this case one man is assigned to each form of vaccination. With this division of labor, the line of recruits will pass through smoothly. All questionable recruits fall out of line and are passed on by the commanding officer and, if necessary, are told to report at a less busy time for a more extended examination.

Each medical officer has an enlisted man who records his findings on the proper form and passes it on to the next. In this way, when the recruit has finished his examination, there is a complete record of the findings ready for the signature of the commanding officer. The finger prints are taken by a noncommissioned officer.

The vaccinating officers usually have two helpers. For smallpox, the first washes the arm with soap and water, the second applies ether or alcohol. For typhoid, the first paints the arm with the tincture of iodin, and the second runs the sterilizer.

There have been few changes in the personnel in the last two weeks. The various departments are perfecting their organization and are running smoothly. The laboratory has started a menagerie which at present consists of several white mice. The personnel are rapidly becoming sophisticated, and have stopped looking for 5 yards of skirmish line.

Eighty-Seventh Division, Camp Pike, Little Rock, Ark.

The arrival of forty-five medical officers from Fort Oglethorpe, October 19, marked the practical completion of the commissioned medical personnel of the Eighty-Seventh Division. These were assigned to the three field hospitals yet without officers and to four ambulance companies not having their full commissioned quotas. The remaining officers were divided among the various regimental infirmaries and the infirmaries of the depot brigade.

With the completion of the commissioned personnel, it is expected that the work of training will go rapidly forward, the enlisted personnel being drawn as rapidly as possible from the drafted army. A full and complete course of instruction will be carried out, being very similar in character to that given at the various medical training camps. While a large percentage of the medical officers in this division were former students at training camps, there is a certain percentage who were there only a short time, and a few who have had no special instruction along army medical lines. The plan as outlined provides for the training and instruction of the untrained by those who have had the advantage of the full course of instruction in training camps. This plan will not only give plenty of "work for idle hands to do," but also will add greatly to the interest of the "army medical game," and relieve to some extent the monotony that is sure to creep into camp life.

The work of examining the colored troops continues, and as the War Department is very anxious to expedite this work, the examining medical officers are not allowed to sleep on post. As soon as examined and given the triple typhoid vaccination and equipped, the colored troops are removed to other cantonments. An officer who traveled on one of the troop trains with these men makes the statement that wherever the troops were "paraded" for the purpose of exercise the populace unvariably commented on their soldierly appearance and the aptitude with which they acquired the drills.

The general health of the command remains good, measles being the prevailing ailment, and there being only about thirty or forty cases of that in a command of over 20,000. The number of cases of malaria is very small.

Weather conditions are better of late. The heat has been great during part of the day, and the nights are cold. The dust has also been a great hindrance to effective work whenever the wind blew. A good rain has laid the dust and steadied the atmosphere to a more nearly equable temperature during the past twenty-four hours.

Capt. G. H. Campbell, alienist at the base hospital, has become a major. Otherwise everything is "quiet along the Potomac" as regards promotions.

Eighty-Eighth Division, Camp Dodge, Des Moines, Iowa

The medical department at Camp Dodge is now a well organized institution. We have the distinction of being the first troops to arrive at the new National Army cantonment, and have played a considerable part in the work of the camp thus far.

August 25, thirty-three medical officers and 200 of the enlisted personnel of the Medical Department were sent from Fort Riley, Kan., to Camp Dodge. For most of us it was our first experience traveling with troops. When we arrived at Camp Dodge, very few of the barracks were completed, and none of the sewerage, water or lighting accommodations were installed. However, Major Fronk of the sanitary department had arrived before us and had made adequate measures for our care, although they were of a rather rough nature.

During the first two weeks spent here, Lieut.-Col. Shook, the division surgeon, organized the various regimental detachments and had them ready for the physical examination of the first men of the draft on their arrival, September 10. The rapidity and thoroughness with which these men were examined spoke well for this organized work. Since then the second increment of the draft army has arrived and all have been examined, and the regimental surgeons are now having a little respite while awaiting the third increment of men, which will arrive about October 25.

About one week ago, forty-eight medical officers arrived from Fort Riley after the completion of their course of instruction at that place. These officers have been assigned to the several regiments, field hospital companies and ambulance companies, filling these several organizations, so that each now has their required number of officers.

BASE HOSPITAL

The base hospital was organized under the directorship of Major Craft, a Regular Army officer. As the new base hospital buildings were not completed, it was installed temporarily in four barracks provided for the use of the ambulance companies later on.

The new buildings for the base hospital are about 80 per cent. complete. November 1 is the date fixed now for the completion of this hospital. Meanwhile the base hospital is doing a rushing business in the temporary barracks in which they are now located.

"Colds," influenza and pneumonia are the predominating illnesses. Every venereal patient is confined to the hospital until the discharge ceases or the contagious stage is past. There have been three cases of delirium tremens due to the sudden cutting off of the liquor. Without doubt, the total abstinence of the soldiers from liquor will be the greatest step in disease prevention which the War Department has taken, and the draft men who have been excessive users, while suffering most at first, will be greatly benefited by their army life.

A number of surgical operations have already been performed successfully in the improvised operating room. This includes two cases of acute appendicitis.

The examination of the recruits has revealed 100 cases of diseased teeth and tonsils. The dental and nose and throat services of the base hospital are busy removing these foci of infection. This is a form of preventive medicine and surgery that has been neglected in other wars. While the sanitary department is busy removing the causes for disease in the physical surroundings of the men, our medical and surgical staffs are busy removing the causes for disease in the men *themselves. It is impossible to estimate the value of these* measures to the efficiency of our new Army.

There have been two deaths thus far, one acute mania and one from delirium tremens.

AMBULANCE COMPANIES

Four weeks ago the Red Cross ambulance company of Denver, under the command of Captain Hopkins, arrived. This company is composed chiefly of college men from the University of Denver and the University of Colorado.

Another Red Cross ambulance company arrived three weeks ago from Flint, Mich. It is composed of men from the automobile industries of Michigan, and was equipped by these concerns. Captain Winchester is in command.

NEWS NOTES

Major Black, M. R. C., Milwaukee, Wis., spent three days at the base hospital last week in his general inspection. He reported that the hospital and the type of work being done was excellent.

Major H. E. Mock has been relieved from duty at Camp Dodge, and has been called to the Surgeon-General's Office, Washington, D. C.

A tuberculosis board, headed by Captain Peck, arrived at Camp Dodge a few days ago, and began work immediately.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Oct. 12, 1917

1. TOTAL STRENGTH OF TROOPS	1,000,680
Admission rate per 1,000 ....weekly	19.1
Non-effective rate ....weekly	19.1
2. NATIONAL GUARD—STRENGTH	303,967
Admission rate all camps ....weekly	20.5
Non-effective rate all camps ....weekly	21.8
Camps showing admission rate higher than average:	
29th Division, Camp McClellan, Anniston, Ala.	21.3
31st Division, Camp Wheeler, Macon, Ga.	28.6
33d Division, Camp Logan, Houston, Tex.	24.1
34th Division, Camp Cody, Deming, New Mex.	21.9
35th Division, Camp Doniphan, Fort Sill, Okla.	26.4
36th Division, Camp Bowie, Fort Worth, Tex.	28.7
38th Division, Camp Shelby, Hattiesburg, Miss.	30.9
39th Division, Camp Beauregard, Alexandria, La.	28.6
40th Division, Camp Kearney, Linda Vista, Calif.	34.5
42d Division, Camp A. L. Mills, Garden City, L. I.	23.4
Camps showing non-effective rate higher than average:	
30th Division, Camp Sevier, Greenville, S. C.	24.5
31st Division, Camp Wheeler, Macon, Ga.	29.2
32d Division, Camp MacArthur, Waco, Tex.	32.4
33d Division, Camp Logan, Houston, Tex.	26.1
36th Division, Camp Bowie, Fort Worth, Tex.	29.8
38th Division, Camp Shelby, Hattiesburg, Miss.	36
39th Division, Camp Beauregard, Alexandria, La.	23.7
42d Division, Camp A. L. Mills, Garden City, L. I.	24.9
3. NATIONAL ARMY—STRENGTH	428,855
Admision rate all camps ....weekly	19.1
Non-effective rate all camps ....weekly	14.6
Camps showing admission rate higher than average:	
79th Division, Camp Meade, Annapolis Junction, Md.	19.7
82d Division, Camp Gordon, Atlanta, Ga.	22.2
85th Division, Camp Custer, Battle Creek, Mich.	20.2
87th Division, Camp Pike, Little Rock, Ark.	23.7
88th Division, Camp Dodge, Des Moines, Iowa	22.1
89th Division, Camp Funston, Fort Riley, Kan.	29.7
90th Division, Camp Travis, Fort Sam Houston, Tex.	31.6
91st Division, Camp Lewis, American Lake, Wash.	30.4
Camps showing non-effective rate higher than average:	
78th Division, Camp Dix, Wrightstown, N. J.	14.7
80th Division, Camp Lee, Petersburg, Va.	25
85th Division, Camp Custer, Battle Creek, Mich.	16.5
88th Division, Camp Dodge, Des Moines, Iowa	28.5
91st Division, Camp Lewis, American Lake, Wash.	28.3
4. VENEREAL DISEASE—	
Admission rate all troops	133.4
Admission rate National Guard (Camps) ....annual	106.2
Admission rate National Army	204.8
Camps National Guard having rate above average:	
29th Division, Camp McClellan, Anniston, Ala.	139.3
30th Division, Camp Sevier, Greenville, S. C.	150.6
31st Division, Camp Wheeler, Macon, Ga.	254.5
33d Division, Camp Logan, Houston, Tex.	134.5
34th Division, Camp Cody, Deming, N. Mex.	134.2
35th Division, Camp Doniphan, Fort Sill, Okla.	114.9
36th Division, Camp Bowie, Fort Worth, Tex.	168.6
37th Division, Camp Sheridan, Montgomery, Ala.	107.1
38th Division, Camp Shelby, Hattiesburg, Miss.	235.7
39th Division, Camp Beauregard, Alexandria, La.	221.1
Camps National Army having rate above average:	
87th Division, Camp Pike, Little Rock, Ark.	1,103.3
89th Division, Camp Funston, Fort Riley, Kan.	479.4
90th Division, Camp Travis, Fort Sam Houston, Tex.	384.7
91st Division, Camp Lewis, American Lake, Wash.	229.8
5. NUMBER OF CASES OF PNEUMONIA	93
Highest number in any one camp ....(Dodge)	10
NUMBER OF CASES OF MENINGITIS	16
Highest number in any one camp ....(Shelby)	4

Ohio

To Camp Custer, Battle Creek, Mich., for duty, from Fort Benjamin Harrison, Lieuts. RALPH E. POWERS, Akron; EMIL E. WOLF, Cleveland; THEODORE J. KASINSKI, Youngstown.

To Camp Sherman, Chillicothe, O., for duty, from Fort Benjamin Harrison, Lieuts. JOHN T. GIBBONS, Celina; JOHN R. CRUM, Forest; JAMES D. VARNEY, Greenfield; for temporary duty, ALDO V. SIBERT, Lima; ROBERT M. FULWIDER, Zanesfield.

To Camp Taylor. Louisville, Ky., for temporary duty, from Medical Officers' Training Camp, Fort Benjamin Harrison, Lieut. ELMER A. KLEIN, Norwood.

To Fort Oglethorpe for instruction, Lieut. GEORGE C. SMITH, Mansfield.

To Philadelphia, for a course of instruction in orthopedic surgery, Lieut. ALLEN N. WISELEY, Ada.

Oklahoma

To Camp Doniphan, Fort Sill, Okla., for temporary duty, Lieuts. CHARLES W. BACON, Enid; R. EARLE SMITH, Gracemont.

To Philadelphia, for a course of instruction in orthopedic surgery, from Army Medical School, Lieut. DAVY L. GARRETT, Altus.

To the inactive list of the Medical Reserve Corps of the Army, Lieut. FRANK L. CARSON, Shawnee.

Oregon

To Fort Douglas, Utah, for duty, Lieut. JAMES A. BEST, Pendleton.

To Neurological School, University of Pennsylvania, Philadelphia, for intensive training in brain surgery, Capt. LAWRENCE SELLING, THOMAS M. JOYCE, Portland.

To the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, Lieut. HAROLD T. ALLISON, Heppner.

Pennsylvania

To Camp Beauregard, Alexandria, La., for duty in the surgical service, from Fort Oglethorpe, Lieuts. LEOPOLD M. JACOBS, Philadelphia; NORMAN A. TIMMONS, South Bethlehem.

To Camp Custer, Battle Creek, Mich., for duty with the division of ophthalmology, section of surgery of the head, Lieuts. MARION H. POWERS, Point Marion; for duty from Fort Benjamin Harrison, JOHN H. MURRAY, Punxsutawney.

To Camp Dix, Wrightstown, N. J., for temporary duty, Lieut. SNOWDEN K. HALL, Pittsburgh.

To Camp Hancock, Augusta, Pa., Lieuts. HAROLD S. BROOMALL, for duty in the division of otolaryngology, section of surgery of the head; from Fort Oglethorpe, EDWARD W. COLLINS, Philadelphia; for temporary duty from Fort Oglethorpe, THOMAS A. BOOTH, Boothwyn; EDMOND B. PIPER, Philadelphia.

To Camp McClellan, Anniston, Ala., for duty in connection with the division of otolaryngology, section of surgery of the head, Lieut. AARON L. BISHOP, Philadelphia.

To Camp Meade, Annapolis Junction, Md., for temporary duty, Lieuts. JAMES S. HAMMERS, Danville; EDWIN S. COOKE, Philadelphia; GEORGE G. GRAZIER, for duty in charge of the division of otolaryngology, section of surgery of the head, WILLIAM P. BARNDOLLAR, Pittsburgh.

To Camp Sherman, Chillicothe, *Ohio,* for duty, from Fort Benjamin Harrison, Capt. FREDERICK A. RUPP, Lewistown.

To Camp Wadsworth, Spartanburg, S. C., for duty in charge of the division of ophthalmology, section of surgery of the head, from Camp McClellan, Anniston, Ala., Lieut. CHARLES M. STILES, Philadelphia.

To Camp Wheeler, Macon, Ga., *for* duty *from* Fort Oglethorpe, Lieuts. FRANKLIN P. LYTLE, Birdsboro; JOHN H. STEARNS, Delaware Water Gap; CHARLES C. CROUSHORE, Greensburg; EDWARD Y. ORD, McKeesport; PORTER M. WALL, Monongahela; VINCENT J. FENERTY, JACOB J. RUTBERG, Philadelphia; WILLIAM J. STEWART, Pittsburgh; WALTER M. BERTALET, THOMAS M. SNYDER, Reading.

To Canal Zone, Panama Canal Dept., for duty, Capt. ISAAC H. JONES, Philadelphia.

To Fort Benjamin Harrison for duty in the bacteriologic laboratory of the base hospital, from Army Medical School, Lieut. CARL GOEHRING Pittsburgh.

To Fort Oglethorpe for instruction, Lieuts. HOWARD P. BLAKE, Altoona; CLIFFORD B. LULL, Philadelphia.

To Fort Riley for duty in the surgical service, from Fort Oglethorpe, Lieuts. GEORGE M. PURVES, ARTHUR R. WOODS, for duty in connection with the division of ophthalmology, section of surgery of the head, from Fort Benjamin Harrison, for duty in the bacteriologic laboratory, Philadelphia.

To Gettysburg, Pa., for duty with the machine gun battalion, from Fort Oglethorpe, Lieut. WILLIAM E. LEFFLER, Ashland.

To Harvard Medical School, Boston, Mass., for orthopedic instruction, Lieut. RANDALL ZIMMERMAN, Wilmerding.

To Neurological School, University of Pennsylvania, Philadelphia, for intensive training in brain surgery, Lieut. LOUIS H. MAYER, JR., Johnstown.

To Pine Camp, New York, for duty with the 15th Field Artillery, from Fort Oglethorpe, Lieut. ELMER HESS, Erie.

To Pittsburgh, Pa., for a course of instruction in military *roentgenology*, Lieut. CHARLES H. POOLE, Ruffsdale.

To San Antonio, Texas, Kelly Field, for duty, Lieuts. RAY N. LEWIS, *Apollo;* HENRI SCHMID, *Pittsburgh.*

To Walter Reed General Hospital, Takoma Park, D. C., for instruction in tuberculosis examinations, from Plattsburg Barracks, N. Y., Capt. ALBERT P. FRANCINE, Philadelphia.

To Washington University, St. Louis, Mo., for three weeks' intensive training and on completion of this course to return to his home and to the inactive list of the Medical Reserve Corps, Capt. THOMAS C. STELLWAGON, JR., Philadelphia.

To inactive list of the Medical Reserve Corps, from Fort Ethan Allen, Vt., Major JACK G. GITTINGS, Philadelphia.

Philippine Islands

To Manila, P. I., Philippine Dept. for duty, Major HENRY PICK, Manila.

Rhode Island

To Camp Custer, Battle Creek, Mich., for duty, from Fort Benjamin Harrison, Lieut. PATRICK J. MANNING, Wickford.

To Camp Sherman, Chillicothe, Ohio, for duty, from Fort *Benjamin Harrison,* Lieuts. WILLIAM P. BERNARD, Central Falls; FRANCIS E. CROGHAN, Providence.

South Carolina

To Camp Lee, Petersburg, Va., for temporary duty, Lieut. WILLIAM E. LESTER, Lake View.

To New York, for orthopedic instruction, from Army Medical School, Lieut. KARL L. ABLE, Leesville.

To San Antonio, Texas, Kelly Field, for duty, Lieut. WILLIAM S. McMURRAY, Lockhart.

Honorably discharged from the Medical Reserve Corps of the Army, Major FRANCIS L. PARKER, Charleston.

South Dakota

To Fort Riley, for duty in the surgical service, Lieut. LINDSAY Z FLETCHER, Montrose.

Tennessee

To Camp Hancock, Augusta, Ga., for temporary duty, from Fort Oglethorpe, Lieut. DAVID T. AUSTIN, Bogota.

To Camp McClellan, Anniston, Ala., for temporary duty, Lieut. THOMAS M. HARPER, Medina.

To Camp Pike, Little Rock, Ark., for temporary duty, Capt. WILLIAM E. HOWELL, Morristown.

To Camp Wheeler, Macon, Ga., for duty, from Fort Oglethorpe, Lieut. ROBERT B. GRIFFIN, Ridgley.

To Cornell Medical College, New York, *for a course of instruction in* military roentgenology, from Medical Officers' Training Camp, Fort Benjamin Harrison, Lieut. THOMAS O. MENEES, Nashville.

To Fort Oglethorpe for instruction, Lieut. WILLIAM C. COLBERT, Memphis.

To Neurological School, University of Pennsylvania, Philadelphia, for intensive training in brain surgery, Capt. WILLIAM H. SMITH, Brunswick.

To San Antonio, Texas, Kelly Field, for duty, Lieut. CHARLES HENDLEY, Cottagegrove.

Honorably discharged from the Medical Reserve Corps of the Army on account of being physically disqualified for active service, from Fort Oglethorpe, Lieut. SNETHEN B. DUGGAN, Engleville.

Texas

To Atlanta, Ga., for duty in hospital laboratory, Lieut. GEORGE C. BRUNNELL, *El Paso.*

To Camp Dodge, Des Moines, Iowa, for temporary duty, Lieut. JOHN E. WILSON, Shiro.

To Camp Grant, Rockford, Ill., for duty as chief of the surgical service, from Medical Officers' Training Camp, Fort Oglethorpe, Capt. JOHN W. LANE, Houston Heights.

To Camp McClellan, Anniston, Ala., for duty, from Manila, Philippine Islands, Lieut. RUFUS H. HAGOOD, JR., Texas City.

To New York, for orthopedic work, Lieut. QUINCY B. LEE, Wichita Falls.

To *report by telegraph to the commanding* general, Southern Dept., *for assignment to duty, Lieuts.* DIMETRUS J. LOUIS, *El Paso;* THOMAS D. VAUGHAN, Taylor; LYTTON C. AMENT, Victoria; JOHN B. BAUGUSS, Whitewright.

To Washington, D. C., for duty in the office of the Surgeon-General of the *Army, from duty at Camp Travis, Fort Sam Houston,* Texas, Lieut. CLAUDE C. CODY, JR., Houston.

Utah

To Linda Vista, Calif., for temporary duty, Lieut. ONTIE HOVENDEN, Salt Lake City.

Vermont

To Camp Custer, Battle Creek, Mich., for duty, from Fort Benjamin Harrison, Lieut. GEORGE E. LATOUR, Burlington.

To Canal Zone, and report in person to the Governor of the Panama Canal, Balboa Heights, for assignment to duty, Capt. GEORGE G. MARSHALL, Rutland.

Virginia

To Camp Sheridan, Montgomery, Ala., base hospital for duty in the surgical service, Lieut. HERBERT W. ROGERS, Nassawadox.

To Camp Wheeler, Macon, Ga., for duty, from *Fort Oglethorpe,* Lieut. WILLIAM S. WILEY, Bristol.

To Fort Oglethorpe, for instruction, Capt. WILSON E. DRIVER, Norfolk.

To Neurological School, University of Pennsylvania, Philadelphia, for intensive training in brain surgery, Lieuts. JOSEPH F. GEISINGER, ALVAH L. HERRING, FRANK H. REDWOOD, Richmond.

To Newport News, Norfolk, Petersburg, Richmond, Alexandria, Washington, Winchester, *Harrisonburg,* Staunton, Charlottesville, Lynchburg, Roanoke, Pulaski, *Bristol, Lynchburg,* Danville, South Boston, Richmond, Roanoke, for the purpose of examining applicants for appointment in the Medical Reserve Corps of the Army and upon completion of this duty to return to their proper station, Major JOHN G. NELSON, Lieut. JOSEPH T. McKINNEY, *Richmond.*

To Richmond Medical College, Richmond, Va., for a course of instruction in *military roentgenology,* Lieut. JAMES N. WILLIAMS, Clifton Forge.

Washington

To Army Medical School, Washington, D. C., for preparation for nutritional survey, Lieuts. ROLLA B. HILL, Colfax, for instruction, JOSEPH R. TURNER, Tacoma.

To Rockefeller Institute, New York, for a course of instruction in laboratory work, from Army *Medical* School, Capt. AUSTIN U. SIMPSON, Seattle.

West Virginia

To Camp Hancock, Augusta, Ga., for temporary duty, from Fort Oglethorpe, Lieut. CLERMONT E. PARK, Parkersburg.

To Macon, Ga., and report in person to the commanding officer Remount Dept., for duty, Lieut. JOSEPH K. COWHERD, Ridgeley.

Wisconsin

To Camp Hancock, Augusta, Ga., for duty as *member* of a board of medical *officers* for the special examination of the *command* for tuberculosis, *from* Fort Benjamin Harrison, Lieut. ADELOR E. GENDRON, River Falls.

To County Hospital, Chicago, Ill., for instruction *in* military roentgenology, Lieut. MAXIMILIAN W. MOELLER, Milwaukee.

To Neurological School, University of Pennsylvania, Philadelphia, for intensive training in brain surgery, Lieut. *ORVILLE* R. LILLIE, Milwaukee.

ORDERS TO CONTRACT SURGEONS

Arkansas

To Camp Sheridan, Montgomery, Ala., for the purpose of conducting examinations in his specialty, and upon completion of this duty to return to his home, Dr. WILLIAM E. HUGHES, *Pocahontas.*

California

To Walter Reed General Hospital, Washington, D. C., for instruction in tuberculosis examination, Dr. FREDERICK A. BROWN, Hayward.

Colorado

To Camp Doniphan, Fort Sill, Okla., for duty as a member of the tuberculosis examining board, Dr. J. W. CRAIGHEAD, *Denver.*

Connecticut

To Camp Dix, Wrightstown, N. J., *for duty as* member of tuberculosis examining board, Dr. JOSEPH WALSH, New Britain.

To Camp Greene, Charlotte, N. C., for duty as a *member* of medical officers for the examination for *tuberculosis,* from Walter Reed General Hospital, Dr. GEORGE H. JENNINGS, *Jewett City.*

To Camp Wadsworth, Spartanburg, S. C., *from* Walter Reed General Hospital, Takoma Park, D. C., for duty as a member of the tuberculosis examining board, Dr. HUGH F. KEATING, New Haven.

To Walter Reed General Hospital, Takoma Park, D. C., for instruction in tuberculosis examinations, Drs. WILLIAM H. GRAY, Mystic; PATRICK J. CASSIDY, Norwich.

To Walter Reed General Hospital, Takoma Park, D. C., for duty, Dr. PERCY HICKLING, Washington.

Illinois

To Camp Sevier, Greenville, S. C., for duty as *member of the tuberculosis* examining board, Dr. JAMES S. RANKIN, De Kalb.

To Fort Benjamin Harrison for instruction in tuberculosis examination, Drs. WERNER E. EARLANDER, BENEDICT W. ROGERS, Chicago; CLARENCE N. McCUMBER, Lewiston.

Indiana

To Camp Sheridan, Montgomery, Ala., from Fort Benjamin Harrison, for duty as member of tuberculosis examining board, Dr. CHARLES J. McINTYRE, Indianapolis.

To Fort Benjamin Harrison for instruction in tuberculosis examinations, Drs. H. E. WHITLEDGE, Evansville; STEVENS C. MARKLEY, Richmond.

Iowa

To Camp Logan, Houston, Tex., for the purpose of acting as a member of a board of medical officers *for the special* examination *for* tuberculosis, Dr. ROBERT E. CONNIFF, Sioux City.

To Fort Benjamin Harrison for instruction in tuberculosis examination, Dr. ANDREW L. BELT, Fort Dodge.

To Fort Dodge, Des Moines, Ia., 88th Division, as member of board of medical officers for examination for tuberculosis, Drs. WALTER L. BIERRING, ADDISON C. PAGE, E. B. WINNETT, Des Moines.

Louisiana

To Camp Beauregard, Alexandria, La., 38th Division, for duty as member of the tuberculosis examining board, Drs. LEON J. MANVILLE, *Houma;* L. O. CLARK, Lafayette; ROBERT W. O'DONNELL, THOMAS E. WRIGHT, Monroe; WALTER J. DURAL, A. L. LEVIN, New Orleans.

Maryland

To Phipps Clinic, Baltimore, Md., for duty as director in his specialty, Dr. ADOLF MEYER, Baltimore.

To their homes, Drs. EUGENE J. LEOPOLD, A. P. HERRING, Baltimore; J. P. WADE, Cantonsville.

Massachusetts

To Walter Reed General Hospital, Takoma Park, D. C., for instruction in tuberculosis examination, Drs. *JOSEPH A. COGAN, Boston;* L. T. NEWHALL, Brookfield.

Michigan

To Camp MacArthur, Waco, Tex., *32d* Division, for the *purpose of* acting as a member of a board of *medical officers* to examine *for* tuberculosis, Dr. B. A. SHEPARD, *Kalamazoo.*

To Fort Benjamin Harrison, for instruction in tuberculosis examinations, Dr. E. B. PIERCE, Howell.

To State Psychopathic Hospital, Ann Arbor, Mich., for duty as specialist in nervous and mental diseases, *Dr.* ALBERT M. BARRETT, Ann Arbor.

Minnesota

To Des Moines, Ia., Camp Dodge, for duty as member of board of medical officers for tuberculosis examination, from Fort Snelling, Minn., Drs. WALTER J. MARCLAY, HARRY R. *NORDLEY,* Minneapolis.

To Camp Lewis, American Lake, Wash., for purpose *of examining* in his specialty and upon completion of this duty *to return* to his home, Dr. RALPH E. MORRIS, Minneapolis.

To Camp Logan, Houston, *Tex., for duty* as a member *of the tuberculosis* examining board from Fort Snelling, Dr. *ROBINSON* BOSWORTH, St. Paul.

To Fort Snelling, Minn., as roentgenologist, Dr. *CHARLES* A. DONALDSON, *Minneapolis.*

Missouri

To Fort Benjamin Harrison for instruction in tuberculosis examination, Dr. L. T. HALL, Potosi.

To his home from duty at Fort Worth, Tex., Dr. PHILIP COGAN, St. Louis.

New Jersey

To Camp Dix, Wrightstown, N. J., for duty as member of tuberculosis examining board, Dr. MARCUS W. NEWCOMB, Brown Mills.

New Mexico

To Fort Bayard, N. M., Army General Hospital for duty, Dr. H. W. BREWER, Columbus.

To his home from duty at Camp Cody, Dr. E. D. McKINLEY, Alamorordo.

New York

To Camp Sevier, Greenville, S. C., for duty as member of board of medical officers for tuberculosis examinations, Drs. FRANK F. FINNEY, Burke; LEONARD P. SPRAGUE, Chateaugary.

To Camp Upton, Yaphank, L. I., for the purpose of conducting examinations in his specialty, from Camp Mills, L. I., Drs. GLENTWORTH R. BUTLER, TASKER HOWARD, Brooklyn.

To Camp Wadsworth, Spartanburg, S. C., for duty as a member of the tuberculosis examining board, from Walter Reed General Hospital, Dr. PERCIVAL F. DALPHIN, Malone.

To Walter Reed General Hospital, Takoma Park, D. C., for instruction in tuberculosis examination, Drs. HOWARD VAN RENSSELAER, Albany; ALFRED G. WILDING, Malone.

To Washington, D. C., for duty on the Advisory Committee on Venereal Diseases, Dr. GROVER W. WENDE, Buffalo.

To their homes, Drs. T. STUART HART, GEORGE H. KIRBY, ROBERT BURLINGTON, New York City.

North Carolina

To Camp Greene, Charlotte, N. C., from Fort Oglethorpe for duty as member of board of medical officers for special examination for tuberculosis, Dr. F. B. SPENCER, Salisbury.

Ohio

To Fort Benjamin Harrison, for instruction in tuberculosis examination, Dr. E. C. DAVIS, Cleveland.

Oklahoma

To Fort Reno, Okla., for duty, Dr. W. R. MILLER, Calumet.

Oregon

To Camp Lewis, American Lake, Wash., for duty as a member of a board of medical officers for tuberculosis examination, Drs. BRICE R. WALLACE, Albany; GUY L. BOYDEN, Pendleton; C. D. BODINE, NOBLE W. JONES, RAY W. MATSON, RICHARD WELLINGTON, Portland.

Pennsylvania

To Camp Dix, Wrightstown, N. J., for duty as members of tuberculosis examining board, Drs. ALIX H. DAVISSON, J. CLINTON FOLTZ, ELMER H. FUNK, MOSES JACOB, ISADORE KAUFMAN, H. R. M. LANDIS, ROBERT S. McCOMBS, CHARLES M. MONTGOMERY, J. J. ROBRECHT, CLARENCE D. SMITH, Philadelphia.

Camp McClellan, Anniston, Ala., for the purpose of conducting examinations in his specialty and upon completion of this duty to return to his home, Dr. THOMAS C. SIMONTON, Pittsburgh.

To Camp Sevier, Greenville, S. C., for duty as member of the tuberculosis examining board, Dr. G. FRANKLIN BELL, Williamsport.

To Fort Benjamin Harrison, for instruction in tuberculosis examination, Drs. H. J. HARTZ, E. S. VANDER-SLICE, Philadelphia.

To Walter Reed General Hospital, Takoma Park, D. C., Drs. JOHN W. ELLENBERGER, Harrisburg; JACOB ROSENBLOOM, Pittsburgh.

To his home and report by wire to Surgeon-General of the Army upon his arrival, from Camp Wadsworth, Spartanburg, S. C., Dr. WILLIAM C. WALLACE, Ingram.

Rhode Island

To Camp Hancock, Augusta, Ga., from Walter Reed General Hospital, Takoma Park, D. C., for duty as a member of the tuberculosis examining board, Dr. JAY PERKINS, Providence.

Tennessee

To Fort Benjamin Harrison for instruction in tuberculosis examination, Dr. H. P. COILE, Knoxville.

To his home from duty with the Tennessee National Guard, Dr. J. J. NEELY, Memphis.

Texas

To his home from duty at Leon Springs, Tex., Dr. ROBERT G. McCORKLE, San Antonio.

Virginia

To Walter Reed General Hospital, Takoma Park, D. C., for instruction in tuberculosis examination, Dr. FRANK G. SIMMONS, Richmond.

Washington

To Camp Lewis, American Lake, Wash., for duty as member of tuberculosis examining board, Drs. E. R. AHLMAN, Hoquiam; A. B. McLEAN, Pe Ell.

Wisconsin

To Camp MacArthur, Waco, Tex., *32d Division,* for duty as member of tuberculosis examining board, from Camp Robinson, Sparta, Wis., Drs. W. B. FORD, J. D. MADISON, L. G. SYKES, J. G. TAYLOR, Milwaukee.

To Camp Sheridan, Montgomery, Ala., for duty as member of tuberculosis examining board, Dr. THOMAS MILLER, Oconomowoc.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; *such as relate to society activities, new hospitals, education, public health, etc.*)

ARIZONA

New Members of Board of Examiners.—Dr. Coit Hughes, Phoenix, has been appointed a member of the State Board of Medical Examiners to succeed Dr. Ira E. Huffman, Tucson; Dr. Albert L. Gustetter, Nogales, to succeed Charles T. Sturgeon, Globe, and David L. Conner, Phoenix, to succeed Dr. George W. Martin, Tucson.

Personal.—Dr. Franklin C. Norman, Hayden, has been appointed superintendent of the State Hospital for the Insane, Phoenix, succeeding Dr. John R. Walls, Tucson, resigned. ——Dr. J. Bernard Nelson, Mesa, has been appointed superintendent of public health of the state, succeeding Dr. Robert N. Looney, Prescott.——Dr. Allen H. Williams has succeeded the late Dr. Harry J. James as medical director of St. Luke's Home for Tuberculosis, Phoenix. Dr. Marian Walker Williams, wife of Dr. Allen Williams, has been made assistant director.

ARKANSAS

Venereal Clinic.—A free clinic for venereal diseases has been opened in the Medical School of the University of Arkansas, Little Rock, by Drs. Sterling P. Bond, Claude C. Pierce, U. S. P. H. S., Augustus C. Shipp and Mr. H. H. Railey. The clinic is open each day from 12:30 to 2.

FLORIDA

Hospital Site.—Drs. J. Edward Smoak and Mack R. Winton have purchased, for $10,000, a site for a hospital, 32 by 110 feet, at Bravard and Grand Central avenues, Tampa.

Antituberculosis Campaign.—Plans for a general campaign throughout the state were discussed at the meeting of the executive committee of the Florida Antituberculosis Association, September 19. Dr. Carrol H. Frink, secretary of the association, presided.

Trachoma in Florida.—A number of cases of trachoma have appeared in Riverside and other sections of the state, and Dr. William H. Cox, Brooksville, state health officer, has requested the Surgeon-General of the United States Public Health Service to detail an officer to aid in combating the disease. Dr. John McMullen, U. S. P. H. S., has been detailed to this duty.

ILLINOIS

Diphtheria in Edwardsville.—Dr. John J. McShane of the state board of health is investigating conditions in Edwardsville where twenty-five cases of diphtheria have occurred, with one death.

To Aid Tuberculosis Work in France.—Miss Elizabeth Wallace left Chicago, October 15, for France as a member of the Tuberculosis Commission headed by Dr. Livingston Farrand, president of the University of Colorado, and secretary of the National Association for the Study and Prevention of Tuberculosis.

Personal.—Dr. Frank Billings arrived in Chicago, October 19, after several months spent in Russia as chairman of the American Red Cross Commission.——The wife of Dr. H. Wernicke Gentles, Chicago, disappeared from her home, October 20, while suffering from melancholia, and her body was found in Lake Michigan the next day.——Dr. James A. Day, Jacksonville, announces his removal to Springfield.

Tuberculosis Clinics.—Two special clinics were given, October 12 and 13, at the Chicago Municipal Tuberculosis Sanatorium by Dr. H. Kennon Dunham, Cincinnati, who spoke on "The Interpretation of Roentgen-Ray Photographs of the Lungs in Tuberculosis," and by Dr. William Snow Miller of the University of Wisconsin, Madison, who spoke on "The Anatomy of the Lungs." The clinics were attended by present and former members of the staff of the sanatorium and its dispensary, and by the class of the Chicago School of Military Roentgenology.

Chicago

Canadian Surgeon-General to Address Institute of Medicine.—Surgeon-General Fotheringham of the Canadian Army will address the Institute of Medicine of Chicago on Friday, Nov. 2, 1917, in the LaSalle Hotel, at 8 p. m. Surgeon-General Fotheringham went to France in 1914, with the first Canadian contingent, and was in active service in France with the Canadian forces until April of this year, when he was promoted to the Department of Militia and Defense, Ottawa, as Surgeon-General of Canada.

The subject of his address will be "Modern Methods in War from a Medical Standpoint."

IOWA

Personal.—Dr. Arthur A. Schmidt, Postville, while driving his automobile over a grade crossing near Postville, was struck by a train. The automobile was destroyed, and Dr. Schmidt sustained a broken arm, fracture of the nose and internal injuries.

MARYLAND

Personal.—Dr. Archibald C. Harrison, Baltimore, director of the University of Maryland Base Hospital Unit, was operated on at St. Joseph's Hospital, October 7, for disease of the abdomen and is reported to be doing well.——Dr. George M. Fischer, Spring Gap, has been appointed justice of peace for Allegany County.

New Tuberculosis Hospitals Proposed.—Dr. John D. Blake, health commissioner of Baltimore, in a recent report of the heads of the department, mentioned the great number of deaths due to tuberculosis among the negroes in Baltimore, and attributed this to the fact that there is no hospital at which they can be treated, and they are carrying the disease into the homes of the white people. Mayor Preston stated that he contemplated building two hospitals in the near future, one for whites and another for colored persons.

Meetings.—The semiannual meeting of the Medical and Chirurgical Faculty of Maryland will be held on October 31 at Havre de Grace. Dr. Purnell F. Sappington, Bel Air, president of the Harford County Medical Society, will deliver the address of welcome. Dr. Guy Steele, president of the Medical and Chirurgical Faculty, will speak on "Pellagra in Maryland." Dr. Herbert Harlan of Baltimore will read a paper on "Proposed Changes in the Medical Practice Act," and Dr. Arthur P. Herring, secretary of the state lunacy commission, will address the meeting on "Psychiatric Problems of the War."

Hospital rates Increased.—Representatives from all the hospitals in Baltimore appeared before the board of estimates recently and showed that it is impossible to treat city patients sent to the hospitals by supervisors of city charities at the existing rate of 62½ cents a patient per day, because of the high cost of food, medicine, gauze and coal. The city was asked to pay the hospitals next year $1.75 a patient a day. Dr. Charles O'Donovan, who represented St. Joseph's Hospital, said that it cost that hospital to maintain and treat a patient sent by the city $1.55½ a day. St. Joseph's from Oct. 1, 1916, to Oct. 1, 1917, has spent on city patients $56,000, and 1,723 patients were sent to the hospital by the city authorities for treatment during that time. Dr. Alexius McGlannan, who represented St. Agnes' and Mercy hospitals, stated that it costs those hospitals $1.50 a day to maintain and treat a patient. Dr. Randolph Winslow of the Maryland General Hospital placed the cost of city patients in that hospital from $1.50 to $1.60 a day. Similar statements were made by Dr. G. Milton Linthicum of the University Hospital; Dr. Smith of Mercy Hospital, and Dr. Albert T. Chambers of the Franklin Square Hospital. Dr. Linthicum pointed out to the board that the city officials should take good care of the hospitals so that the poor patients sent for treatment might be given proper care. It was hinted by all the physicians present that unless the city pays more money for the poor patients sent for treatment, the work will have to be curtailed or stopped altogether.

MINNESOTA

Diphtheria at State Hospital.—The epidemic of diphtheria which began about July 15, at the State Hospital for the Insane, Rochester, has now subsided. There were about 250 cases, with no deaths.

Southern Minnesota Physicians to Meet.—The annual meeting of the Southern Minnesota Physicians' Association will be held at Mankato, November 26 and 27, under the presidency of Dr. Aaron F. Schmitt, Mankato.

Good Work at Sanatorium.—The state board of control received a report from the State Sanatorium for Tuberculosis, Owatonna, which says that thirty-five patients had been discharged, cured, from the institution during September. Of these, thirty have gained an average of 40½ pounds during their stay at the institution.

Personal.—Prof. C. C. Palmer of the College of Agriculture of the State University has been appointed head of the department of bacteriology, physiology and hygiene, at the Delaware College, Newark, Del.——Dr. Frederick M. Allen of the Rockefeller Institution, New York, delivered an address for the University of Minnesota Medical Society at Minneapolis, October 8, on "Diabetes."——Dr. Charles E. Smith has resigned as medical inspector in the St. Paul Health Department, to accept a position with the state department of health. ——Dr. Harry G. Irvine, Minneapolis, has been appointed director of the State Bureau of Venereal Diseases of California.

New State Officers.—At the annual meeting of the Minnesota State Medical Association, held in St. Paul, October 10-12, under the presidency of Dr. Harper M. Workman, Tracy, the following officers were elected: president, Dr. Arthur J. Gillette, St. Paul; vice presidents, Drs. Ora C. Strickler, New Ulm; Edward H. Frost, Willmar, and Matthew J. Lynch, Minneapolis; secretary, Dr. Thomas S. McDavitt, St. Paul (reelected); treasurer, Dr. Earle R. Hare, Minneapolis; councillor, for the sixth district, Dr. Frank R. Weiser, Windom, and for the eighth district, Dr. Hugh F. McGaughey, Winona; delegate to the American Medical Association, Dr. George D. Head, Minneapolis, and alternate, Dr. John W. Ball, Minneapolis. Resolutions were adopted by the association urging the establishment of a safety zone around Fort Snelling, and the enactment of laws for the control of venereal diseases by the state board of health.

MISSOURI

Personal.—Dr. Wilson J. Ferguson, Sedalia, recently appointed a member of the state board of health, was elected vice president of the board, September 29.——Dr. Woodson Moss, Columbia, has retired from the faculty of the University of Missouri, after a service of forty-three years.

St. Louis

Emergency Unit Organized.—A medical unit of thirty physicians and surgeons has been organized by the St. Louis Medical Society to cooperate with the home guard regiments for service in case of emergencies, such as the recent race roits in East St. Louis, Ill.

Cleared of Disloyalty Charge.—The St. Louis Medical Society, at its meeting, September 23, exonerated Dr. R. Emmet Kane of a charge of disloyalty, made by several members of the auxiliary Medical Defense Committee, and extends an honorable vote of thanks to Dr. Kane for his "untiring and patriotic medical work since the war began."

Personal.—Dr. Charles W. Shery has been appointed city bacteriologist and pathologist, succeeding Dr. Frederick A. Baldwin, resigned.——Dr. George W. Flynn sustained severe cuts and bruises when a city ambulance collided with his automobile, October 5.——Dr. Aden C. Vickrey was found unconscious beside his automobile, September 22, with a fracture of the base of the skull, and is under treatment in the Alexian Brothers Hospital.

Registration Subcommittee Appointed.—The Auxiliary Medical Defense Committee of St. Louis has appointed a subcommittee for the registration of medical practice, consisting of Drs. Willard Bartlett, N. M. Freund and G. A. Jordan. The committee has formulated plans to insure that competent physicians will take case of the practice of any medical men volunteering for Army and Navy service with the provision that from one third to one half of any fees collected should be turned over to the family, or deposited to the physician's credit.

MONTANA

Hygienic Laboratory Opened.—The hygienic laboratory of the state board of health at the state capitol, Helena, was opened, October 15, under the charge of Dr. Arthur H. McCray.

State Board Election.—At the October meeting of the State Board of Medical Examiners in Helena, Dr. Sidney A. Cooney, Helena, took his seat as a member of the board, and was elected secretary, succeeding Dr. William C. Riddell, resigned. Dr. Patrick H. McCarthy, Butte, was elected president.

Hospital News.—Work will be commenced soon on the new Deaconess Hospital, Billings. The necessary fund of $10,000 has been oversubscribed, and a 10-acre site has been secured between Lewiston and Alderson avenues; the contract has been awarded.——An addition has been made to the Park Hospital, Livingston, at a cost of $20,000. This addition increases the capacity of the hospital by twenty rooms, and will accommodate fifty patients.

NEW MEXICO

Personal.—Dr. Miguel F. Des Marais, superintendent of the New Mexico Hospital for the Insane, East Las Vegas, has resigned.——Dr. Samuel H. Eckles, Miami, Ariz., has succeeded Dr. Edward W. Hooper, Silver City, resigned, as physician of Grant County. Dr. Eckles has been ordered to report for duty in New York City, November 15, and expects to be sent abroad.——Dr. LeRoy S. Peters has disposed of his interest in the Albuquerque Sanatorium, and has been appointed associate medical director of St. Joseph's Sanatorium, Albuquerque.

State Society Meeting.—The annual meeting of the New Mexico Medical Society was held at Las Cruces the first week in October, and the following officers were elected: president, Dr. John W. Kinsinger, Roswell; president elect, Dr. Charles A. Frank, Albuquerque; vice presidents, Drs. Hugh V. Fall, Roswell; Chester Russell, Artesia, and Howard M. Cornell, Las Cruces; secretary, Dr. Robert E. McBride, Las Cruces; treasurer, Dr. Frank E. Tull, Albuquerque; delegate to the American Medical Association, Dr. Harry A. Miller, Clovis; alternate, Dr. Robert E. McBride, Las Cruces, and councillors, first district, Dr. Robert L. Bradley, Roswell; second district, Dr. Harry A. Miller, Clovis; third district, Dr. Walter E. Kaser, Las Vegas; fourth district, Dr. Charles H. Churchill, Madrid; fifth district, Dr. George S. McLandress, Albuquerque, and sixth district, Dr. Troy C. Sexton, Las Cruces. Albuquerque was selected as the next place of meeting.

NEW YORK

Centennial of Medical Society.—The one hundredth anniversary of the Steuben County Medical Society was celebrated at Bath, October 16. The presidential address on "Our Centennial Anniversary," was delivered by Dr. Henry J. Wynkoop, Bath.

District Society Meetings.—The Sixth District Branch of the Medical Society of the State of New York held its eleventh annual meeting at Glenn Springs, October 9, and elected the following officers: president, Dr. R. Paul Higgins, Cortland; vice presidents, Drs. John M. Quirk, Montour Falls, and Leon M. Kysor, Hornell; secretary, Dr. Charles H. Gallagher, Ithaca, and treasurer, Dr. Stuart B. Blakely, Binghamton.——At the eleventh annual meeting of the Seventh District Branch of the Medical Society of the State of New York, held in Canandaigua, September 27, Dr. John Pratt, Manchester, was elected president; Drs. J. Polk Delaney, Geneva, and Festus M. Chaffee, Middlesex, were elected vice presidents; Dr. John F. Myers, Sodus, was elected secretary, and Dr. Alfred W. Armstrong, Canandaigua, treasurer.

New Adjustment of Medical Claims Under Compensation Act.—The State Industrial Commission has issued a statement announcing changes in procedure on claims for medical compensation to injured employees. Hereafter all claims for medical services must be made direct to the commission, which will pass upon the claims, make awards covering medical services in amounts that may be deemed reasonable, and issue an order directing payment which, if not obeyed, may be filed in the county clerk's office and become a judgment of the Supreme Court. This change has been made as the result of a recent decision of Justice Benedict in the Appellate Division of the Supreme Court, which has established in effect that no action can be maintained in the courts for medical services, but that the matter must be determined by the commission, which establishes both the reasonableness of the amount and the location of the liability. If the employee provides his own medical attention he will be obliged to meet the expense, and the doctor may have a lien on the compensation to be paid.

New York City

Case of Anthrax at Bellevue.—A victim of anthrax died recently in Bellevue Hospital. This was the sixth case of anthrax which has been cared for at Bellevue within a brief period. Among the six cases there was *one* recovery.

Harvey Lecture.—The first lecture of the Harvey Society series delivered at the New York Academy of Medicine, October 27, by Prof. W. T. Porter of Harvard University, took up the question of "Shock; Observations at the Front."

New Brooklyn Hospital.—The cornerstone of the new hospital building which is to replace the Cumberland Street Hospital was laid on the afternoon of October 18, by Mayor Mitchell and Comptroller Prendergast. The new structure is to cost $800,000, and the contract calls for its completion within a year.

Lectures on Skin Diseases.—The governors of the New York Skin and Cancer Hospital announce that Dr. L. Duncan Bulkley, assisted by the attending staff, will give the nineteenth series of clinical lectures on diseases of the skin in the outpatient hall of the hospital on Wednesday afternoons, beginning November 7, at 4:15 o'clock.

Anniversary Dinner of Pharmacy College.—The Brooklyn College of Pharmacy will celebrate its twenty-fifth anniversary by a dinner to be given at the Elk's Club, Brooklyn, November 21. The dinner is in honor of two members of the faculty, Profs. D. C. Mangan, and H. D. Schimpf, who have completed twenty-five years of continuous service.

Ambulance Wrecked by Trolley.—As the result of a collision with a trolley car at Forty-Sixth Street and Fifth Avenue, Brooklyn, on October 14, a Norwegian Hospital ambulance was wrecked. The ambulance surgeon, Dr. John M. Tamraz, and the driver sustained minor injuries. No patient was in the ambulance at the time of the accident.

Psychiatric Changes.—On October 1, the State Hospital Commission appointed Dr. Kirby, formerly director of clinical psychiatry at the Manhattan State Hospital and recently medical inspector of the New York state hospitals, director of the Psychiatric Institute, Ward's Island. Dr. Kirby has also been appointed professor of psychiatry at the Cornell University Medical College, succeeding Dr. August Hoch, who has resigned and will remove to California.

Free Clinic for Speech Defects.—Financed by public-spirited citizens of New York, a New York Clinic for Speech Defects has been incorporated, with Dr. Herbert L. Wheeler as president. The clinic will be open this month, under the medical direction of Dr. James Sonnett Greene, and among the members of the consulting board are Drs. Abraham Jacobi, John MacKenty, Phillip D. Kerrison and George M. Parker. In addition to the task of restoring the former powers of speech to soldiers rendered mute by shellshot, the board will develop the treatment of inherited or acquired speech defects.

Hospitals Face Large Deficit.—According to the report of the United Hospital Fund for the fiscal year ending September 30, forty-six of the large hospitals that share in this fund are facing a deficit that will total over $1,000,000. Estimates compiled by the fund show that in 1917 the expenses of these forty-six prominent hospitals were $6,862,359, and their total income only $6,371,832, leaving a deficit of over $490,000. For the year just ended there was a further deficit of $700,000, and several of the large hospitals have not yet sent in full returns but state that their deficits are the largest in their history. The New York Hospital has reported a deficit of $96,812; the German Hospital, $52,724; the Volunteer, $40,377; the Nursery and Child, $60,539; Polyclinic, $21,430; Lying-In, $19,416.

Medical Experiences at Camp Upton.—The Base Hospital, Seventy-Seventh Division, National Army, Camp Upton, Long Island, furnished the program of the Section on Medicine of the New York Academy of Medicine at the regular meeting of October 16. The program included a description of the complicated administration of an army base hospital by Major J. D. Whitham. A paper on the "First Psychiatric Experiences in the National Army" was read by Dr. Aaron J. Rosanoff which brought out the fact that the examination of recruits has shown a much larger number of individuals with psychopathic conditions than has been hitherto recognized, and that many such cases that might pass under a doctor's care in civil life without their mental condition being diagnosed were sifted out by the routine examinations and longer periods of observation in vogue in the Army. Dr. Abraham Zingher gave a talk on the "Schick Reaction in Recruits of the National Army," in which he stated that out of several thousand men subjected to the Schick test 85 per cent. were found immune to diphtheria. The application of the Schick test would leave only about 15 per cent. of the troops to be watched for diphtheria, would materially assist in making a diagnosis of diphtheria in doubtful cases, and would result in a great saving of diphtheria antitoxin. Dr. Russell L. Cecil spoke on the "Reactions Produced by Prophylactic Inoculation with the So-Called Triple Typhoid Vaccine." In his experience only an average of one man in every 1,000 inoculated suffered from a reaction [illegible] ntly severe [illegible] send him to the hospital, and even then his stay in the hospital was very short, frequently only twenty-four hours. He found the reactions from the use of the triple vaccines no more frequent or severe than those from the typhoid vaccine alone.

PENNSYLVANIA

Philadelphia

Veterinarians Mobilize.—Dr. Clarence J. Marshall, state veterinarian and professor of veterinary medicine at the University of Pennsylvania, has gone to Washington to supervise the mobilization of the government's veterinary service. There are 12,000 experts and enlisted men in force.

Jefferson Unit in New Quarters.—The Jefferson Base Hospital Unit No. 38, under Major John S. Lambie, has entered new quarters at the Second Regiment Armory. Here Major William M. L. Coplin and Capt. Frank H. Hustead have their offices. The 152 men of the personnel of the unit will receive hospital training in the city institutions, and learn cooking in the hotels.

Medical Club Nominations.—At the meeting of the Medical Club of Philadelphia, October 19, the following nominations were made: president, Drs. Albert P. Brubaker and William D. Robinson; first vice president, Dr. G. Oram Ring; second vice president, Dr. Alexander McAllister; secretary, Dr. William S. Wray; treasurer, Dr. Lewis H. Adler, Jr., and governor, Dr. McCluney Radcliffe.

Hospital Opens New Office.—The Pennsylvania Committee (Medical Section) of the Council of National Defense has opened its office in City Hall. An information bureau has been established with a view to supplying institutional vacancies as they may occur with medical men, in the capacity either of interns or of visiting physicians. Vacancies in private practice will also be filled whenever possible.

Personals.—Dr. D. Randall MacCarroll has been elected to fill the vacancy on the obstetric staff of the Maternity Hospital caused by the resignation of Dr. Charles C. Norris.——Major S. MacCuen Smith has been relieved from active duty at Camp Meade, and has returned to Philadelphia.——Dr. D. Gregg Metheny has returned to Philadelphia from Newport, R. I., where he has been in the service of the United States Navy. Dr. Metheny has been temporarily detached from active service in order to resume his duties at the Jefferson Medical College.——Dr. Frank C. Hammond, who is connected with the Samaritan Hospital, has been appointed a member of the board of health, to serve during the absence in France of Dr. Alexander C. Abbott, who entered the Army Medical Corps several months ago.——Dr. Hubley R. Owen, chief of police surgeons, who enlisted as first lieutenant in the Jefferson Hospital unit, which will leave for France, the early part of 1918, was granted an indefinite leave of absence. No successor has been chosen for Dr. Owen.——Dr. Clement A. Fogerty, who left for England early in August, has been promoted to the position of assistant surgeon in the Southwark Hospital, London.——Dr. Mary Ridegway, who was severely burned when a lamp exploded and threw burning oil on her face and arms, is in a serious condition.

VERMONT

Bennington County Physicians Elect Officers.—At the annual meeting of the Bennington County Medical Society, held at Manchester Center, Dr. John I. Cochran, East Dorset, was elected president; Dr. James L. Lovejoy, Manchester Depot, vice president, and Dr. L. H. Ross, Bennington, secretary-treasurer. At this meeting Dr. Schuyler W. Hammond of Rutland discussed the "Allen Treatment for Diabetes Mellitus."

New State Officers.—The Vermont State Medical Society held its one hundred and fourth annual meeting in Barre, October 11 and 12, under the presidency of Dr. Clarence H. Beecher, Burlington, and elected the following officers: president, Dr. Clayton W. Bartlett, Bennington; vice president, Dr. William Lindsay, Montpelier; secretary, Dr. William G. Ricker, St. Johnsbury (reelected); treasurer, Dr. Edward H. Martin, Middlebury; auditor, Dr. Waldo J. Upton, St. Albans, and councilor for first district, Dr. James N. Jenne, Burlington, and for the second district, Dr. Frank E. Farmer, St. Johnsbury. Burlington was selected as the next place of meeting.

TEXAS

Quarantine Station.—A committee representing Beaumont, Port Arthur and Sabine has gone to Austin to endeavor to secure an additional appropriation of $15,000 from the legislature for the construction of the proposed state quarantine station at Sabine.

Personal.—Dr. Albert H. Braden, Beaumont, has been appointed chief director for the International Board of the Rockefeller Foundation, and will be in charge of the health and sanitary survey to be conducted throughout the state.——Dr. William E. Howard, Dallas, has been elected surgeon of the United Spanish War Veterans.

New Officers.—At the semiannual meeting of the South Texas District Medical Association, held in Beaumont, October 12, Dr. James E. Thompson, Galveston, was elected president; Dr. Wil T. Williams, Beaumont, vice president, and Dr. Albert H. Braden, Beaumont, secretary-treasurer. Houston was selected as the next place of meeting.——At the annual meeting of the Dallas Association for the Study and Prevention of Tuberculosis, October 10, Dr. Robert B. McBride was elected president, and Dr. Raleigh W. Baird, vice president.——At the fifth annual meeting of the Texas Surgical Society, held in Houston, October 8 and 9, the following officers were elected: president, Dr. W. Burton Thorning; vice presidents, Drs. Frank Paschel, San Antonio, and Andrew B. Small, Dallas; secretary, Dr. Frank L. Binds, Houston; treasurer, Dr. J. B. Smoot, Dallas, and recorder, Dr. Judson L. Taylor, Houston. Waco was selected as the next place of meeting.

CANADA

Medical Officers Decorated.—The following Canadian Medical officers have been invested by King George with the military cross: Capts. Walter Lawson, Hugh Mustard and Frederick Pees.

Hospital News.—Major D. W. Whitton is appointed to command a hospital ship.——Lieut.-Col. E. J. Williams is appointed to command the Canadian hospital at Hastings, England, succeeding Lieut.-Col. Hugh E. Munroe.——The accommodation at Camp Hill Military Hospital, Halifax, N. S., is to be increased by the addition of two new wings. It will then have a capacity of 600 beds.——The Military Annex of the Vancouver General Hospital was formally opened, September 15. The buildings has accommodation for 300 patients, there being eight wards, each containing from thirty-four to forty beds.

Army Medical News.—Temporary Brig.-Gen. Auckland Campbell Geddes, M.D., Montreal, has had conferred on him the honor of Knight Commander of the Order of the Bath. Dr. Geddes is director of recruiting in England. Sir Auckland C. Geddes had occupied the chair of anatomy in McGill University a year when war broke out. He is a brother of Sir Erie Geddes, First Lord of the Admiralty.——The Military Cross has been awarded the following officers of the Canadian Army Medical Corps: Capts. Ronald Hugh Macdonald, Winnipeg; Robert James Manion, Fort William, Ont; Archibald McCausland, and Capt. Ashley C. Cooper Johnston, Lundbreck, Alberta.

Medical Boards in Ontario.—Nine medical boards will be stationed in the Province of Ontario. Of these, three will be located in London, one each in Windsor, Sarnia, Harriston, Guelph and Brantford, and there will be one traveling board. These boards will examine the drafted men, and a central board will be located at Ottawa to review the cases passed on by the local boards.——A second army medical board has been established in Windsor, Ont., composed of Captain Walsh, Guelph; Lieutenants Ross, London and Brisson, Tilbury. The first board is composed of Capts. W. Gallow, Goderich; G. Murray Flock, and Major W. A. Burgess, Windsor.

Personal.—Dr. William D. Brydone-Jack, Vancouver, B. C., has been appointed superintending engineer of the public works department for the provinces of Manitoba and Saskatchewan.——Dr. Arthur C. Nash, Vancouver, has been appointed resident physician and medical officer of health at Massett, Queen Charlotte Islands.——Major Andrew MacPhail, A. D. M. S., London, England, is returning to his home in Montreal. Dr. MacPhail has been overseas two and one-half years, and will be assigned to duty in Canada. He is editor of the *Canadian Medical Association Journal*. Major John S. Jenkins, Charlottetown, P. E. I., succeeds him.——Lieut.-Col. Henry R. Casgrain, Windsor, Ont., who has been in command of Bushey Park Red Cross Hospital, England, has been appointed to command the French-Canadian Hospital at St. Cloud, near Paris, France.

Lieutenant-Colonel Lebel, who was in command, will probably return to Canada. Lieutenant-Colonel McQueen, late of the Fifth Field Ambulance, will succeed Colonel Casgrain in command of Bushey Park.

GENERAL

Southern Gastro-Enterologists to Meet.—The next annual meeting of the Southern Gastro-Enterological Association will be held at Memphis, Tenn., November 12, under the presidency of Dr. James C. Johnson, Atlanta, Ga.

Tuberculosis Foes Elect Officers.—At the closing session of the fifth Mississippi Valley Conference on Tuberculosis, held in St. Paul, October 10, Dr. Alfred Henry, Indianapolis, was elected president; Dr. Walter J. Marcley, Minneapolis, vice president, and Mr. James Minnick, Chicago, was reelected secretary.

Anesthetists Elect Officers.—At the annual meeting of the Interstate Annual Meeting of Anesthetists, held in Toledo, Ohio, October 11, Dr. Elmer J. McKesson, Toledo, was elected president; Dr. John J. Buettner, Syracuse, N. Y., vice president, and Dr. F. Hoeffer McMechan, Avon Lake, Ohio, secretary-treasurer.

National Board Examination.—The third examination of the National Board of Medical Examiners was held in Chicago, October 10-18. Twenty-eight candidates were examined, of whom twenty-two passed. Arrangements have already been made for another examination, which will be held at the Bellevue Hospital, New York City, Jan. 9-17, 1918.

New Mississippi Valley Officers.—At the annual meeting of the Mississippi Valley Medical Association, held in Toledo, Ohio, October 9 to 11, Dr. Francis M. Pottenger, Monrovia, Calif., was elected president; Dr. Frank B. Wynn, Indianapolis, vice president; Dr. Henry Enos Tuley, Louisville, secretary (reelected); Dr. Samuel C. Stanton, Chicago, treasurer (reelected). Louisville, Ky., was selected as the next place of meeting.

Bequests and Donations.—The following bequests and donations have recently been announced:

Columbia University, Mt. Sinai Hospital, United Hebrew Charities, and Montefiore Home, each $5,000; Home for Aged and Infirm Hebrews, St. John's Guild and Society for Improving the Condition of the Poor, New York City, each $2,500 by the will of Isaac Newton Seligman.

Johns Hopkins University, Baltimore, and the Charity Organization of New York, each $100,000, and one half of the residuary legacies of four beneficiaries by the will of Jennie Gillender.

Red Cross First Aid Trip.—The Central Safety Committee of the Missouri Pacific Railway Company has arranged with the American Red Cross Society for the Red Cross First Aid Car No. 2 in which Dr. Eric S. Green, Washington, D. C., is to make a trip along its lines for the purpose of instructing employees and their families in first aid for the injured and the means of preventing accidents. Dr. Green will deliver lectures and make demonstrations. The trip began October 9, at St. Louis, and will end December 23, at Texarkana, Ark.

Southwestern Physicians Elect Officers.—The Medical Association of the Southwest held its annual meeting in Kansas City, October 15 to 17, under the presidency of Dr. Everett S. Lain, Oklahoma City, and elected the following officers: president, Dr. Edward H. Martin, Hot Springs, Ark.; vice presidents, Drs. C. Lester Hall, Kansas City, Mo.; James M. Bonham, Hobart, Okla.; Matthew M. Smith, Dallas, Texas, and Ernest F. Day, Arkansas City, Kan., and secretary, Dr. Fred H. Clark, El Reno, Okla. (reelected). The next meeting will be held in Dallas, Texas.

Prevention of Infant Mortality.—At the annual meeting of the American Association for the Prevention of Infant Mortality, held in Richmond, Va., October 15 to 17, under the presidency of Dr. William C. Woodward, Washington, D. C., the following officers were elected: president, Mrs. William Lowell Putnam, Boston; president-elect, Dr. Philip Van Ingen, New York City; vice presidents, Drs. Isaac A Abt, Chicago, and Watson S. Rankin, Raleigh, N. C.; secretary, Dr. Henry F. Helmholz, Chicago; treasurer Mrs. Austin McLanahan, Baltimore, and executive secretary, Miss Gertrude B. Knipp, Baltimore.

New Officers for Railway Surgeons' Association.—At the fourteenth annual meeting of the American Association of Railway Surgeons, held in Chicago, October 17 to 19, under the presidency of Dr. William B. Malone, Memphis, Tenn., the following officers were elected: president, Dr. Edwin S. McDonald, Cameron, Mo.; vice presidents, Drs. Jacob Hinden, Strong, Kan.; Francis L. Reder, St. Louis, and Robert McConaughy, York, Neb.; secretary, Dr. Louis J. Mitchell, Chicago (reelected for the twentieth year); treasurer, Dr. Henry B. Jennings, Council Bluffs, Iowa (reelected for the tenth year), and members of the executive board, Drs. Guy G. Dowdall, Chicago, and Joseph R. Hollowbush, Rock Island, Ill. Chicago was selected as the next place of meeting.

Hospital Standardization.—The most important event connected with the recent meeting of the American College of Surgeons and the Clinical Congress of Surgeons was the meeting devoted to hospital standardization. A large number of papers were presented covering the whole subject of hospitals, hospital standardization and the efficiency of hospital work, as well as, and more important, the control of operative procedures. As an outcome of the deliberations it was decided to make an inspection of the various hospitals in the early future, and a committee was appointed to report on the method of procedure. This committee was to report on Friday. It consisted of Dr. E. A. Codman, Boston; Dr. A. J. Ochsner, Chicago, and Mr. John G. Bowman, the director of the college. From the Carnegie Foundation a fund of $50,000 has been received with which to carry on this investigation. A complete report will appear in Society Proceedings next week.

FOREIGN

Peruvian Commission to the United States.—The Peruvian Medical Commission, which will tour the United States inspecting medical schools and hospitals, began its work in Baltimore, October 14, and from there went to Philadelphia and New York. The commission is composed of Prof. Dr. Guillermo Gastaneta and Drs. E. Campodonico and R. Asplazu. The object of the commission is to secure information for the reorganization of the medical schools of Peru after American standards.

Annual Meeting of the Internists of Italy.—It is announced that the twenty-sixth annual meeting of the Italian Societa di medicina interna is to be held during the latter part of October in some city near the firing line. The themes appointed for discussion are camp jaundice, malaria, soldier's heart, kidney disease and tuberculosis in their relations to the military service, and the sympathetic syndromes in soldiers. The secretary of the congress is Prof. A. Berti of Padua.

Deaths in the Profession Abroad.—**R. Oppenheim,** one of the editors of the *Progrès médical,* chief of an ambulance at Vichy, and author of numerous works on the suprarenals and shell shock, aged 43.——**A. Stahl,** at one time president of the Porto Rico Medical Association, and dean of the profession in Porto Rico, aged 79.——**R. del V. Rodriguez,** Porto Rico.——**F. Moser,** a prominent physician in Switzerland; on account of the absence on military duty of the other physicians in his vicinity, he disregarded pneumonia in himself to attend to urgent calls, aged 53.

Annual Meeting of the Porto Rico Medical Society.—This meeting is to be held at San Juan, Porto Rico, December 22 and 23. One evening is to be devoted to a public lecture on the care of infants. The president of the society is Dr. G. Villaronga of Ponce, and the secretary, Dr. A. R. Laugier of San Juan. The bulletin published in Spanish by the society is a fine monthly of about fifty or sixty pages. The leading article is on the hygiene of the home, the writer, Dr. Atiles, urging his medical hearers, among other points, to make every effort to combat certain superstitions still rife in Porto Rico, such as that cobwebs should never be disturbed or bad luck will follow.

LONDON LETTER

London, Oct. 2, 1917.

The War

THE SHORTAGE OF MEDICAL STUDENTS

The effect of medical students' joining the army either as combatants or as members of the medical corps in the early part of the war has been described in The Journal. The position that has now been reached is well summarized in a memorandum submitted to the government by the committee of reference of the Royal Colleges of Physicians and Surgeons (a body appointed to deal with the problem of medical recruiting). The annual average wastage of physicians in normal times preceding the war owing to death, retirement from practice, or permanent incapacity was about 900. The average number of physicians added to the Medical Register annually was about 1,100. There is now a large abnormal wastage in physicians arising directly out of the war. The supply of physicians to meet the needs of the civil population has been reduced to the lowest number *consistent with safety*, and there is practically no reserve to make good the normal annual wastage from deaths or incapacity. All new additions to the ranks of the medical profession by the qualification of students are at once *requisitioned by* the army and are not available, therefore, to make good the *normal* average wastage of physicians required for the civil population. The number of fifth-year men students due to qualify in 1917 *(922) is only barely* sufficient to make good the normal wastage in the profession of that year. The number of fourth-year men students due to qualify during 1918 was 1,078. This number has been reduced since these statistics were obtained, by some of the men's having accepted commissions as probationary surgeons in the navy, and the number who will actually qualify in 1918 is *probably only* just sufficient to meet the normal annual wastage, that is, about 900. The number of third-year *men students* due *to* qualify during 1919 is only 519, and if the greater number of these qualify in due course they will little more than meet half the *normal wastage. There were 783 second-year men* students due to qualify in 1920, and 1,432 first-year men students due to qualify in 1921. *But since these figures* were compiled, the situation has undergone considerable alteration because medical *students who were rejected* as *not fit for* general military service have been called up on the introduction of a series of grades of physical fitness under which men of inferior physique are accepted for military work of a kind suitable to them, and also because first-year students as *they have reached the age of* 18 have been called up. The number of first-year students due to qualify in 1921 is therefore probably at present not more than half the figure given above, and the number of second-year students is less, though probably not to quite the same extent. The average number of medical students registered in times preceding the war was about 1,800 *a year.* The shortage, *therefore, of first*, second and third-year students, as compared with normal times, is a reduction by about two thirds. *In regard* to probationer surgeons in the navy, the committee recommends that these (*who for the most part are fourth or fifth-year men) should* be demobilized *after six* months of service, for otherwise their qualification is being indefinitely postponed. In order to enable this to be done, it is necessary that a supply of junior students as they pass their second *medical* examination should be available, and some of these could become surgeon probationers, and thus make it possible to demobilize those who have served six months. The Central Medical War Committee therefore strongly recommends that medical students now serving in the navy or army as officers or privates should be demobilized to continue their studies, and further, that the calling up of more medical students that have completed their first year of study should cease.

AMERICAN MEDICAL OFFICERS IN ENGLAND

American Army surgeons continue to arrive in this country and take up duty in the military hospitals of London and the provinces as well as in France. There are now over 900 serving with the British forces in Great Britain and France. In addition, during the past year there has been a constant stream of American civilian physicians drafted into our hospitals. The arrangement *has a* double advantage. It relieves the drain *on the* civil medical profession in this country and it gives our *American* colleagues the opportunity of gaining experience of the wounds of modern warfare which, no doubt, they will later turn to account in treating their own soldiers.

The replacement of part-time and in some cases whole-time civilian physicians employed in military *hospitals by* American surgeons has given rise to some *resentment* in consequence of the curt manner *in which the change* was announced by the War Office. There is *no question* as to the American surgeons' being *perfectly* welcomed by their British colleagues as well as by the country at *large*. The British surgeons were simply given a week's *notice that* their services were no longer required by the War *Office*, and they were *not* even thanked, although many of them had made *sacrifices* in order to undertake the work. *The War Office* no doubt finds justification for the immediate *employment* of American surgeons by the fact that the Central *Medical* War Committee has informed it that no more *physicians* can be called up for the army without seriously endangering the supply for the treatment of the civil community. *However*, the replacement has taken place in districts in which there is no shortage of physicians. The mistake made by *the* War Office consisted in not consulting *the professional* committees as to the places where this could be *done with* the greatest advantage to the civil community. *The tendency*, of course, of military authorities everywhere is to give orders and not to try to satisfy or take into account the opinions of persons concerned.

CAMPAIGN AGAINST VENEREAL DISEASE

Considerable progress has been made with the organization of measures for the provision of free diagnosis and treat*ment for persons* suffering from venereal diseases, or suspected to be suffering from them. Between 140 and 150 hospitals in England and Wales have expressed their willingness to participate in the schemes of local authorities, and although *in* a few instances the authorities of important hospitals have been reluctant to inaugurate during the war any fresh arrangements for the treatment of these diseases, this hesita*tion has* been overcome in some cases. The shortage of medical staff and the pressure on the accommodation at most hospitals have presented obstacles. The former difficulty has been met to some extent by the Army Council's arranging that certain officers of the Army Medical Corps specially skilled in the treatment of venereal diseases should devote part of their time to the work of the clinics provided at general hospitals for the treatment of these diseases. Complete schemes have already been submitted by 115 out of the 145 councils that are charged with the execution of the regulations. The total population of the areas of these councils is about 29,000,000. Eighty-nine schemes, serving a population of about 25,000,000, have been approved, and the work has already started at sixty-two hospitals. It is estimated that the facilities provided at these hospitals will serve a population of at least 18,000,000.

ARTIFICIAL LIMBS FOR SOLDIERS

Great attention is being devoted to providing the best artificial limbs possible for the large number of mutilated men discharged from the army. Mr. John Hodge, *minister of pensions, speaking at a public function*, said that the outstanding ideal before the Pensions Ministry was not the allotment of pensions so much as the restoration to useful citizenship *of mutilated men. Wherever possible* an endeavor would be made to restore men to the full use of *their* limbs, and he was seeking *money from the government for* the purpose of starting a national *experimental* laboratory where we might get as near as *possible* to perfection in artificial limbs. He desired to call to his aid the greatest skill and the greatest inventive faculty that the *country* possessed in order to get the *best artificial* limb possible. Incidentally he mentioned that there were 900,000 pensioners on the books of his department, and that this number was being increased by hundreds every week.

FOOD ECONOMY

In a press interview, Lord Rhondda, the food controller, has announced a fresh campaign to awaken the public to the vital necessity of decreased eating. If *voluntary* measures fail, he will have no compunction in *putting* the nation on compulsory rations. The danger of the food situation lies *not to so much* in the submarine peril as in the world shortage of cereals, meats and fats. The timely action of the United States *government, in strenuously* curtailing food exports to neutral countries, should be of inestimable benefit to the Allies in Europe. But the tightening of the blockade is a two-edged sword. Imports of *bacon* and other products into the United *Kingdom from* Denmark *are* thereby bound to be seriously reduced. This *throws* us more than ever on the North American continent for *our* supplies. What we ask from the United States and Canada we cannot procure elsewhere. Unless the Allies in *Europe are* able to import the supplies necessary *for* feeding their *armies* and the civil populations, victory may slip *from* our united *grasp*. During the forthcoming twelve months, our minimum requirements in foodstuffs from the United States and *Canada* will amount to over 10,000,000 tons, and will *represent an* expenditure, without freight charges, *exceeding* $1,250,000,000 *or* roughly speaking, between 3 and 4 million *dollars* a day. Most of this will be for the purchase of cereals, *hog products*, sugar and meat. Several steps have *recently* been taken with a view to closer cooperation. The *first* is the formation by France, Italy and the British *government* of a meats and fats executive, on the lines of *the wheat* executive, which since last October has been buying in the United States and Canada all the wheat required by the Allies. *In* the future all *purchases*, by the Allies, of bacon, ham, lard, butter and cheese in the United States will be pooled through this newly formed executive, thus *eliminating* competitive buying between the Allies, which inevitably tended to raise prices on the North American continent and at home. Several thousand tons of bacon have been bought within the last few days. Executives to pool purchases, by the Allies, of other foodstuffs may be established before long. A special mission, representing the Ministry of Food, will shortly leave for New York to set up the permanent organization for the meats and fats executive to take up with Mr. Hoover on the spot those matters that vitally affect us, and to keep us informed of developments in the United States and Canada. A long stride has been taken toward the stability of the sugar trade. The difficulty of providing shipping for sugar from the East has been largely responsible for a world shortage, with increased competition—and consequent high prices—for the Cuban crop. Mr. Hoover suggested that purchases of Cuban sugar should be centralized in a committee to sit in New York, on which Great Britain should have two delegates. As to prices, while Lord Rhondda admits that we are paying to the United States and Canada today for all our most important imported foodstuffs more than double what we paid before the war, he expresses his confidence that Mr. Hoover and Mr. Hanna are taking steps similar to those taken in this country to limit the profits derived from the food industries. Sir Arthur Yapp, director of food economy, has issued through the religious press an appeal to the churches, asking for their support and for the display of Christian patriotism in the direction of the conservation of food.

A Ministry of Public Health

As foreshadowed in previous letters to The Journal, draft legislation for the creation of a ministry of public health has been submitted to the government. Among the many problems that will face the government after the war, that of health and the cure of disease is one of the most important. The whole tendency of recent years is for the state to employ the medical profession more and more. Commencing with health officers, there were instituted in succession factory surgeons, school medical officers and tuberculosis medical officers. Finally came the insurance act, which transformed most of the physicians of the country into part-time state employees. During the last ten years the government has shown great and increasing activity in promoting maternity and infant welfare. Thus we have reached a stage in which an enormous amount of treatment is given by the state, either gratuitously or partly gratuitously. Like the institutions of this country in general, the various departments concerned with public health have grown up as the necessity arose, and were not created according to any theoretically elaborated plan. The result is a want of coordination and some consequent overlapping of the work of the departments. These disadvantages would be overcome by a ministry of health which would take charge of the whole field. But its establishment will encounter many difficulties because of the various interests involved. The insurance act authorities who represent the great friendly societies have certain views which probably diverge from those of the local government authorities, who now administer health legislation. The medical profession, again, has its own ideals, and views with alarm the increasing activity of the state, which may in the end reduce physicians to little more than state officials. A ministry of health does not necessarily imply this, but it is a great step which would facilitate the transformation.

A Chair of Tuberculosis

The Edinburgh University Court has instituted a chair of tuberculosis, the first one in this country. Sir Robert Philip, the writer on the treatment of tuberculosis, has been appointed as the first professor. The appointment is appropriate, as he was the founder at Edinburgh in 1887 of the first tuberculosis dispensary in the world. The movement then spread from Edinburgh to the European continent and to America.

PARIS LETTER

Paris, Sept. 27, 1917.

The War

PROTECTION OF THE CHEST AND ABDOMEN OF COMBATANTS

At one of the recent meetings of the Académie de médecine, Dr. Delorme, medical inspector-general of the Service de Santé militaire, presented a communication on this subject. He stated that it was practically impossible to obtain complete and absolute protection of the thorax and abdomen by means of any protective apparatus because of the velocity and penetrating force of the rifle bullets; however, a considerable protection can be given against shell fragments, grenades and shrapnel, because the penetrating force of these missiles is much less than that of bullets. In trench warfare these missiles have, in a measure, replaced the bullet. A thoracico-abdominal protector made of a thin sheet of steel gives as much protection to the internal organs or viscera as does the steel helmet for the skull. Dr. Delorme has not sought to guarantee protection of all the thorax and all of the abdomen, but only those organs which, when wounded or injured, give rise to serious or grave conditions. They are the heart, the large vessels, the hilum of the lung, the lung itself, and the small intestine. The proposed cuirasse or chest protector may be made of a steel plate or of pieces or "leaves" (*feuilles*) of leather. On the basis of experience Delorme prefers the former, and he presented a model which will protect the combatant while he is advancing, as well as when he is lying down in the position of a reclining marksman, the shield being switched from front to back, as may be necessary. The academy appointed a commission to study this question, and its findings, whatever they may be, will be referred to the ministry of war.

TREATMENT OF INFECTED WOUNDS BY IODIZED STARCH

M. Auguste Lumière recently addressed the Académie des sciences on the advantages accruing from the use of iodized starch in the treatment of infected wounds, especially wounds of the soft parts, without the formation of deep fistulas or sinuses which would be inaccessible to the antiseptic. This antiseptic, iodized starch, has given much satisfaction. Wounds have been sterilized in a very short time. In the case of deep wounds of the soft parts without fracture, Lumière has used iodized starch irrigation according to the method of Carrel with great success. For that purpose he has made use of the following solution: soluble starch, 25 gm.; boiling water, 1,000 gm., "solution of iodo-iodurée à 1 per cent.," 50 c.c. This solution contains per liter 0.5 gm. of iodin, and is possessed of an antiseptic power that is equal to that of neutral solution of chlorinated soda. The solution is not irritating to the skin, nor does it injure clothing or bedding. Wounds treated with the solution heal with remarkable rapidity.

CONGRESS OF THE MUTILATED

A new congress, devoted to the study of the interesting question of "war injured," will be convened some time during the month of November, 1917. The organizers of the congress are the mutilated themselves, and delegates from all societies now existing in France for the purpose of assisting these men and protecting their interests will be present. A provisional program has been drawn up by the "Société Aide et protection" (society of aid and protection), the oldest of these mutual aid and defense societies. The principal points to be discussed at this congress are the following: raising pensions, and making a new classification of infirmities; questions relating to prosthetic appliances, placing the mutilated, employing reserves, admission requirements, institutions of cooperation, protection and conservation; the question of half pay without pension and the discharged auxiliaries, and the creation of a permanent council of mutilated, which will discuss and arbitrate all the matters in dispute. The address of the secretary of the National Congress of the Mutilated is rue Molière, 15, Paris.

RELIEF OF MEDICAL MEN IN THE ARMY OF THE ORIENT

Deputy Josse, having asked the ministry of war the following questions, (1) why the medical men of the Army of the East are not all treated in the same manner and from the same point of view, namely, the length of service, some having often seen certain of their comrades return to France without being ill, although they themselves have been there more than twenty months, and (2) whether a definite order of leave is obtainable, has received the following response: The relief of the officers of the Service de Santé of the Army of the East is affected according to the conditions provided for and applying in the Armies of the North and Northeast. It is not possible to follow strictly a rule of leave for the return of the personnel of the Army of the East, by reason of the perfect physical condition needed to resist, even under the best conditions, the climate of the Balkan peninsula. The choice of the officers sent to the Army of the East is always made on the basis of youth and health, although volunteers of all ages who can meet the physical requirements are accepted.

RÔLE OF THE AMERICAN RED CROSS

At a recent reunion of the Anglo-American Press Association, Major Murphy, high commissioner of the American Red Cross in Europe, speaking of the *purposes* of this organization, said that whatever may be the character of the American Red Cross in time of peace, he held the firm conviction that today, during this catastrophe, its supreme function is to help in every way possible to win the war. It would be in truth pitiable and despicable to regard its worth as charity alone at a time like this. During the past three years our allies have taken on themselves our part of the fight. They have borne all the burden of the difficulty, they have suffered all the wounds, they alone have died. It is inevitable that some time must pass before our troops can take their part in the trenches. *When the time comes*, the American organizations will demand a like privilege, and will consider it an obligation to do all that lies in their power to help the valiant nations, to whom our people are indebted.

AMERICAN DECORATED BY LEGION OF HONOR

The president of the republic has decided to award the cross of the Legion of Honor to Mrs. Henry Morgenthau, wife of the ex-ambassador of the United States to Constantinople. Mrs. Morgenthau has rendered invaluable service to the French hospital of Constantinople.

IMPROVING WAR BREAD BY NEUTRALIZING THE BRAN FERMENTS

For some time the effort has been made to improve war bread, and this subject has been spoken about often before the Académie des sciences and the Académie de médecine. Notable communications have been made by M. Lapicque, professor in the museum of natural history, and by Dr. Legendre to improve the quality of the bread manufactured from flour bolted at 85 per cent., simply by utilizing lime water in place of ordinary water for kneading the dough. The lime so introduced neutralizes the acidity of the flour containing a considerable proportion of bran, prevents the fermentation of the bread, and assures the best qualities in bread.

The Académie de médecine has appointed a commission to investigate this procedure, and recommend its adoption by the public if it is found to be valuable.

THE WAR AND GENERAL PARALYSIS

The three Paris societies which are devoted to the study of mental diseases, the Société clinque de médecine mentale, the Société medico-psychologique and the Société de psychiatrie, recently held two joint meetings to discuss two important questions in military mental medicine: the discharge of men with general paralysis, and shell shock with its special etiology, evolution and sequels. A whole session was devoted to each of these questions in turn, with M. Justin Godart, undersecretary of state for the military medical service, in the chair at one meeting, and Dr. Simonin, medical inspector, presiding at the second meeting.

The discussion on the discharge of soldiers with general paralysis was brought about by the extremely severe rule voted by the Société de neurologie in December, 1916, on this subject, and by the too literal application of this rule by the medical men entrusted with the task of passing on the candidates for discharge from the army. The society had officially declared that every soldier with general paralysis should be granted discharge No. 2, except when he had been *the victim* of traumatism of the brain, in which case discharge No. 1 should be granted with an incapacity rate of from 10 to 30 per cent.

Dr. Pactet, *in the* leading address, demonstrated that a doctrinal question was responsible for the vote of the Société de neurologie, namely, the belief that general paralysis is exclusively syphilitic in its origin. But to be *syphilitic* is *not* enough to bring on general paralysis. Can any one affirm that the *fatigues*, the emotions, the dangers of the war do not play a part in localizing, aggravating and accelerating the production of the meningo-encephalitis? Instead of regarding *en bloc* all the cases of general paralysis, each should be given a separate examination, and in each individual case the effort should be made *to estimate* the part for which the circumstances of war are responsible, just *as is* being done for the tuberculous. The *military* authorities must be asked for the data as to the services imposed on the patient, *and if* the general paralysis *seems to have* been influenced by them, then grant discharge *No.* 1, with a pretty high rate of *incapacity*. Dr. Lépine, professor of *nervous* and mental diseases at Lyons, declared his views as entirely *in* accordance with those of Dr. Pactet. Dr. *Dupré*, agrégé professor at Paris and hospital physician, insisted on the exclusively syphilitic origin of general paralysis, and *demanded* that discharge No. 1 should be reserved *for* cases in which some grave war mishap could be invoked.

Dr. Marie, physician-in-chief to the public *Asiles* of the Seine department, and Lortat-Jacob, Paris *hospital* physician, gave a description of the general paralysis of wartime as running a much shorter course, with no intermissions, with repeated sudden attacks, and with an early fatal outcome, skipping the stage of helpless dementia. Dr. Vallon, physician-in-chief of the Asile Sainte Anne, reiterated that the interests of the patients must not be sacrificed to too absolute thories—"fragile, like all theories." In the question of discharge *from* the military service, as *in* all medicolegal problems, each case *must* be studied separately, and the men on active service should not be treated any less favorably than workmen becoming paralyzed after an industrial accident.

Dr. Roubinovitch, physician-in-chief of the Bicêtre and Salpêtrière hospitals, expatiated on the lessons to be learned from the Russo-Japanese War, which led to recrudescence of *cases of paretic* dementia in the army. Dr. Colin, physician-in-chief of the insane asylum at Villejuif, presented an array of exact data regarding the cases of general paralysis in *soldiers* that he has had in his charge. He remarked further *that* wounds of the brain are spoken *of always as authorizing* discharge No. 1, but in this connection *it* must be borne in mind that general *paralysis* has never been observed in men wounded in the brain. The physicians on the military discharge commissions interpret in the narrowest sense the term *traumatisme encéphalique*. The restrictions in question will not be applicable to more than a small *proportion of the* patients, not over 15 per cent., the majority of cases being among the territorials, the noncombatants. He then specified *some cases in which* the routine application of discharge No. 2 would constitute a revolting injustice.

The following rule was finally definitely adopted by a unanimous vote. For men with general paralysis, accord discharge No. 2, except in special cases in which a careful inquiry would demonstrate in times of peace, and more especially in time of war, the aggravating influence of military service. The rate of disability should then be from 60 to 80 per cent.

Death of Dr. Legludic

Word has been received of the death of Dr. Legludic, formerly director of the school of medicine and pharmacy of Angers, and physician in chief in the Hôtel-Dieu of that city. Dr. Legludic was 78 years of age.

Marriages

Lieut. Wade H. Fortner, M. R. C., U. S. Army, Princeton, Wis., to Miss Elsie Pineau of Milwaukee, at Fond due Lac, Wis., September 26.

Major Charles Walter Haverkampf, M. C., U. S. Army, Fort Oglethorpe, Ga., to Miss Francis Marion Armitage of Chicago, October 17.

Lieut. Louis Wallace Frank, M. R. C., U. S. Army, to Miss Jean Macdonough, both of Philadelphia, in New York, September 30.

Surg. Irving Whitmore Robbins, U. S. Navy, to Miss Caroline Brandriff Moore of Washington, D. C., at Scarsdale, N. Y., August 21.

Lieut. Charles R. Irving, M. C., W. Va. N. G., Hansford, W. Va., to Miss Elizabeth Logan Bentley of Richmond, Va., September 25.

Clarence Edward Northcutt, M.D., Lexington, Okla., to Miss Marie Robertson of Pauls Valley, Okla., August 30.

Homer Winfield Crane, M.D., Berkeley, Calif., to Miss Jessie Overshiner of Manteca, Calif., October 16.

Forrest Leroy Schumacher, M.D., DuBois, Pa., to Miss Emma Vail of Punxsutawney, Pa., October 3.

Michael Joseph McCarty, M.D., Pottsville, Pa., to Miss Blanche Reilly of Freeland, Pa., October 3.

William Christopher Williams, M.D., to Miss Ethel Mae Hopkins, both of Durham, N. C., October 4.

Julius Raymond Fernandez, M.D., to Miss Agnes E. Pedeaux, both of New Orleans, October 3.

Ward Allen Minor, M.D., to Mrs. Bessie Bogart, both of Utica, N. Y., September 8.

Deaths

William Moore Wright, M.D., Huntingdon, Tenn.; Washington University, St. Louis, 1869; aged 78; formerly a Fellow of the American Medical Association; a member of the Tennessee State Medical Association; a surgeon in the Confederate service throughout the Civil War; a member of the Tennessee Constitutional Convention in 1870; superintendent of prisons in Tennessee from 1871 to 1875; a trustee of the Tennessee Hospital for Insane, Nashville, from 1875 to 1879, and a trustee of the West Tennessee Hospital for the Insane, Bolivar, for several years; died at his home, October 6.

Wyman W. Pilcher, M.D., Warrenton, Ga.; Medical College of Georgia, Augusta, 1893; aged 47; formerly a Fellow of the American Medical Association; a member and president in 1912 and 1913 of the Medical Association of Georgia; one of the most prominent physicians of the South; trustee of the Warrenton Public School; died in the University Hospital, Augusta, October 8, from heart disease.

John Edwin Rigg, M.D., Wilkinsburg, Pa.; College of Physicians and Surgeons, Baltimore, 1879; aged 62; a Fellow of the American Medical Association, and once president of the Allegheny County Medical Society; for two years school director, and for several years president of the local board of health; president of the First National Bank of Wilkinsburg; died at his home, October 3.

James Stifer Gilbert, M.D., Bordentown, N. J.; College of Physicians and Surgeons, Baltimore, 1886; aged 58; formerly a Fellow of the American Medical Association; a member of the Medical Society of New Jersey; from 1896 to 1901 mayor of the city, and later, when Bordentown adopted the commission form of government, continued as mayor; died at his home, October 11.

Melvin Sheldon, M.D., Brooklyn, N. Y.; Albany, N. Y., Medical College, 1893; aged 51; a member of the Medical Society of the State of New York, and for some time a member of the staff of the Samaritan Hospital, Brooklyn; treasurer of the Physicians' Economic League, of Brooklyn; died at his summer home, in Churchtown, N. Y., October 8, from pneumonia.

Albert Preston Tarter, M.D., Alameda, Calif.; University of California, San Francisco, 1882; aged 57; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of California; district surgeon to the Southern Pacific System; died at the Alameda Sanatorium, October 6, after an operation for disease of the intestines.

Earl Micaiah Stewart, M.D., St. Joseph, Mo.; University of Louisville, Ky., 1908; aged 33; formerly assistant surgeon, U. S. P. H. S., and on duty in the Marine Hospital, Louisville, and later surgeon in charge of the Santa Fe Hospital, La Junta, Colo.; died at the home of his parents, in St. Joseph, October 1, from laryngeal tuberculosis.

George W. Bruce, M.D., Moundsville, W. Va.; University of Pennsylvania, Philadelphia, 1848; aged 90; a member of the West Virginia State Medical Association; for several terms a member of the common council of Moundsville, and once mayor of the city; president of the Marshall County Bank; died at his home, October 6.

Hezekiah Gilbert Leigh, Jr., M.D., Petersburg, Va.; Bellevue Hospital Medical College, 1891; aged about 50; a member of the Medical Society of Virginia, and for many years coroner of the city, and surgeon for the Atlantic Coast Line Railway; died, September 22, at Blue Ridge Summit, Pa., from heart disease.

James A. Gibson, M.D., Buffalo, N. Y.; Western University, London, Ont., 1890; aged 50; a Fellow of the American Medical Association; secretary and professor of anatomy in the University of Buffalo; a member of the American Association of Anatomists; died at his home, October 4, from pneumonia.

Fremont C. Jones, M.D., Ebensburg, Pa.; University of Pennsylvania, Philadelphia, 1885; aged 55; formerly a Fellow of the American Medical Association; local surgeon of the Pennsylvania system, and physician to the Cambria County almshouse and jail; died at his home, October 4, from heart disease.

Obadiah Layton Huffman, M.D., Galion, Ohio; Jefferson Medical College, 1894; aged 56; formerly a member of the Ohio State Medical Association; a specialist in diseases of the eye, ear, nose and throat; died while making a professional call near Galion, October 7, from cerebral hemorrhage.

Andrew Baxter Miller, M.D., Chicago; College of Physicians and Surgeons, Chicago, 1898; aged 45; a Fellow of the American Medical Association; professor of clinical gynecology in the Chicago College of Medicine and Surgery; died in his office, October 19, from heart disease.

William Scott Thompson, M.D., Girard, Ohio; Starling Medical College, Columbus, Ohio, 1896; aged 47; formerly a Fellow of the American Medical Association; for many years local health officer; died in St. Elizabeth's Hospital, Girard, October 10, from pleuropneumonia.

John Copestake, M.D., Ames, Iowa; Queen's College, Birmingham, England, 1858; aged 80; a veteran of the Civil War, who was run over by an automobile in Chicago, September 17, died in the Presbyterian Hospital from his injuries, a few hours later.

Harmer M. Newman, M.D., South Milford, Ind.; Rush Medical College, 1886; aged 57; formerly a fellow of the American Medical Association; a member of the Indiana State Medical Association; died at his home, October 12, from nephritis.

Frank Herbert Gardner, M.D., Portland, Me.; Bowdoin Medical School, Brunswick and Portland, 1878; aged 63; formerly a Fellow of the American Medical Association; a member of the Maine Medical Association; died at his home, October 7.

Alfred L. Lafferty, M.D., Las Animas, Colo.; Keokuk Medical College, College of Physicians and Surgeons, 1905; aged 36; formerly a member of the Colorado State Medical Society; died at Howard, Colo., October 5, from tuberculosis.

Will Orvis Scott, M.D., Parish, N. Y.; Albany, N. Y., Medical College, 1891; aged 49; formerly a member of the Medical Society of the State of New York; died in Massena Springs, N. Y., May 24, from chronic parenchymatous nephritis.

Vardaman S. McLellan, M.D., Canton, Miss.; Kentucky School of Medicine, Louisville, 1891; aged 47; a member of the Mississippi State Medical Association; health officer of Madison County; died at his home, September 21, from acute gastritis.

Frederick J. Tischbein, M.D., Cincinnati; Medical College of Ohio, Cincinnati, 1895; aged 45; formerly a member of the Ohio State Medical Association; died at his home in Sedamville, Cincinnati, October 6, from cerebral hemorrhage.

John Byron Burns, M.D., North Yakima, Wash.; Trinity University, Toronto, Ont., 1896, aged 60; formerly a Fellow of the American Medical Association; died at the home of his son in North Yakima, October 4, from heart disease.

Glenn Lazarus Todd, M.D., Jackson, Miss.; Atlanta, Ga., College of Physicians and Surgeons, 1907; aged 35; a member of the Mississippi State Medical Association; was shot and killed in his office in Jackson, October 10.

George Raymond McDonagh, M.D., Toronto, Ont.; University of Toronto, Ont., 1876; L. R. C. P., London, 1877; aged 61; professor of otolaryngology in his alma mater; died at his home, August 26, from pneumonia.

Frederick Phineas Drake, M.D., London, Ont.; Victoria University, Coburg, Ont., 1883; aged 58; associate professor of medicine in the Western University, London, Ont.; died at his home, October 6, from heart disease.

Joseph Francis Somes, M.D., Vincennes, Ind.; Rush Medical College, 1889; aged 53; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; died at his home, September 28.

Arthur Lee Campbell, M.D., Kansas City, Mo.; St. Louis College of Physicians and Surgeons, 1890; Marion-Sims College of Medicine, St. Louis, 1891; aged 49; died in his private hospital in Kansas City, September 27.

Michael Richard Laden, M.D., Hartford, Conn.; New York University, New York City, 1898; aged 43; formerly a Fellow of the American Medical Association; died at his home, August 2, from heat prostration.

John Wesley Stork, M.D., Darmstadt, Ind.; Kentucky School of Medicine, Louisville, 1895; aged 46; a Fellow of the American Medical Association; died at his home, October 1, from cerebral hemorrhage.

Quimbert C. Schuhart, M.D., Rochester, N. Y.; College of Physicians and Surgeons, Baltimore, 1882; aged 61; formerly a member of the Medical Society of the State of New York; died at his home about September 24.

Alfred M. Gamman, M.D., Corning, N. Y.; New York Homeopathic Medical College, New York, 1866; aged 65; a pioneer oil man of Tulsa, Okla.; died in a hospital in Kansas City, October 5, from nephritis.

Harry Morris Capwell, M.D., Meshoppen, Pa.; Temple University, Philadelphia, 1915; formerly an intern in the Robert Packer Hospital, Sayre, Pa.; died at his home, September 22, from pulmonary tuberculosis.

William Urias Truckenmiller, M.D., Allenwood, Pa.; Buffalo University, 1868; aged 76; formerly a member of the Medical Society of the State of Pennsylvania; died on his farm, near Allenwood, September 30.

Wright Hall, M.D., Wilmington, N. C.; Edinborough Medical College, Lumbertown, N. C., 1875; aged 68; a member of the Medical Society of the State of North Carolina; died at his home, September 30.

Nora Soule Davenport, M.D., River Forest, Ill.; Northwestern University, Women's Medical School, Chicago, 1889; aged 72; a Fellow of the American Medical Association; died at her home, October 7.

Daisy Estelle Brown Bonner, M.D., Mount Sterling, Ky.; Woman's Medical College of Pennsylvania, Philadelphia, 1907; aged 38; a colored practitioner; died at her home, August 13, from uremia.

Jonathan Leigh, M.D., Hiawatha, Kan.; Washington University, St. Louis, 1854; aged 100; for sixty years a practitioner of Doniphan County; died at his home, October 9, from heart disease.

Charles H. Nourse, M.D., Darnestown, Md.; Georgetown University, Washington, D. C., 1869; aged 73; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, October 11.

Sarah F. Harris Norris, M.D., Hyde Park, Boston; New England Female Medical College, Boston, 1872; for eight years a medical missionary in Bombay, India; died at her home, October 2.

Joseph Dorpat, M.D., Arapahoe, Neb.; Missouri Medical College, St. Louis, 1875; aged 91; a veteran of the Civil War; died at the home of his daughter in Arapahoe, July 24, from senile debility.

John Henry Ellison, M.D., Altoona, Ala.; University of Tennessee, Nashville, 1888; aged 55; a member of the Medical Association of the State of Alabama; died at his home, September 26.

Jesse W. Hill, M.D., Fort Worth, Texas; University of Pennsylvania, Philadelphia, 1855; aged 84; a Confederate veteran; died at the home of his son, in Fort Worth, September 28.

James Henry Garlick, M.D., Staunton, Va.; Medical College of Virginia, Richmond, 1865; aged 75; a member of the Medical Society of Virginia; died at his home, October 7.

Charles W. Benham, M.D., Vincennes, Ind.; Louisville, Ky., Medical College, 1889; aged 56; a Fellow of the American Medical Association; died at his home, about October 3.

Gilbert Knapp Ellis, M.D., South Sodus, N. Y.; Niagara University, Buffalo, 1886; University of Buffalo, N. Y., 1897; aged 60; died at his home, September 19, from diabetes.

John Raymond Stark, M.D., Indianapolis; Indiana University, Indianapolis, 1913; an honor graduate; aged 26; died suddenly at his home, September 30, from heart disease.

Robert H. Cabell, Chillicothe, Mo. (license, Missouri, 1864); aged 83; formerly a member of the Missouri State Medical Association; died at his home, October 8.

Sebe Duane Austin, M.D., Albuquerque, N. M.; Cleveland College of Physicians and Surgeons, 1910; formerly of Marlboro, Ohio; died in Albuquerque, September 28.

Samuel D. Logan, M.D., Cainesville, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1874; aged 73; died at his home, October 2, from nephritis.

George Wood Jewett, M.D., Brewster, N. Y.; New York University, New York City, 1884; aged 85; died at the home of his grandson, in Brewster, October 4.

William Francis O'Brien, M.D., Pawtucket, R. I.; Tufts College Medical School, Boston, 1904; aged 38; died at his home, August 28, from typhoid fever.

H. C. H. H[illegible]comb, M.D., Ashtabula, Ohio; Philadelphia University of Medicine and Surgery, 1868; aged 74; died at his home, September 23.

A. M. Horner, Laredo, Texas (license, Texas, forty-third judicial district board, 1907); died about September 28.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

"HAINES' GOLDEN TREATMENT"

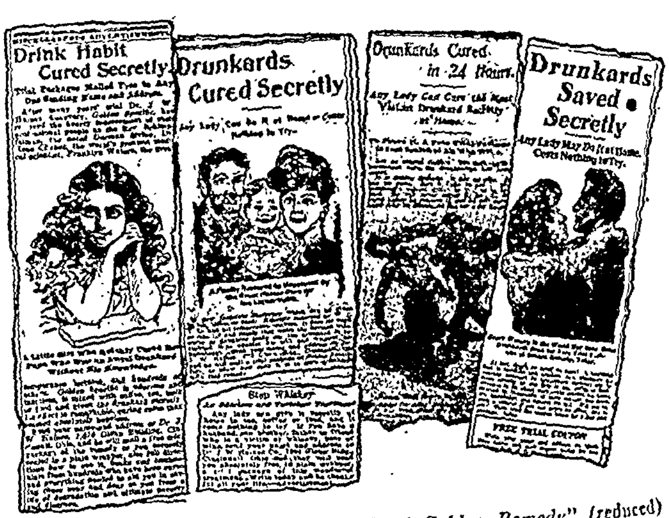
A Cruel Humbug Exploited as a Cure for the Liquor Habit

"Dr. Haines' Golden Treatment" is sold and advertised by the Golden Specific Company of Cincinnati, Ohio. Before lying on the trade package carried with it a risk of prosecution, the "Golden *Treatment*" was sold as "Golden *Specific*." The preparation is one of the numerous fakes exploited as cures for the liquor habit which can be given secretly, curing the alcoholic *in spite of himself*. Here are some of the claims that have been made:

> "Golden Treatment is Odorless and Tasteless—*Any Lady Can Give* It Secretly at Home in Tea, Coffee, or Food."
>
> "Golden Remedy, the Great Home Treatment For Drunkards."
>
> "*Let no woman despair.* The sure quick permanent cure for drunk*ards has been found. It is Golden Remedy.* It has no odor. It has *no taste. Just a little* is put in the drunkard's cup of coffee or tea or in his food. *He will never notice it, he will* be cured before he realizes *it, and he will never* know why he abandoned the *taste for* liquor."
>
> "Golden Remedy has cured some of the most violent cases in a day's time."
>
> ". . . a craving for liquor relieved in thousands of cases without the drinker's knowledge, and against his will."

Any *one* with an *elementary* knowledge of the treatment *of alcoholism knows how cruelly false such claims* as these are. Not only is the statement that the stuff will cure the drunkard "without his knowledge" and "against his will" a falsehood, but it is also a cowardly falsehood in that it deceives those who in the very nature of the case will hesitate to raise any protest against the deception.

The Golden Specific Company advertises that it will send a "free trial package" to any one who will use it. Those who answer the advertisements are sent (1) a form letter so prepared as to simulate an individual communication, (2) a sample of the "Golden Treatment" and (3) a booklet entitled "The National Curse, Drunkenness." The letter, the directions on the *sample treatment*, and especially the booklet all emphasize the *alleged ease* with which drunkards can be cured without their knowledge and against their will. Says the letter: "We are sending *you* a *trial* package of Golden Treatment . . . to *prove to you* how easily and secretly it can be given . . . *without the drunkard* ever *suspecting* that he is being treated at *all*." *And* the booklet: "Many drunkards have been *made* temperate *men* who have taken Golden Treatment in their coffee *without their* knowledge, and today believe *They Quit-Drinking* of Their Own Free Will." And *elsewhere* in the book: "There is *no oppor-*

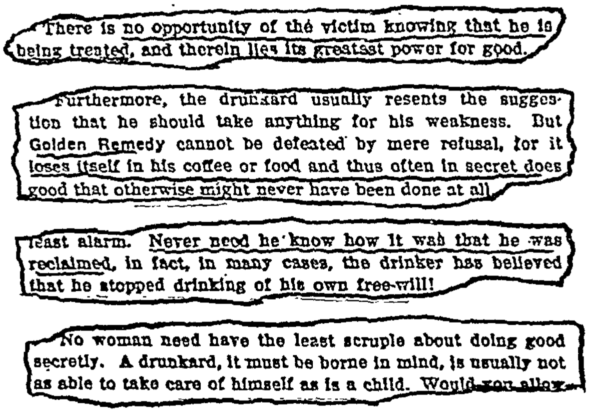


Drink Habit Cured Secretly
Drunkards Cured Secretly
Drunkards Cured in 24 Hours
Drunkards Saved Secretly
FREE TRIAL COUPON

Some typical advertisements of "Haines' Golden *Remedy*" (reduced) of various dates.

tunity of the victim knowing that he is being treated, and therein lies its greatest power for good." On the envelope containing the sample treatment we read: "This is but a trial treatment to show how easily and secretly it may be given . . ." The directions accompanying the sample are very brief, but the recipient is told that "fuller directions and suggestions accompany the full treatment."

Those who send for the "full treatment" (price $3.00) receive a box containing forty powders. The directions accompanying the box are, as was promised on the "trial treatment," much fuller. Moreover there is a marked difference in the attitude of the company toward its victim after it once has received payment for its worthless treatment. The whole trend of the advertising (until the purchase is actually made and the money paid) is that of leading the prospective purchaser to believe that the "treatment" is not only efficacious when given without the knowledge of the patient, but that this is an ideal way to administer it. The directions that accompany the $3.00 package of powders, however, express, or at least imply, doubt as to the probability of success unless the patient is anxious to be cured of his habit and takes the stuff knowingly. "If necessary to administer without the knowledge of the patient . . ."—commence the directions after the victim has paid her money; and: "Whenever it is possible to induce the patient to take the treatment *voluntarily* with a full knowledge of its qualities and effects, it is always the better way . . ." Further, the poor woman, who has purchased this "treatment" in the belief that she can reclaim her husband or brother or father, without his knowledge, is told that "after patient has been under treatment for two days, give sponge (or towel) baths of warm salt water every three days for at least two weeks"! Finally, of course: "If one treatment does not succeed, get another quick."



There is no opportunity of the victim knowing that he is being treated, and therein lies its greatest power for good.

Furthermore, the drunkard usually resents the suggestion that he should take anything for his weakness. But Golden Remedy cannot be defeated by mere refusal, for it loses itself in his coffee or food and thus often in secret does good that otherwise might never have been done at all.

least alarm. Never need he know how it was that he was reclaimed, in fact, in many cases, the drinker has believed that he stopped drinking of his own free-will!

No woman need have the least scruple about doing good secretly. A drunkard, it must be borne in mind, is usually not as able to take care of himself as is a child. Would

Reproductions of clippings from the booklet sent to prospective victims by the Golden Specific Company. Note the emphasis put on the alleged power of the "Golden Remedy" to cure the liquor habit without the knowledge or cooperation of the patient.

Although the worthlessness of this product is obvious it was believed that its composition would be of interest, and an analysis of the stuff was made in the Chemical Laboratory of the Association. The report follows:

LABORATORY REPORT

"Original packages of 'Dr. Haines' Golden Treatment for the Liquor Habit' (price, $3.00 each), prepared by the *Golden Specific Co.*, Cincinnati, O., were submitted to the Chemical Laboratory for examination. Each box contained 40 powders, the average weight of each powder being .75 gm. (11.5 grains). The material had a light brown color, a celery-like odor and a sharp taste. Under the microscope a few starch grains resembling those of ipecac were discerned; wheat starch was present in relatively large amounts. Qualitative tests demonstrated the presence of capsicum, lactose, starch, a small amount of resin and a very small amount of alkaloid. The amount of alkaloid was so small that positive tests could not be obtained for the ipecac alkaloids. Emodin-bearing drugs were not present. The quantitative determinations were ash 1.47 per cent.; moisture (loss at 130°) 4.29 per cent.; lactose 47.5 per cent.; alkaloids 0.0003 per cent.

"From the analysis it appears that Dr. Haines' Golden Treatment is composed essentially of milk sugar, starch, capsicum and a minute amount of ipecac."

Mr. Samuel Hopkins Adams in his series in "The Great American Fraud" devoted one chapter to "The Scavengers." In it he paid his respects to the fakers who professed to cure the drug habit. In the same chapter Mr. Adams discussed the fake liquor-habit cures. In this connection he said:

"The Sunday newspapers and small weeklies teem with advertisements of 'drink cures,' which are supposed to exorcise the alcoholic craving when secretly given in tea or coffee. Few of these concoctions can be described as immediately dangerous, though none of them is really safe. All are swindles. They do not cure the drink habit."

Then Mr. Adams named several preparations of the type he had in mind. In the list was "Dr. Haines' Golden Specific"; it was properly classified.

EFFICIENCY METHODS AND THE PHYSICIAN'S WORK

To the Editor:—How can we, in this time of great demands, accomplish the best work possible with the least expenditure of time and strength? During the last twenty years such experts as Taylor, Gilbreth and Emerson have developed a new science of efficiency, making magician-like changes in the industrial world. Cannot something of this be applied to the physician's work?

Expert studies have proved two facts, and these must be clearly grasped before one can have any sympathetic understanding of this work. First, the average seemingly busy man wastes, daily, solely from inattention and carelessness, an incredible amount of time. Wastages of one to two hours working-time daily are not exceptional but ordinary. Second, processes one repeats over and over, even handed down through generations, do not thereby become perfected, but ossified. Working methods, to be improved, should be persistently studied, analyzed and recorded and the deductions applied. Let us consider a few of the efficiency principles:

1. Efficient Records: The science of quick, accurate, adequate case-recording should be developed. We have many varying systems. Too many of us keep no records at all. Convenient blanks, a good system of symbols, rubber stamps and outlines all need perfecting. More uniformity among workers in similar lines would tend greatly to scientific progress.

2. Standardized Conditions: In large industrial plants, experts are constantly at work planning the simplest details of choice, condition and arrangement of equipment, tools and materials. The physician's office and treatment rooms are, in a sense, a factory in which many complex processes are carried out. As a rule, equipment and arrangement simply grow. The moment's needs are met, and in time we have a helter-skelter mass of stuff with many really needful things lacking. Careful planning and listing of each detail of equipment, beginning with the larger details of office furniture, lighting, etc., the details of dressing-table, laboratory, emergency bag, the filing system for histories, medical journals, catalogs, can well be studied. Such changes simplify one's work and clarify and refresh one's mind. Results are immediate.

3. Standardized Operations: Mr. Frank Gilbreth chanced to see at an exposition an expert girl-operator labeling shoe-polish boxes. After a few minutes' use of his stop-watch he made suggestions whereby her speed increased from twenty boxes in forty seconds to twenty in twenty-six seconds on the first trial; and in twenty seconds on the second. Such results involve use of time and motion studies, methods which are described in the works of these experts and which can be applied to many of the activities of the physician. So routine a process as the questioning of patients can be greatly speeded, made accurate and improved by a few lists of ques-

tions covering routine points, planned and memorized. This does not tend to routinism, but, clarifying best present practices, makes a firm foundation for growth. Sequences of motion and process in all operations from the simplest, such as applying iodin, to the most complex manipulations of the surgeon, would respond well to study and analysis.

4. Written Practice Instructions: In the modern industrial plant each worker, from the highest paid to the lowliest, has his definite printed instructions for each detail of his work. The physician who has worked out a good process, such as a technic for cleansing the ear, giving hypodermic injections, etc., will naturally put this in writing for practice and future improvement. Our chief need here, however, is in good printed instructions for patients. Many of us do, more of us ought to, spend endless hours instructing our "chronics" how to eat, sleep, bathe, exercise, take enemas, cleanse cavities, etc., when such instructions could far better be given in printed slips, adapted for marking to apply to the individual case. Printed instructions are far better than hurried, perfunctory verbal ones.

Much valuable work along this line is now being done for the Medical Department of our Army and some by hospital staffs and the medical staffs of industrial corporations. I believe a general reading of the books in the appended list would prove rewarding, not only in a practical way but as a most interesting record of American ingenuity, persistence and achievement against opposition and discouragement:

Taylor, Frederic W.: Principles of Scientific Management.
Gilbreth, Frank E.: Motion Study.
Emerson, Harrington: Course in Personal Efficiency.
Hudders: Indexing and Filing.
Lewis, St. Elmo: Getting the Most Out of Business.

Stewart Lewis, M.D., Lakehurst, N. J.

THE EARLY RECOGNITION OF MULTIPLE SCLEROSIS

To the Editor:—Neither in a paper read at the last session of the American Medical Association on this subject nor in the discussion, was mention made of a symptom which, if observed early and correctly interpreted, helps very materially in the early recognition of the disease.

When either a chronic or an acute retrobulbar neuritis occurs which cannot be explained by the ordinary causes, especially in a youthful person, a suspicion of a beginning multiple sclerosis must be aroused even though none of the other cardinal symptoms are present. The first symptom of a chronic retrobulbar neuritis is usually an impaired vision; a most characteristic symptom is better vision at night than in the daytime. The cause of this impairment is a central scotoma, at first only for red or green, later absolute, due to the involvement of the papillomuscular bundle of nerve fibers.

Ophthalmoscopically it is possible at times in the early stages to distinguish a blurring of the temporal half of the disk, and later, a pallor; at times no distinguishable ophthalmoscopic signs are present. The commonest cause of a chronic retrobulbar neuritis is a chronic alcohol-tobacco poisoning—the so-called tobacco-alcohol amblyopia. Another frequent cause is diabetes. At times a chronic retrobulbar neuritis is due to occupational poisonings with lead, arsenic, dinitrobenzene, etc. When a retrobulbar neuritis of the chronic toxic type is present, and we are able to rule out tobacco-alcohol poisoning, diabetes or chronic occupational intoxication, a grave suspicion of a beginning multiple sclerosis must be aroused. In an acute retrobulbar neuritis the earliest symptoms are usually severe disturbances of central vision, and pain on moving the eyeball. Ophthalmoscopically the symptoms may vary from slight hyperemia of the nerve head to severe degrees of papillitis.

In the ordinary case of acute retrobulbar neuritis, there is a tendency to quick recovery. When, however, the attack has been a severe one and the nerve badly involved, atrophies, partial or complete, at times ensue.

The commonest cause of an acute retrobulbar neuritis is pus in one of the accessory nasal sinuses, especially in the sphenoidal; the anatomic relation of the sphenoidal sinus to the optic nerve is the cause of this. Almost any of the acute infectious diseases, as well as any form of poisoning, may bring about an acute retrobulbar neuritis.

When an acute retrobulbar neuritis occurs, and these various causes can be ruled out, multiple sclerosis must always be thought of. Bruns and Stolting (*Zeitschrift für Augenheilkunde*, January, 1900) found the optic nerve involved in thirteen out of thirty-eight cases of multiple sclerosis. Anatomic studies showed the pathology to be an interstitial neuritis in various and varying stages. This article first called my attention to the importance of either acute or chronic retrobulbar neuritis as an early symptom of multiple sclerosis. During the past seventeen years I have seen two cases in which this symptom was present when nothing else suggested a possible multiple sclerosis, both of which later developed into well defined cases of that disease.

THE MORAL OBLIGATION OF THE INTERN TO THE HOSPITAL

To the Editor:—I have read with much interest the letter of Dr. Lockwood in regard to the demoralization of hospital interns (The Journal, Oct. 13, 1917, p. 1290). If conditions in his own city are as deplorable as they seem from the perusal of his letter, I believe that much can be accomplished toward improving this regrettable state of affairs by a study of conditions elsewhere. It is usually impracticable in a large city to require those taking an examination for positions of hospital interns to sign a pledge stating that they will take no other hospital internships, if successful in the hospital that requires the pledge. From long experience on examining boards of several hospitals, I have formed the opinion that we must look on the problem from the point of view of the applicant as well as that of the examiner. It has been our custom at the Michael Reese Hospital during recent years to hold an examination at about the same time as that of other hospitals. The position as intern at the Cook County Hospital has always been considered as the greatest honor that an undergraduate could have. This is a matter of tradition which is well deserved and will probably always be so. We have attempted in the past to ask the young men to sign pledges not to take internships in any other hospital, and they have been so frequently broken that we think it best at present to look on the question from the point of view of the student and to permit him to take the Cook County examinations, and if he is successful in the latter, to choose between his Cook County position and our own. At the same time we have attempted through an educational campaign to show the resident staff that our hospital service is almost as good at the present time as the Cook County, and we have been very successful in having our interns recommend our service to various friends in the graduating class, and this more liberal policy has enabled us to omit any pledge. Our positions are taken by those successful candidates who do not prefer the county hospital positions, and the quality has been constantly improving, so that we have today a resident staff that can compare most favorably with that of the county hospital. We thoroughly disapprove of any system of appointing interns, and believe that a competitive examination is the best test, especially if it is combined with an investigation of the character and previous scholarship of the applicant. In Boston and New York the principal hospitals have combined and hold a joint examination for the position of intern, and then permit the successful applicant to take his choice of which hospital he desires to enter.

I am not ready to express an opinion in regard to the value of such a system, owing to a lack of personal experience. A fifth compulsory year, during which every member of the senior class will be obliged to serve a fifth hospital year before his degree will be given, will soon be in force in Illinois, and this will eliminate any friction that now exists. "The unfortunate laxity of professional obligation and duty which hospitals condone" in Dr. Lockwood's letter is one that is not likely to occur if competitive examinations for hospital positions are the rule, and a more liberal policy is pursued by hospitals toward their interns both at the time of examinations, and in giving them better treatment after entrance than many hospitals do at present.

If hospitals will agree not to accept an intern who has not completed his term of service in any other hospital, much of the abuse to which Dr. Lockwood refers, and dishonorable practices arising therefrom, will be abolished. By this I mean that candidates who have begun an intern service in another hospital cannot be lured to leave that hospital by friends who happen to be on another staff of interns, and not be able to get another position if they have been discharged for misbehavior, etc. Daniel N. Eisendrath, M.D., Chicago.

"EXPERIMENTAL PELLAGRA"

To the Editor:—The attention of this office has been called to a statement in the editorial on experimental pellagra (The Journal, Sept. 29, 1917, p. 1082) which is capable of misinterpretation.

McCollom and Pitz are quoted, correctly, as follows: "There is no reason whatever why we should assume, as Voegtlin, Goldberger, Funk and others have done, that pellagra is due to a lack of a specific unidentified dietary factor, a 'vitamin.'"

Neither Professor Voegtlin nor Dr. Goldberger has ever assumed to the exclusion of other possibilities, nor have they stated in any of their publications, that pellagra is due to a lack of a specific vitamin. This was clearly recognized, as were other possibilities; but a perusal of their published work will show that their views on this point have been interpreted erroneously. G. W. McCoy, M.D., Washington, D. C.

Director, Hygienic Laboratory, U. S. P. H. S.

"THE FULL SACRIFICE"

To the Editor:—Your editorial in The Journal, October 20, p. 1355, entitled "The Full Sacrifice," strikes home. I am guilty; and yet I cannot bow gracefully to the charge of neglecting my duty. Surely I have done no bargaining. Indeed, on numerous occasions I have expressed my willingness to do anything I am asked to do. It happens though that in years I am past 55; but in health and strength I am often taken for 40. Except for a partial plate of teeth, I am physically and mentally as fit as I ever was. And in patriotism I am not wanting, for I am American through and through. Besides, I am married to an English woman who has lost many relatives and loved ones in the present war. Now what more do I need to fire me with a spirit of service? True, my specialty is that of obstetrics; but I know other things too. I feel that a man of my experience should be given tasks commensurate with his ability to perform them; yet I am willing to let someone else be the judge of my fitness. You say, "Men of mature age have the glory of choice." I fail to see it. They seem to be denied an opportunity to serve because they are of mature age. Will you not point out a little more clearly how one beyond the age limit can make the full sacrifice?

Fred Elmer Leavitt, M.D., St. Paul.

Casualties on Steam Railways.—For the year ended Dec. 31, 1916, according to *Accident Bulletin 62* of the Interstate Commerce Commission, the total number of casualties on the steam railways of the United States was 206,723, of which 10,001 were fatal. The figures show an increase over the previous year of 1,371 in the number of persons killed and 34,835 in the number injured. Not all of these represent accidents on trains, however, as 525 persons were killed and 129,740 were injured in nontrain accidents, which means those occurring in and around shops, on boats and wharves, at stations, freight houses, engine houses, coaling stations, water stations, tracks, etc., but not accidents occurring directly in connection with operation of trains. Of the number killed in 1916 there were 2,941 employees, 291 passengers and persons carried under contract, and 6,769 other persons, including trespassers and nontrespassers. Of the persons injured, 176,923 were employees, 8,008 passengers and persons carried under contract, and 11,791 other persons.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TRUE ANTIPERISTALSIS IN THE SMALL INTESTINE

To the Editor:—1. What is the consensus of opinion as to the possibility of true antiperistalsis in the small intestine?

2. Kindly cite recent literature on this subject.

Carl A. Dragstedt, M.S., Iowa City, Iowa.

Answer.—1. True antiperistalsis of the small intestine has so far never been observed in man or animals under normal conditions. Antiperistalsis may occur when the small intestine is exposed to the air, or when a portion of the intestine is isolated and subjected to various experimental manipulations. It would also appear that, contrary to the original observations of Mall, a portion of the small intestine that has been resected and sutured in the reversed direction may, after a lapse of several months, show normal antiperistalsis. It has also been shown that antiperistalsis, or something closely akin to it, may occur in intestinal obstruction, and possibly in certain types of stasis. Small particles, like lycopodium spores, introduced in large enemas, may reach the stomach. This has by some been interpreted as evidence of normal antiperistalsis. Boldyreff asserted that antiperistalsis of the duodenum occurred as a normal process whenever the gastric acidity exceeded from 0.25 to 0.30 per cent. But Hicks and Visher showed that the regurgitation of duodenal contents into the stomach under those conditions is not due to antiperistalsis of the duodenum. According to Alvarez, any condition that induces a motor automatism of the jejunum of a higher order than that of the duodenum will lead to antiperistalsis.

BRUCK'S SEROCHEMICAL TEST FOR SYPHILIS

To the Editor:—Kindly publish the technic of Bruck's serochemical test for syphilis, or advise me where I can find it.

R. H. L. Bibb, M.D., Saltillo, Mexico.

Answer.—Nitric acid when added to syphilitic blood serum causes a precipitate to form. Bruck's technic is based on an acid containing, per hundred gm., 24.77 gm. of nitric acid, or, per hundred c.c., 28.48 c.c. of nitric acid with a specific gravity of 1.149. He uses 0.3 c.c. To 0.5 c.c. of clear serum, 2 c.c. of distilled water are added. This is shaken, and then 0.3 c.c. of nitric acid is added with a standardized pipet. This is shaken and permitted to stand at room temperature for ten minutes. Then 16 c.c. of distilled water at 15 C. are added and shaken slowly three or four times so as not to foam. This shaking is repeated ten minutes later, and then the tube is set aside for one-half hour. If the serum is syphilitic it shows a distinct flocculent turbidity. In twelve hours, a precipitate is piled up on the floor of the test tube. If the serum is nonsyphilitic, there is no precipitate at any time. The test is described in the *Münchener medizinische Wochenschrift*, Jan. 2, 1917, p. 25.

DISPOSAL OF COMMISSION ON RECEIVING A HIGHER ONE

To the Editor:—I received a First Lieutenant's commission in the Medical Reserve Corps, Sept. 10, 1917, which I accepted. Under date of Sept. 26, 1917, I received a Captain's commission in the Medical Reserve Corps, which I also accepted. Shall I return the First Lieutenant's commission?

F. M. V.

Answer.—No.

Mississippi June Examination

Dr. W. S. Leathers, secretary of the Mississippi State Board of Health, reports the written examination held at Jackson, June 19-20, 1917. The examination covered 8 subjects and included 64 questions. An average of 75 per cent. was required to pass. Of the 19 candidates examined, 15 passed and 4 failed. Eleven candidates, including 1 osteopath, were licensed through reciprocity. The following colleges were represented:

Oklahoma July Examination

Dr. R. V. Smith, secretary of the Oklahoma State Board of Medical Examiners, reports the oral and written examination held at Oklahoma City, July 10-11, 1917.. The examination covered 11 subjects and included 100 questions. An average of 70 per cent. was required to pass. Of the 21 candidates examined, 18, including 5 osteopaths, passed, and 3, including 1 osteopath, failed. Twenty-five candidates, including 4 osteopaths were licensed through reciprocity and 4 candidates were granted reregistration certificates. The following colleges were represented:.

Business Corporation and Manager Giving Medicine

(Godfrey vs. Medical Society of New York County (N. Y.), 164 N. Y. Supp. 846)

The Supreme Court of New York, Appellate Division, Second Department, reverses a judgment for $2,500 rendered in favor of the plaintiff, who asked damages for an alleged malicious prosecution for having unlawfully practiced medicine without a license, of which he was acquitted. The court says that it regards this case as one of very great importance, as being likely, if it should stand as a precedent as it was, to lead to the opening of many quack sanatoriums and "cure-all" institutes under the guise of business corporations or registered trade-names of individuals not licensed physicians.

The evidence in this case showed that the plaintiff, who was not a physician, had organized, under the business corporations law of New York State, the "Gatlin Institute of New York, Incorporated, . . . to maintain and operate institutes for the cure of the liquor and drug habit." He became and acted throughout as its manager. He purchased from the so-called parent corporation in Chicago the right to use the so-called "Gatlin treatment" for the cure of the drink habit, which consisted for the most part in the taking of a certain liquid medicine and pills, the ingredients of which were unknown to the plaintiff or to any one connected with the New York corporation, the articles being obtained from the said parent corporation or plant. The trial justice properly charged that the New York corporation could not practice medicine; that is, that in that respect it stood the same as an individual. He also properly charged the jury that if the plaintiff, as the manager of the corporation, aided and abetted it in so practicing medicine, he was equally guilty with the corporation itself, which of course is in strict accord with the provisions of Section 2 of the penal law. Still, the court thinks the trial was conducted on an entirely mistaken theory of the law, and that, on the correct theory thereof, probable cause for the criminal prosecution was clearly established. The trial justice conducted the trial and submitted the case to the jury on the theory of law that, if the plaintiff, as manager of the New York corporation, had it treat its patrons, although in its own name, by giving medicine only "on the advice and counsel, or prescription, in the particular case, of a duly licensed physician, it was not practicing medicine, and neither the corporation nor the plaintiff would be guilty of violating the law," which prohibits such practice by any person other than a licensed physician. That the treatment amounted to the practice of medicine by some one cannot be doubted.

Even assuming that the law of the case was correctly declared by the trial justice, as above summarized, the court thinks that probable cause was established for the criminal prosecution because the evidence demonstrated that the advice or prescription of a licensed physician, on which the plaintiff claimed the institute only treated, was a mere sham and pretense. In all instances such prescription was merely treatment by the Gatlin method. There was in the prescription no modification or direction as to time or quantity of the dose, or anything of the sort. The medicine was a secret. Neither the plaintiff nor the physician knew its ingredients. The giving of a prescription by a physician must, of necessity, involve the exercise of judgment as to the particular case, and as well some scientific knowledge of the nature of the medicine prescribed. Here the physician could have possessed no such knowledge, and even the plaintiff, the manager, did not have it. Hence such a prescription was a mere sham and pretense.

On the cross-examination of the physician of the institute, an inquiry to show that he made no analysis or other scientific examination to ascertain the ingredients of the medicine was excluded. This proof was entirely competent to show that the prescriptions given by the physician were pretenses, based on no scientific knowledge.

The court regards the verdict here as directly against a sound and necessary public policy, and is convinced that it should not stand; so the judgment is reversed, with costs; and the complaint dismissed, with costs.

Meaning of the Terms "Physician" and "Medicine"

(People ex rel. Gage vs. Siman et al. (Ill.), 115 N. E. R. 817)

The Supreme Court of Illinois says that a "physician" is one versed in or practicing the art of medicine, and the term is not limited to the disciples of any particular school. The term "medicine" is not limited to substances supposed to possess curative or remedial properties, but has also the meaning of the healing art—the science of preserving health and treating disease for the purpose of cure—whether such treatment involves the use of medicinal substances or not. In common acceptation, any one whose occupation is the treatment of diseases for the purpose of curing them is a physician, and this is the sense in which the term is used in the medical practice act.

The term is not used in any different sense in Section 15 of the vital statistics act, which requires every physician, midwife, undertaker and sexton to register his or her name, address and occupation with the local registrar of the vital statistics district in which he resides. Section 7 of the act directs that the required certificate of death shall be made and signed by the legally qualified physician, if any, last in attendance. The term "legally qualified physician" in this connection is not different in meaning from the term "physician" in Section 15. Each means a physician authorized to practice medicine. The qualification of the physician is only incidentally connected with the subject-matter of the act, which is vital statistics. The state authorizes osteopathic physicians to treat human ailments without the use of medicine and without performing surgical operations, and if a patient dies he cannot be said to have died without medical attendance, so as to authorize the coroner or local registrar to make the certificate of death.

A proviso to Section 3 of the medical practice act declares that only those who are authorized to practice medicine and surgery in all their branches shall call or advertise themselves as physicians or doctors. This proviso was regarded by the counsel for the respondents as sustaining the position that only persons licensed to practice medicine and surgery in all their branches are authorized to issue certificates of death. The proviso is somewhat inconsistent with the provision that treatment for any physical ailment shall constitute the practice of medicine and which authorizes such treatment by persons not authorized to practice medicine and surgery in all their branches. It does not, however, declare that persons treating physical ailments without the use of medicine and without performing surgical operations are not physicians, but only that they shall not call themselves physicians or advertise themselves as such. Whether the legislature can constitutionally prohibit one of these classes from publicly assuming the title of physician or doctor was a question discussed in the brief of the relator which the court does not find it necessary to decide.

This appeal was brought directly to this court on the ground that if the word "physician," in Sections 7 and 15 of the vital statistics act, means only those who are authorized to practice medicine and surgery in all their branches, then to that extent those sections are unconstitutional, and that the proviso to Section 3 of the medical practice act is unconstitutional; but the court does not find it necessary to decide those questions, since it holds that the word "physician," in the vital statistics act, is not limited to any particular school of medicine, but includes osteopathic physicians.

cessation of feeding. I have applied this form of rest cure in many cases, with *restitutio ad integrum*, in the majority of them, and certain relief in all cases, except in malignancy.

DISCUSSION

Dr. Herbert Whitney, Denver: Nothing has been of so much benefit in my practice as the proper observation of the principles of rest and exercise in the treatment of patients with chronic disease.

Dr. H. A. Smith, Delta: The chiropractor, the dietist and the food cranks are getting results in cases that are slipping away from the practitioner of medicine because he does not do one of two things, namely, he either does not go to the trouble of making a diagnosis, or fails to instruct the patient in the matter of diet. If the doctor will regulate the diet of these patients, tell them how much to eat, what to eat, how many meals they should have a day, and the quantity of food for each meal, he will get results in the class of cases in which nutrition is disturbed indirectly.

Dr. M. R. Fox, Sterling: If we paid more attention to rest and exercise, and used a little more "horse-sense," we would get better results.

Dr. Robert Levy, Denver: For many years, superalimentation has been practiced by some of the very best and most reputable authorities in the treatment of tuberculosis. In many instances superalimentation has developed a desire for food, and the patients have improved.

Dr. Julius L. Mortimer, Denver: An effort should be made so to prepare food that it will be inviting and palatable to the patients. I have seen patients eat a great deal more because the food was prepared and served in a most inviting manner, thus stimulating their appetites.

Dr. Kate Lindsay, Boulder: Allen and Josslyn have obtained excellent results in diabetic cases with their methods of treatment simply because they have treated patients individually.

Acute Cholecystitis

Dr. Z. H. McClanahan, Colorado Springs: Drainage is now being employed in a progressively lessening number of cases of gallbladder disease, while cholecystectomy is gaining in frequency of employment in proportionate ratio. As the most frequent site of infection has been shown to be the gallbladder wall, this is a rational change, and cholecystectomy is the rational treatment in the absence of certain contraindications. Pancreatitis contraindicates cholecystectomy. Granting that cholecystectomy is the ideal procedure, drainage still has a field of usefulness in the superlatively acute cases in which the immediate prevention of mortality is of first consideration.

Cholecystectomy Versus Cholecystostomy

Dr. F. N. Cochems and Dr. A. J. Bender, Salida: The definite indications for cholecystectomy are all cases of chronic cholecystitis, injuries, ulcerations, perforations and gangrene of the gallbladder, persistent fistulas and primary malignancy. The advantages are easier convalescence, fewer adhesions, greater percentage of recoveries, diminished recurrences and lower percentage of mortality. The disadvantages are the destruction of the special function of the gallbladder, overlooking common duct stone or stricture. Cholecystostomy would be the operation of choice in many cases of acute cholecystitis, stones in the hepatic and common ducts, acute pancreatitis and when gallstones are accidentally discovered during the course of operations on other abdominal organs.

DISCUSSION

Dr. H. S. Henderson, Grand Junction: I think the pendulum is swinging too far backward. Cholecystectomy is performed more frequently than it should be. Cholecystectomy is indicated when the gallbladder is badly damaged, when its mucous membrane is no longer functioning. In malignant disease the gallbladder should be removed; but the indiscriminate removal of gallbladders because they have stones in them or are inflamed is not good surgery.

Dr. Leonard Freeman, Denver: The consensus of opinion among surgeons today is that cholecystectomy is better than cholecystostomy. It is better to take out the gallbladder than to drain it, provided we can take out the gallbladder with safety to the patient, and that the common bile duct is not obstructed or going to become obstructed. There are cases in which the gallbladder is so badly involved that we are willing to run the risk of taking it out; but such cases are not extremely common. If a patient's condition is such that an attempt to remove the gallbladder increases the risk, the gallbladder should not be touched. If the common bile duct or the cystic duct is obstructed, it should be taken out.

Dr. J. G. Hughes, Greeley: When a drainage operation because of the presence of infection is performed, the chances of healing and recovery of the patient are materially enhanced by the use of autogenous vaccines.

(To be continued)

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Evansville, Sept. 26-28, 1917

The President, Dr. John H. Oliver, Indianapolis, in the Chair

SYMPOSIUM ON DISEASES OF THE GALLBLADDER

Diagnosis

Dr. A. C. Kimberlin, Indianapolis: Owing to a better knowledge of pathology, we have changed our ideas very materially as to the manner in which the infection reaches the gallbladder. We now accept the theory that in most instances it is carried through the blood stream. A certain periodicity in the attacks, and local tenderness may or may not be conspicuous. Neither is jaundice always present. We must know more of the pathology. We do not give enough time to a careful study and analysis of the clinical history.

Medical Treatment

Dr. Charles Sowder, Indianapolis: I would emphasize the necessity for active preventive treatment during the course of and following acute infectious processes which we have determined must furnish the active cause. If we can maintain a normal flow of healthy bile, and by medicinal measures tend to keep the gallbladder sterile, we have taken a long step forward in the prevention of gallbladder disease. We can lay down no hard and fast rule to guide us in treatment. In general, if there is obstruction of the cystic duct resulting in enlargement of the gallbladder, or if repeated attacks of pain or disturbance of digestion render the patient unable to follow his usual vocation, surgical aid should be given. All cases of cholelithiasis with recurring attacks of cholecystitis or pericholecystitis should be subjected to immediate surgical interference. When acute cholecystitis can be ruled out, at least six months' medicinal treatment should be instituted before surgical measures are considered.

Cholecystectomy Versus Cholecystotomy

Dr. H. H. Martin, Laporte: When Rosenow published the results of his experimental work on gallbladder infections, the profession began to realize the limitations of simple drainage of the gallbladder, and to appreciate the cause for so many surgical failures in those cases in which success was legitimately anticipated. Rosenow proved that in the majority of cases, and probably in all, the infection takes place by way of the circulation direct, and that it is the gallbladder walls, and not the bile or the gallbladder mucous membrane, that is primarily involved. Consequently simple drainage fails to relieve many of these patients. Every pathologic gallbladder demanding operative interference should be removed, provided this operation does not add to the mortality rate of a cholecystectomy over a cholecystotomy.

Dr. H. A. Duemling, Fort Wayne: In my opinion, both operations are valuable. Some cases require simply incision and drainage; other patients as certainly must have the gallbladder removed to regain health. We should be very careful in obtaining the history of the patient so that we may make a correct diagnosis; patients, however, are cured not by scientific examination, but by scientific treatment. I do not believe that there ever has been a case of recurrence of stone. Stones do not reform—they are overlooked. This fact led to the exploration of the ducts—a tremendous step forward, and then a new operation appeared—cholecystotomy. Finally, the removal of the gallbladder was advised, but we have not yet reached our goal.

DISCUSSION ON THE GALLBLADDER

Dr. Thomas B. Noble, Indianapolis: Gallstone disease, as it is commonly referred to, is simply an end-product, an ultimate outgrowth of some antecedent happening or accident in the way of infection, or fault in the habit of life of the individual. Cholecystectomy and cholecystotomy are both valuable procedures. They each have their specific indications. I do not believe that every gallbladder requiring operative interference should be removed. The important thing is drainage—in every case.

Dr. Charles Stoltz, South Bend: There is no doubt that stones do recur. Stones form in the hepatic and also in the common duct, and we know of cases in which the biliary ducts are filled with stones. The gallbladder should not be removed in every instance. In many cases drainage offers rest for the mucosa and submucosa of the common ducts as well as the biliary ducts.

Dr. J. Rilus Eastman, Indianapolis: It is mischievous to take out a gallbladder simply because it is an attractive operative procedure. If we had to deal with an infection of the gallbladder alone, this would be a very easy question to solve; but I have never seen a badly infected gallbladder that was not associated with infections of the ducts, or with infection of the pancreas. I believe we shall decide more and more to utilize the gallbladder for drainage in such cases.

Dr. Maurice Rosenthal, Fort Wayne: Unfortunately those cases of biliary duct and gallbladder infection which require excision of the gallbladder are the very cases which really require drainage of the ducts. It is quite possible and just as easy to drain the gallducts after removing the gallbladder as to drain them through the gallbladder. Passing a small tube through the stump accomplishes drainage of the ducts very satisfactorily.

Dr. H. O. Pantzer, Indianapolis: The term "gallstone disease" is not comprehensive enough, and represents only a small part of gallbladder disease. Gallstones may be retained a long time without causing any trouble if the gallbladder is normal. It is futile to attempt any medication in cases of gallbladder disease, for living typhoid germs have been found in the gallbladder twenty, even fifty, years after the attack of typhoid.

Dr. A. S. Jaeger, Indianapolis: I do not think all inflammations of the gallbladder are infective, or that this is Rosenow's belief. Undoubtedly the gallbladder is infected in the majority of cases, owing to bacterial activity; but a nonspecific inflammation of the gallbladder will give the same results.

Complications and End-Results of Tonsillectomy and Adenectomy

Dr. J. W. Iddings, Lowell: Specialists in laryngology have a duty to perform in educating the laity and the profession that the tonsil and adenoid operation is not a minor operation, but one which may be attended with severe, even fatal, consequences; that definite indication should be present before it is advised or attempted, and that it should be undertaken with the same care, skill and caution displayed in any major operation.

DISCUSSION

Dr. G. W. Spohn, Elkhart: The technic is not so important as the results. It matters not so much how the tonsils and adenoids are removed, if the work is done correctly, thoroughly, expeditiously and with no injury to the adnexa. The end-results of such work are satisfactory to both patient and physician.

Dr. W. A. Hollis, Hartford City: The danger of pulmonic infection through aspiration of infectious material, or from the ether, or the danger of suffocation from inhalation of solid particles, is greatly exaggerated. If the operation is done in the Trendelenburg position, it is impossible to have such an accident if one is a careful operator.

1. **Immune Response in Renal Tuberculosis.**—Bonime's paper may be summarized as follows: The prognosis in renal tuberculosis up to the present has been unfavorable under the present day method of treatment. Nephrectomy as an operation for the relief of the patient suffering from tuberculosis of the kidney is a failure, for it fails to remove the focus of infection outside of the kidney, leaving the patient liable to extension of the infection to the remaining kidney from the same focus. The tuberculin treatment of renal tuberculosis has not been as satisfactory as the tuberculin treatment of other forms of tuberculosis, (1) because of the inability to make an early diagnosis; (2) because of the production of early damage before the tuberculin treatment was instituted; (3) as a result of the failure to recognize the important rôle that mixed infection plays in the production of symptoms and pathologic processes. Enough has been shown, however, with tuberculin treatment of renal tuberculosis, in fact, to make it almost certain that were it instituted before permanent damage has resulted—in other words, early in the disease—the prognosis of renal tuberculosis would have a far more favorable aspect. Early diagnosis in renal tuberculosis can be accomplished through the tuberculin test alone. Its more frequent use in early symptoms referable to an indefinite lesion anywhere in the urinary tract is absolutely essential to the more hopeful treatment of renal tuberculosis.

2. **Pulse Pressure Test of Cardiovascular System.**—Pulse pressure readings were used by Cashman as a means of estimating the ability of the circulatory system to withstand strain, for it is the additional strain of the surgical ordeal that is responsible for circulatory exhaustion or collapse. His plan was to subject the patient to the strain of work and observe not only the systolic presssures but the diastolic and pulse pressures as well, for the pulse pressure is the head of pressure which is actually driving the blood through the circulatory system, and inasmuch as the cardiovascular system maintains pulse pressure when an additional strain is imposed on it, so much is efficient circulation maintained. The chief value of the test is in the cases in which the force and rhythm are regular or but slightly irregular, the type of case in which the ordinary method of examination does not throw light on the condition of the circulatory apparatus, and the type of case in which surgeons are

liable to blunder. This test signifies the ability of the cardiovascular system to respond to strain at the time the test is made, and it does not signify what portion of the cardiovascular system is at fault. The condition may be due to a permanently damaged heart muscle or cardiovascular system, which is working with very little reserve and which may fail if subjected to sudden strain. On the other hand, the condition may be a temporary one, due to toxemia, exhaustion, or fatigue, but nevertheless this is the type of case that should not be subjected to additional severe strain. How frequently women are worn out from multiple pregnancies, toxemias, and chronic infections suffering from chronic fatigue and exhaustion. If the histories of these patients are gone into carefully it will be found that they tire readily, suffer from dizziness, dyspnea on exertion, weak spells, or slight swelling of the feet and ankles, although the heart appears to be normal by the ordinary methods of examination. These are the patients who have stormy convalescence after abdominal section. Patients with little reserve and who respond so poorly to light strain should be subjected to neither a severe operation nor a cross-country run as an elective procedure. Cashman describes his method of procedure in detail.

3. **Acute Appendicitis.**—There were thirty-four deaths, or a mortality of 6.8 per cent., among the 500 cases analyzed by the authors. Twice as many died who were operated on the third day after the onset of symptoms as on any other day of the illness. The mortality of those under 10 years and over 50 is 23 per cent. as opposed to a mortality of 4.7 per cent. for those between. Complications were found in 151 persons, or 30 per cent. There were 107 cases of appendicular abscess, or 21 per cent. The mortality was 5.7 per cent. There were forty-five instances of diffuse peritonitis, or 9 per cent. Twenty-one, or 47 per cent., of these patients died. Fecal fistula occurred twenty-four times, an incidence of 5 per cent.; four patients died, a mortality of 17 per cent. Pneumonia occurred twelve times, an incidence of 2.5 per cent. There were four fatalities in the series, or 33 per cent. Secondary peritoneal abscess occurred in eleven instances, being present in one patient at operation and ten times as a sequel. Three of these were subphrenic abscesses. Of the eleven cases, four patients died, a mortality of 36 per cent. Only two cases of ileus were found: one was due to adhesions; the other was a paralytic ileus.

A history of previous attacks was obtained in one fourth of the cases. Vomiting was mentioned in the histories of four fifths of the cases. Five per cent. more had nausea without vomiting. Constipation was five times as frequent as diarrhea. A blood count was recorded in 377 of the cases. Neither a normal blood count nor a very high one rules out appendicitis, although such counts are comparatively rare. The mortality was higher among the two extremes and most favorable with a moderate leukocytosis. The relation of the numerical count to the differential count did not appear to have any prognostic significance. Of 117 perforated cases seventeen died, a mortality of 15 per cent. Of 138 cases with gangrene and no perforation nine died, a mortality of 6.5 per cent. Of 180 suppurative cases without either perforation or gangrene four patients died, a mortality of 2 per cent. Thirty per cent. of perforated, 16 per cent. of gangrenous and 10 per cent. of suppurative cases developed abscesses. Twenty-four per cent. of perforated, 8 per cent. of gangrenous, and 1 per cent. of suppurative developed diffuse peritonitis. The incidence of all complications in perforative cases is 61 per cent., in gangrenous 38 per cent., and in suppurative 22 per cent. It appears from this that the danger of a diffuse peritonitis is greater when there is a perforation than when the inflammation spreads through the appendicular wall, for in the latter case there is a better chance of the peritoneum localizing the disease. There were twenty cases, or 4 per cent., in which it was not possible to remove the appendix. All but two of these were in abscess cases. Three of the twenty patients died, a mortality of 15 per cent.

8. **Coagulo Reaction of Syphilitic Serum.**—Uemura is convinced that the coaguloreaction is highly characteristic in the case of syphilitic serum, especially when the elaborated

case of syphilitic serum, especially when the elaborate method described by him is applied, and the sources of possible mistakes are avoided. In many cases this test is said to be distinctly superior to the Wassermann reaction. It is hardly probable that the coaguloreaction will finally supersede the Wassermann reaction; but it does seem calculated both to furnish scientific research with valuable data in regard to the transformation of serum as wrought by syphilis, and also to facilitate the diagnosis of doubtful cases of syphilis, possibly also of certain apparently similar conditions.

9. **Nervous Symptoms of Polycythemia Vera.**—Of ten cases observed by Christian, all but two showed very definite nervous symptoms, and in most the nervous disturbances were the chief cause of the patient's discomfort. These symptoms varied in duration from a few days to many years. The most frequent symptoms were headache and dizziness. Other common symptoms were disturbances of vision, such as easily induced fatigue of the eyes, blurring of vision, scotomas often scintillating, transient blindness, hemianopsia, and diplopia. Disturbances of sensation, particularly paresthesia, occurred. In several patients motor disturbances, such as paresis and paralysis, were seen. The case in which these were transient and recurred is of special interest. The nervous symptoms in some of the patients were sufficiently focal in character to lead to the diagnosis of brain tumor. One case was of special interest in this connection, for during a period of ten years, during which the patient was seen repeatedly by ophthalmologists and neurologists, brain tumor often was suggested as the cause of his symptoms, and no one seems to have suspected the polycythemia until he was admitted to the hospital, and even when the blood count was known it was still thought possible that some of the focal symptoms were due to a cerebral tumor.

Heat Stroke.—All patients with a temperature of 103 F. or over were immediately placed in a tub of tap water, the level of which was just high enough to cover the body except the head, which was supported in a hammock packed with ice. Vigorous friction was applied to the entire body by four or more persons; ice was freely added to the water, the friction being constantly maintained; the temperature was taken rectally every minute. When the temperature reached 102 F. the patient was removed from the bath, wrapped in sheets or blankets, and returned to the ward. Generally 102 F. was reached in ten to thirty minutes. When the patients were returned to the wards their temperature usually continued to fall, frequently reaching subnormal—95 to 97 F. Cardiac stimulants were given freely, strychnin, sodium caffein benzoate, digitalis, strophanthus; an ice bag was placed at the head and chipped ice was given by the mouth. For subnormal temperature external heat was applied. For recurrences in temperatures up to 103, cold packs and alcohol sponges were given; above 103 the patient was again given a cold water friction bath. It was observed that recurrent temperatures could not be reduced as easily as the initial high temperature, and in a few instances the temperature continued to rise in spite of prolonged friction in cold water. For restlessness and convulsions sedatives were used; morphin, chloral hydrate, scopolamin, the bromids and mechanical restraints.

13. **Alpha Iodin in Chronic Heart Block.**—During the examination of a case of chronic heart block Blackford and Willius attempted to increase the idioventricular rate by the administration of large doses of alpha iodin, the active constituent of the thyroid which Kendall has isolated recently. The administration of this drug has been followed in four cases by marked improvement in the patients' nutrition, associated with increased ventricular rate and cessation of the Stokes-Adams syndrome, though one patient has since died. One-half milligram alpha iodin was administered daily. Alpha iodin quickens the idioventricular rate in complete heart block. This is followed by marked subjective relief to the patient. The drug must be pushed to the tolerance of the patient and the dose then reduced to the largest amount that can be taken without discomfort. The auricular rate increases much earlier and to a much higher figure proportionately than the ventricular rate.

26 Infraction of Head of Second and Third Metatarsal Bones; Report of Cases. W. C. Campbell, Memphis, Tenn.—p. 721.

23. **After-Treatment of Infantile Paralysis.**—Lovett believes that if a patient is not paralyzed in all four extremities, as well as back and abdomen, that he can be made to walk in some form or other; that is to say, that if he has one good arm and one leg with some power in it, it does not seem to matter how bad the contractions and deformities may be, so far as walking is concerned, because most of them, except scoliosis, can be remedied so that the patient can get his legs under him. Cases with general involvement of one or both legs, some paralysis perhaps of the abdomen, and perhaps the total loss of one or two muscles, persisting as total paralysis about three months after the attack, belong in the class of possible recovery. The longer tenderness lasts, the more slowly improvement begins, and in these cases the whole scale seems to be set further along. The more erratic and irregular the distribution of the paralysis, the better chance there seems to be for improvement. The most unfavorable cases seem to be those in which there is a pretty complete loss of power on both sides below a definite level. Cases which have a considerable amount of total paralysis persisting after two or three months do not seem, as a rule, to belong in the class of possible complete recovery. Paralysis of the deltoid is a serious proposition, but complete recovery may take place, especially with the use of the platform splint. Paralysis of the abdomen is very frequently overlooked, but, if supported by corsets from the outset, is, in Lovett's opinion, in most cases, amenable to treatment.

24. **Patellar Bone Graft in Knee Excision.**—Galloway uses the patella as a means of assisting fixation and promoting bony union in cases of knee resection. After the joint is exposed a thin flap of bone is raised from the side of each condyle and turned upward, being kept out of the way, if necessary, by a temporary suture or two. Corresponding raw surfaces are created on each side of the head of the tibia, but in the case of this bone the bony flap is immediately cut away. The lower end of the femur and upper end of the tibia are then sawed off in such a plane that when brought together the bones will fit with accurately apposed plane surfaces when the leg is flexed about 15 degrees in relation to the thigh, the direction of the saw cut being further planned so as to secure apposition without any greater lateral deviation of the leg than is present in the sound limb. Only a thin slice of bone should be taken at first, so that the plane of the cut can be altered by the removal of further thin slices should it be found necessary to do this in order to secure an ideal relation of the leg to the thigh. While an assistant steadies the upturned patella by seizing with a lion-jaw forceps the soft tissues in which it is embedded, Galloway next removes the posterior half of the patella with the saw, and a corresponding flat surface is created with the same instrument on the front of the femur and tibia. After bringing the knee into the extended position and accurately fitting the bones together, a small incision is made through the skin on each side of the tibial head, about 1½ inches below the free margin of the bone, through which are driven two 5-inch wire nails in such a direction as to cross each other and nail the bones securely together. The patella is then placed on the bed prepared for it and nailed across the front of the joint, its upper half in contact with the femur and its lower half in contact with the tibia, thus forming a solid bony bridge across both bones. The flaps of bone raised from the femur are then brougth into contact with the raw lateral surfaces on the head of the tibia. With a running suture of catgut, the deeper soft tissues are quickly brought together, the redundant tissues about the center of the flap being removed if found advisable. Plaster is applied to the leg and thigh separately, these two parts of the lower extremity being then connected by three iron brackets which span the region of the joint and permit subsequent dressing if required.

38. **Cerebrospinal Fluid in Poliomyelitis.**—Overholser found that in the early postparalytic stage of anterior poliomyelitis the spinal fluid usually shows a moderate lymphocytosis and a slight to moderate increase in pressure and in globulin content. Fehling's solution is reduced, but this phenomenon is of little diagnostic value. A reasonably constant curve is yielded by Lange's colloidal gold test; this curve has some value in the differential diagnosis. The picture is only fairly constant, and in the absence of positive clinical findings does not justify a diagnosis.

70. **Surgery of Peripheral Nerves.**—Huber says that the question of using autotransplants or homotransplants of nerve segments in preference to heterotransplants, in clinical cases, on the basis of experimental and clinical observations can be decided in favor of autotransplants or homotransplants in case suitable fresh nerves from man are available at the time of the projected operation, but it should be borne in mind, that especially in secondary operations for loss of nerve substance, both the time of the operation and the method used are often a matter of choice. Heterotransplants, transplantation of nerve segments taken from an animal of another species than the one to which the transplant is made, is an operation not to be wholly condemned, since clinical observations and experimental work both justify this operation. Both clinical and experimental observations warrant the deduction that the operation of choice in cases of repair of an injured peripheral nerve, where direct suture cannot be obtained, is the operation of nerve transplantation, especially if autotransplants or homotransplants are available. This may be combined with tubulization by means of fascial sheaths or hardened arteries. Of the methods of tubular suture and tubulization, hardened arteries and tubes of fascia are to be given preference. Experimental observations with other methods do not warant their recommendation.

71. **Prevention of War Deafness.**—The issuance and compulsory use of some preventive, even if it be nothing more than cotton with petrolatum, Guild says, is in the interests of efficiency in the army and of economic importance. Even such small things as ear plugs are of importance if they can serve to keep trained men in active service. The providing of preventives should not be left to the individual soldier. Nor should such preventives as we have be issued only "when demanded" and to those few who realize the danger and know of the preventive, but they should be issued like clothing, rations, ammunition and other equipment; to all the troops, officers and men alike, and their use not left optional but made compulsory when going into action. Like any other preventive, the object of their use is to keep the active service list up and the hospital list down. Guild believes that the increased efficiency of an army using plugs would be many times greater than the cost of the plugs; they would be one of the smallest expense items of all the equipment of a soldier, and the bulk of even large numbers would not be a very noticeable factor in the problem of transporting supplies.

72. **Gangrenous Balanitis.**—The six cases cited by Owen and Martin were examined within one to three days after the sore appeared, all being in the erosive stage, with an abundant discharge of foul pus, moderate edema with slight phimosis, and exquisitely tender ulcers, the largest sore being about the size of a dime. The ulcers were covered with pus and considerable coagulated serum and exudate, beneath which lay a very superficial reddish colored erosion. All showed moderate inguinal adenitis, painless in character. There were no constitutional symptoms. In all of these cases the sore had appeared within four days after exposure. One patient with a history of repeated exposures, but denying coitus in os showed *Spirochacta pallida,* as well as the organisms characteristic of this condition. This case cleared up promptly under salvarsan and local treatment with hydrogen peroxid. Three other cases treated with wet dressings of hydrogen peroxid cleared up within a few days. The remaining two patients were advised to use the same treatment, and presumably cleared, as they failed to return to their attending physician.

73. **Cyanosis and Hyperpnea Seen in Pneumonia.**—Pearce points out that the percentage of carbon dioxid in the alveolar air is not a good guide as to blood acidosis, at least in cardiac disease, pneumonia and congenital heart disease. In the cardiac case a low carbon dioxid alveolar air pressure is a result of the attempt of the respiratory center to prevent its venous carbon dioxid pressure from being unduly raised because of the slow circulation. In pneumonia and congential heart disease, the respiratory center reacts to keep the arterial blood at a normal carbon dioxid tension.

74. **Experimental Asthma in Guinea-Pig.**—It has been shown by Sewall that guinea-pigs, especially after previous sensitization, may react to intranasal instillation of horse serum by the development of respiratory seizures which have the essential characters of bronchial asthma. In some cases an apparent immunity of the respiratory apparatus may be developed while general hypersensitiveness still remains, as proved by the fatal effect of intravenous injection of serum. In most cases the hypersensitiveness of the respiratory apparatus, once acquired, tends eventually to return, at least through a period of thirteen months. Small nasal instillations of serum, 0.04 c.c., not themselves usually capable of inducing asthmatic paroxysms, apparently have a distinctly inhibiting effect on the development of asthma by large instillations, 0.2 c.c., which themselves tend to maintain hypersensitiveness and override resistance. It is an opinion supported by many additional observations, that serum is actually absorbed by the mucous membrane of the nose whenever placed in contact with it and that the immunologic reactions are internal to the surface. The conclusion, emphasized in other papers is here strengthened that in therapeutic prophylaxis better results may probably be expected by choosing a dosage of antigen which just fails to produce an obvious reaction than by one which entails a marked disorder.

76. **Acute Death from Chlorin Poisoning.**—The acute reaction found by Klotz in the lungs of animals exposed to chlorin consisted mainly in an intense congestion with edema and capillary thrombosis. Animals surviving a longer period showed a pulmonary infiltration of inflammatory cells mainly lymphocytes. The acute capillary thrombosis appears of importance in the acute deaths when the concentration of the gas is great. The intense pulmonary edema obtained by

abstracting a thin serum from the pulmonary blood vessels causes an alteration in the quality of the blood and an increase in its viscosity. This dense blood tends to clot spontaneously and is also influenced in this more rapid clotting by the presence of chlorin within the lung. These two factors, increased viscosity and capillary thrombosis, impede the ready flow of blood through the lung and lead to a fall in the arterial blood pressure. Thus, acute chlorin gassing differs materially from other forms of asphyxia.

77. **Blood Picture Following Experimental Splenectomy.**—In a series of twelve rabbits Orr succeeded in producing an anemia by splenectomy which had a duration of sixty or more days, after which time the red blood count and hemoglobin returned to normal. No definite change was produced by splenectomy in the platelet count and coagulation time. Changes in the total white cell count produced by removal of the rabbit's spleen were not constant. The same conclusion applies to the elements in the differential counts, with the exception of the large mononuclears, which were increased in every instance after splenectomy.

3. **Infective Jaundice.**—It would seem to be proved by the authors that there is in the armies in France a type of infective jaundice which is the same in clinical and pathologic features as that described by the Japanese workers, and that this disease is caused by the *Spirochaeta icterohemorrhagiae.* And there is also undoubtedly proof that this same spirochete may cause a similar train of symptoms without the appearance of jaundice. The entire subject of infective jaundice is reviewed by the authors and a complete bibliography is appended to this article.

5. **Combined Vaccination with Multiple Vaccines.**—Tetravaccine No. 1 (T. A. B. C.) prepared by the authors consists of four standardized emulsions mixed together in equal proportions and containing, per cubic centimeter: typhoid, 500 million; paratyphoid A, 250 million; paratyphoid B, 250 million; cholera, 2,000 million. Of this mixture 0.5 c.c. is given under the skin of the arm the first time, and the same or double the amount a week later. Tetravaccine No. 2 (T. A. B. M.) consists of an emulsion in phenolized saline solution (phenol 0.5 per cent., salt solution 0.85 per cent.) of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, and *M. melitensis.* After standardizing the four different vaccines and testing their sterility they are mixed together in equal parts. The vaccine will contain, per cubic centimeter: typhoid, 500 million; paratyphoid A, 250 million; paratyphoid B, 250 million; malta fever, 2,000 million. Of this vaccine 0.5 c.c. is injected subcutaneously in the arm, and a week later the same or double the amount is given. Pentavaccine

No. 1 (T. A. B. C. P.) consists of a phenolized saline emulsion of typhoid, paratyphoid A, and paratyphoid B bacilli, cholera vibrios and plague bacilli. The vaccine is standardized to contain, per cubic centimeter: *B. typhosus*, 500 million; *B. paratyphosus* A, 250 million; *B. paratyphosus* B, 250 million; *V. cholerae*, 2,000 million; *B. pestis*, 500 million. Half a cubic centimeter is given the first time and double the amount a week later. Pentavaccine No. 2 (T. A. B. C. M.) is so standardized that each cubic centimeter contains: typhoid, 500 million; paratyphoid A, 250 million; paratyphoid B, 250 million; cholera, 2,000 million; malta fever, 2,000 million. At the first injection 0.5 c.c. is given and the same or double the dose a week later.

Hexavaccine (T. A. B. C. P. M.) consists of an emulsion in phenolized salt solution (phenol 0.5 per cent., salt solution 0.85 per cent.) of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *V. cholerae*, *B. pestis* and *M. melitensis*. The combined vaccine is standardized so as to contain, per cubic centimeter: *B. typhosus*, 500 million; *B. paratyphosus* A, 250 million; *B. paratyphosus* B, 250 million; *V. cholerae*, 2,000 million; *B. pestis*, 500 million; *M. melitensis*, 2,000 million. The first time 0.5 c.c. is given and the same or double the amount a week later. The authors point out that the inoculation of the combined vaccines is harmless. The reaction is not severe with the exception of those containing *B. pestis*, but even simple plague monovaccines, whatever their method of preparation, give a severe reaction. It is essential to use in the preparation of the vaccines selected strains of the various micro-organisms which have been found by experience to be rich in antigen. This is especially the case as regards *B. paratyphosus* A and *M. melitensis*, some strains of which are very poor in antigen, and when injected give rise to only a small production of antibodies. Combined vaccines are of practical advantage, especially in the case of troops, rendering possible a contemporaneous immunization for several different maladies; this saves a great deal of time, and the men do not suffer the discomfort of a large number of inoculations. To protect the troops against typhoid, paratyphoid A, paratyphoid B, and cholera with the method of ordinary monovaccines in succession, eight inoculations, at least, were necessary, spread over a period of two months; with the tetravaccine (T. A. B. C.) two inoculations only are sufficient, spread over a period of a week.

6. Rupture of Left Bronchus from Trachea.—The injury in this case was caused by a gunner falling from an empty general service limber, whose wheel then passed over his chest. Besides other injuries there was partial separation of the left bronchus from trachea, the tear being through the anterior portion to the extent of two-thirds of the circumference; acute inflammatory reddening of the mucous membrane of both bronchi; inflammatory infiltration of cellular tissue of middle mediastinum; the cartilaginous rings of trachea and bronchi normally flexible and tough. The most striking primary features of the postmortem examination were the profound degree of collapse of the left lung, its acute hemorrhagic state, evidence of the severity of the crushing blow and the acuteness of the pericardial inflammation.

7. Treatment of Vincent's Angina.—The treatment used by Emrys-Roberts consists in the local application of the following lotion:

	gm. or c.c.	
Hydrogenii peroxidi	150	℥ v
Vini ipecacuanhae	12	ʒ iij
Glycerini	15	ʒ v
Aquae ....ad	240	℥ viij

By its use the gingivitis is usually cured in about six days, while the throat condition clears up altogether in from twenty-four to forty-eight hours.

8. Meningococcus of Weichselbaum.—Hort believes he is able to produce direct morphologic evidence that the meningococcus is not a bacterium at all, and that both it and the filterable virus actually represent different phases in the life cycle of an ascomycetic organism which has hitherto been believed to be an involution form of the meningococcus. This communication deals mainly with the morphologic characters of the meningococcus and of its so-called giant forms which represent an ascal stage in the life cycle of an organism allied to the ascomycetes. The ascus may be either large or small, or of any intermediate size (0.2 to 5 microns). The meningococcus of Weichselbaum is an ascospore, derived from the giant meningococcus by a process of endosporulation. Hort says that the true nature of the meningococcus and its alleged giant forms has hitherto been missed because of the practically exclusive use of solid mediums for purposes of identification, and because direct examination of unstained living organisms, including warm stage development in liquid cultures, has not been carried out.

9. Intravenous Injection of Quinin in Malaria.—As 3 grains of the bihydrochlorid contain as much quinin as 4 of the acid hydrobromid, after commencing with 0.5 gm. doses to ascertain whether the patient has any idiosyncrasy toward the drug, up to 12 grains of the bihydrochlorid or 16 grains (approximately 1 gm.) of the acid hydrobromid, in 7.5 and 10 c.c., respectively, of normal saline (making practically 10 per cent. solutions), may be given once daily for at least four days. Rogers advises to supplement the intravenous doses with quinin by the mouth, as the former is likely to be rapidly excreted through the kidneys, a point he is now investigating. In any case prolonged oral administration should follow the more active intravenous medication. Once the resistant relapse producing stages of the malarial parasite have been produced, quinin by intravenous administration is not likely to be so effective, but the vigorous treatment of primary attacks of malaria by intravenous quinin appears to be worthy of careful trial to ascertain if the frequency of subsequent relapses can be reduced. A further material advantage of such early intravenous administration is likely to be that dangerously large infections, which may terminate at any moment in fatal coma under oral administration of quinin, are likely to be rapidly controlled, and the present mortality from malaria to be reduced to practically nothing.

17 Plastic Meatotomy. J. L. Hamilton.—p. 132.
18 Inguinal Hernia; Some Comments on Present Views. C. Bennett.—p. 134.

16. Rectal Crises of Nontabetic Origin.—Both sexes are liable to these attacks, though, in MacLennan's experience, they occur more frequently in males. It has been observed in ages ranging from 16 to 50. The pain complained of is of the most commanding character; it is located in the sacral region. Tender areas are not associated with the deep seated pain, but, on the contrary, pressure tends rather to give relief. The crisis commonly arises during defecation, especially if accompanied by straining. On the other hand, the patient may be wakened from a sound sleep by the rapidly growing pain. Tenesmus is present, and the act of defecation, though at first it causes an exacerbation of the suffering, results in its cessation. In men the crisis may be accompanied by priapism. When the crisis has reached its zenith the onset of a general tremor or rigor, accompanied by the sensation of cold, is almost invariably followed by a rapid cessation of the pain. The pain may wax and wane, but the most severe attacks are often the shortest. Examination of the rectum during the attack has demonstrated in two cases the presence of a fine fibrillar tremor in the internal sphincter. Piles may be present and undoubtedly enter into the etiology. A severe type of rectal crisis was recently observed after colostomy in a case of inoperable cancer of the rectum. The lesion is a neurosis. In no case examined during the pain has the rectum been found quite empty, and constipation of a minor degree has been the rule. The treatment MacLennan has found most efficacious has been the inhalation of a dozen drops of chloroform placed on a handkerchief.

19. Treatment of Chest Wounds.—The chief practical points emphasized by Elliott are the following: A sterile hemothorax of moderate size, that is, of about 30 ounces, will recover as rapidly by natural absorption as by aspiration. The retention of foreign bodies in the chest in aseptic cases does not appear to exert any crippling effect for military service, but more accurate information is urgently needed on this point. Cases of infected hemothorax that have been drained in France and the patients transferred to the united kingdom, generally recover rapidly and completely. None die and subsequent operations are rarely needed. More than one-half of these empyema patients can be returned to duty. The late mortality from chest wounds is practically nothing in England, and it is only 5 per cent. on the lines of communication in France; but in the area of the armies it is higher than was at first supposed. About 10 or 15 per cent. may die in medical units at an early date from the severity of the injury and about 10 per cent. may die later at the casualty clearing stations from complicating sepsis. Among those casualties in which sepsis is developed within the chest the mortality is very high, rising to nearly 50 per cent. under the present system of treatment by rib resection and drainage. The old conservative routine of surgical nonintervention, except by late drainage, finds its justification only in the satisfactory recovery of those cases of gunshot wound of the chest which remain noninfected, that is, about 75 per cent. The high mortality in those patients who develop sepsis demands a wider practice of the new prophylactic method of cleansing operation performed at an early hour on certain carefully chosen groups of patients.

21. Trench Fever Associated with Hemogregarine.—The presence of a small hemogregarine, resembling in many respects the *Hemogregarina gracilis* found by Wenyon in a lizard host, has been noted by Dimond in the venous blood, the blood from the liver, spleen and lung punctures in twelve cases of trench fever. The fact that this protozoon of trench fever is a hemogregarine suggests the extreme probability that the *Pediculus corporis*, or what is even more likely, that a louse allied to the *Hematopinus stephensi* and parasitic on the Indian field rat, is the carrier of the protozoon. The presence of such large numbers of rats in the trenches, which come into close association with the troops seems to favor this conclusion. An effort is being made to trace out the cycle of sporogony in the stomach cells of the different types of lice commonly present in the underclothing of soldiers.

37. The Development of War Surgery.—Helme traces the history of the care of the wounded in war from Paré in the sixteenth century to Carrel in the twentieth. His quotation from Paré's book, published in 1545, reads as if it might have been written last week: "When I hear people speak of the weapons and war machines that used to be used in battles and in taking towns, they seem like children's toys in comparison to those that are being used today, which surpass in size and cruelty all that one could imagine of the most cruel." Mines, counter mines and grenades were already in use then, and wounds were dressed with boiling oil. Paré, the young barber-surgeon, used cool turpentined oil instead of boiling oil, in the numerous campaigns which he accompanied. Vesalius was about the same age at the same time and served in the enemy army. Each at the age of 28 published an epoch-making work, Vesalius breathing new life into anatomy and Paré creating surgical anatomy and introducing the ligation of vessels to arrest hemorrhage after an amputation. Before him, the bleeding vessels had been seared with a hot iron. Without any knowledge of the principles of antisepsis, he applied antisepsis in treatment of wounds, and his mixture of brandy, salt and water is not unlike the hypertonic solution which some advocate now for dressing wounds. Paré lived to be 80, serving four kings and tending thousands of soldiers in more than 100 battles. His work was translated into four other languages but, notwithstanding this, his influence on military surgery nearly all died with him. Only one principle survived, namely, the importance of avoiding delay before the wounded get surgical care. Larrey and Percy insisted on this principle in Napoleon's campaigns and preached "Operate quickly, operate thoroughly, and watch over the general condition as well as the local." The next great advance, Helme declares, was when Carrel showed how to ward off secondary infection and suture the wound early. He adds: "Carrel seems to have inherited in his fingers the delicate touch of his forebears, silk weavers of Lyons. After four years of intern service at Lyons and a term as prosector of anatomy, he spent several years at Chicago and then entered the Rockefeller Institute at New York where his leading idea—to perfect the surgery of the lungs—drew him on through the various phases of suturing of blood vessels, and means to stimulate healing, to his final successful technic, the secondary suture, which Professor Depage regards as the greatest discovery that has been made in surgery since Lister."

38. Epinephrin in Addison's Disease.—The case of Addison's disease described by Nolf and Fredericq is exceptional only in the extreme tolerance of the patient for epinephrin. The man of 38 with grave symptoms of suprarenal insufficiency was given 10.5 mg. epinephrin in four and a half hours; this included 2 mg. subcutaneously and 8.5 mg. intravenously. No sugar appeared in the urine and the blood pressure was not brought up quite to the normal figure even with this. The following days 6 and 4 mg. were given. There were no signs of intolerance at any time, even though to attain the desired therapeutic result these large doses were found necessary. The case teaches that we need not shrink from large doses of epinephrin in emergencies, as with acute suprarenal insufficiency under chloroform, or with gaseous gangrene or other hypotony of infectious origin. By watching over the blood pressure as the epinephrin is being taken, we can continue it and push it until the arterial pressure is brought up to a point where the functioning of the organs is possible once more.

39. Suprarenal Functioning During Acute Infections.—Goormaghtigh has been systematically investigating what occurs in the suprarenals under the influence of a general infection, before actual pathologic changes become installed. He examined seventy suprarenal capsules taken from the cadaver from fifteen to sixty minutes after death. This research demonstrated among other things that the suprarenals show macroscopic changes during the course of infectious processes complicating war wounds, more than any other organ in the body. The suprarenals become turgid, the surface grows redder, a bright red or a brownish or sepia red, while the organ increases in weight. From the very incipiency of the infection, the cortex pours out into the blood stream its reserve of cholesterol and proceeds to secrete more. In grave infections, terminating fatally in two or three days, all the reserves are exhausted. The secretion of new lipoids is activated. With infectious processes running an average of ten or twenty days, the suprarenals develop pathologic lesions, the most important of which seems to be the atrophy of the fasciculated zone. The glomerular zone seems to reenforce or substitute the functioning of this zone. Its task seems to be the collection from the blood of the materials necessary for the production of cholesterol. The other zones show signs of secretory hyperactivity. In infectious processes of slow development, the parenchyma of the gland becomes hypertrophied. The data presented apparently demonstrate a close analogy between the mechanism of the secretory processes in the suprarenals, corpora lutea, and the interstitial gland of the ovaries. The epinephrin-secreting medullary substance of the suprarenals is stimulated to enhanced secretion by the infection. The morphologic evidence of this hyperactivity is the pronounced differentiation of its constituent elements. In some cases this excessive activity completely exhausts this portion of the gland. In conclusion he reports that injection of epinephrin in the course of infections notably augments the activity of the medullary parenchyma of the gland. Three colored plates illustrate the phases which he describes.

40. **Relapsing Fever in East Africa.**—De Ruddere describes the clinical picture and the complications of relapsing fever as it appeared among the Belgian troops on their victorious march through German East Africa. It affected black and white troops alike. The ticks that transmit this disease are rare in the Belgian Congo but are extremely numerous in German East Africa, especially along the caravan routes. The disease is easily recognized by the frontal headache and pains in the bloodshot eyes. The spirilla are found in the blood during the febrile attack but not at other times. Salvarsan and its substitutes did not seem to have any curative action except at the first attack, but they materially relieved the pain and discomfort at each relapse. The duration and frequency of the attacks did not seem to be modified by them in the least. Iridocyclitis is a comparatively common complication, but this yielded to salvarsan or atoxyl in his experience. One man succumbed to complicating epistaxis, and in most of the severe cases the heart muscle was modified, the heart sounds duller and the pulse small and fast during and between the relapses. There may be ten or fifteen relapses of tick fever, and the men are sick with it for a total of rarely less than three months.

43. **Flies and Colored Lights.**—From the research by Galaine and Houlbert it seems evident that flies are able to see only white light. All rays outside of the range from green to orange fail to act on their eyes, and are perceived as darkness. In a room lighted through light blue glass the flies behaved as in the dark. Flies avoid rooms lighted through stained glass as if the rooms were dark.

44. **Preservatives in Foods.**—Satre remarks that the substances added to foods to prevent fermentation before they are eaten, prevent it also after they are eaten, so that the food is unable to be subjected to the normal digestive changes in the alimentary tract. The person thus suffers from defective digestion, while the liver and kidneys may be gradually affected by the minute doses of the preservative. The diagnosis is extremely difficult unless a whole group of persons eating the same food develop parallel dyspepsia, etc. Differential diagnosis may be difficult, even with such an easily suspected drug as arsenic ingested in minute amounts over long periods. The new-born, the elderly, and pregnant women are particularly sensitive. The infant gets salicylic acid in its breast milk if the mother is getting salicylic acid as a preservative in some article of food. If brought up on the bottle, its digestive functioning may be upset by the preservatives added to the cow's milk, or sodium bicarbonate or other substance used in cleaning the bottles. In the elderly, as the kidneys grow less permeable, the preservatives ingested in food are retained and pile up in the body. The kidney is also less permeable in the pregnant woman, and retained accumulating antiseptics have a directly injurious action on both herself and the fetus. Satre adds that as all questions connected with food are particularly grave now and pressing for solution, legislation in behalf of pure food, free from adulterations and preservatives, is of paramount importance now.

48. **Silent Peritonitis and Sudden Death.**—Minet reports three cases of sudden death in supposedly quite healthy soldiers. Death occurred in bed at night, and in each case necropsy revealed acute peritonitis, the sudden death being the first appreciable manifestation. One of the men had been kicked in the abdomen four days before and had fainted at the time, but then had apparently felt no further disturbance. Death came with absolute suddenness in each case.

54. **Hot Foods as Factor in Dyspepsia.**—Manquat relates various experiences which converted him to the opinion that in a very large proportion of cases dyspepsia and aerophagia are brought on and maintained by the habit of taking beverages and food too hot for the tissues to bear without injury. This is particularly the case with hot soups, tea, etc., taken on an empty stomach. The hot fluid passes so rapidly through the mouth that the buccal mucosa is not injured. When the hot drink is taken at the close of a meal, the injury is comparatively slight as the stomach walls are protected by other food. The thermometer will show temperatures of 60 or even 68 C. (140 or 154 F.) in soups and other dishes currently taken, and even higher than this in a baked potato. He found that those dyspeptics accustomed to hot beverages and hot soups usually had long, narrow and sagging stomachs. The stomach is tender under pressure and spontaneously painful at a variable period during digestion. Hypersecretion with varying acidity and constipation are the rule—all indicating a tendency to chronic gastritis. The action of ptyalin on starch becomes reduced at temperatures over 45 C. (113 F.) and pepsin may have a similar temperature range of action. The hand cannot be held in water at 45 C. (113 F.) without modifications in the respiration and the general circulation. These modifications must certainly be more profound when the extensive and delicate mucosa of the stomach is exposed to such high temperatures. In practice, when Manquat has been able to overcome the habit of hot drinks and foods, the dyspepsia improved notably. The symptoms from stagnation in the stomach and the aerophagia were the first to show the benefit. When heat is indicated for the stomach, he adds in conclusion, "apply it to the outside."

55. **The Antirat Campaign.**—Calmette relates that the *Mus rattus* has been known from the earliest historical times, but that the sewer rat was not known in Europe until 1727 when, owing to famine and extensive earthquakes in India, large bodies of sewer rats migrated westward and overran western Europe in a few years. By the end of the eighteenth century public rat-hunts were common; in one month 16,000 rats were killed in one building in France. Calmette reviews the history of the rat further, and shows that it is often responsible for transmission of trichinosis as well as of the plague. Remlinger has also proved the transmission of rabies from dog or cat to man by the bite of rats. He has reported the case of a girl at Smyrna who developed rabies after she had been bitten in the finger by a mouse that had attacked her, in her cellar, without the slightest provocation. Calmette describes the measures adopted in various countries to repress rats, saying that, left unmolested, one couple theoretically would breed 500,000 descendants in two years. Even if only a tenth survive, they form a formidable army. The system of bounties seems to work well, he says. In Stockholm 600,000 rats have been killed. At Odessa 500,000 roubles were appropriated for the purpose, and in the Japanese cities a bounty of 2 or 3 cents is paid. In France, the Danysz virus has been used on a large scale against destructive field mice, but it does not act so well on rats. Numbers have been killed with it but others escape. In the Antilles the mongoos, a weasel-like animal domesticated in India, was introduced to exterminate rats, which it does most effectually. But as it attacks also poultry, etc., its depredations were found worse than those of the rats. Calmette thinks that nonvenomous serpents would be better, such as the boa, which is a great consumer of rats while harmless for man. He adds that in 1909 the British parliament voted measures to promote and regulate the destruction of rats, and he pleads that the French parliament should imitate this example. The profession must educate public opinion to realize the enormity of the economic waste from the depredations of rats, and the dangers to which they expose the land from the murderous epidemics which they transmit.

62 *With Active Pulmonary Tuberculosis the Sputum May Contain Tubercle Bacilli from the First. C. Richet, Jr.—p. 508.

56. **The Fight Against Tuberculosis.**—Danysz explains the mechanism of infection by the tubercle bacilli as it differs from other infections. He shows how the special phase of production of antibodies which, in diphtheria, corresponds to immunization and the cure of the disease, in tuberculosis corresponds to the beginning of the pathologic state. In diphtheria it is the excess of toxins, in tuberculosis, the excess of antibodies within the cells which determines the pathologic moment and the lesions. He presents evidence further demonstrating that a certain relative immunity can be realized by bacteriovaccination. This, in connection with the spontaneous cures in certain cases, suggests that it may yet be possible to cure the disease with a combination of vaccination and chemotherapy. But scattered experiences and experiments do not afford an adequate basis for determining the best technic for both. This is a task too vast to be left to isolated establishments. To date, the hospitals, the sanatoriums have not been able to keep the tuberculous long enough and control the results with uniform methods. To realize appreciable progress, experimental and clinical experts must be grouped in establishments for study and cure of tuberculosis, the whole work systematized and endowed, so that every discovery, old or new, can be given a thorough test for its clinical value, under the best conditions for control. These studies will be necessarily long and expensive, but they will prove less expensive in the long run than the present haphazard methods in scattered clinics, etc., without any general direction. We know now that it is possible to render the organism more resistant to contagion, and the task before us is to utilize better the clinical and experimental data already acquired, and to organize new research to clear up certain still obscure points. The services of bacteriologists, chemists, physicians and veterinarians should be organized and correlated, carrying on parallel the study of tuberculosis in both man and cattle.

58. **Immediate Extraction of Projectiles.**—Fiolle follows the path of the projectile in seeking for it, and says that nine times out of ten, it is thus possible to find and remove the missile. He strives to open up and clear out the path down to the projectile without touching it with the fingers. As the path of the projectile has to be cleared out any way, he thinks this is better than cutting down on the projectile where it is shown by the roentgen rays. Béclère advocates the latter. With a little experience, roentgenography can be dispensed with in these immediate operations, with the passage-way of the bullet still gaping or easily permeable.

59. **American Medical Pioneers in Hygiene.**—Among the names mentioned in Matignon's historical sketch of American pioneer work in medical hygiene are besides Gorgas, Reed and Lazear, Capt. E. B. Vedder of beriberi fame, Major F. F. Russell of the army antityphoid vaccination, Gentry and Ferenbaugh who found Malta fever in Texas goats, and Major Hoff and Capt. B. K. Ashford who stamped out smallpox and ankylostomiasis in Porto Rico.

60. **Nerve Blocking in Treatment of Causalgia.**—Pitres and Marchand report that Sicard's method of injecting diluted alcohol into the trunk nerve has put an end to the distressing cases of intense pain, or causalgia, following a war wound. Before this method was introduced, they had numbers of wounded suffering tortures from this cause which they were unable to relieve by any measures. The pains subsided at once on blocking the nerve with alcohol, injecting 60 per cent. alcohol into the nerve above the lesion in the thirty patients given this treatment. Three cases are described in detail to demonstrate that this nerve blocking does not aggravate preexisting motor paralysis or bring on new. On the contrary, when the pain was arrested by the alcohol, certain other disturbances disappeared with it, especially the co-organic paralysis, the nature of which is still a mystery. The causalgia in the first case had persisted for a year, not modified by an operation to free the nerve embedded in cicatricial tissue. The second patient had been wounded in the thigh, and the causalgia accompanied paresis in the domain of the femoral nerve. The femoral nerve was opened up under chloroform and 4 c.c. of 60 per cent. alcohol injected. The pains disappeared at once, and also the paresis but more gradually. Alcohol at 60 per cent. interrupts conduction of sensation but apparently does not modify conduction of motor impulses. Before the nerve blocking there was partial reaction of degeneration, but this gradually became total notwithstanding the conservation of volitional contractility in the muscles involved. In the third case the pains were in the palm although the wound was on the arm. The alcohol was injected in the wrist, but this induced merely a very brief and fleeting relief of the pain. This experience sustains Sicard's directions that the nerve has to be blocked above the lesion to be effectual.

61. **Diagnosis of Sciatica.**—Roussy gives some illustrations showing the attitudes inevitably assumed with true sciatica in doing certain exercises. For example, in trying to bend over and touch the floor, the knees stiff, the knee on the side of the sciatica is necessarily bent, or else the foot kicks out behind. When the patient sits on the floor with legs straight out, the knee on that side is always bent a little, and it cannot be fully extended. Pressure on the knee to extend the limb straight causes a sharp pain in the sphere of the sciatic nerve. Another test is the pain felt when the trunk is bent forward. The trunk has to be kept within a given angle to avoid increasing the pain of the sciatica. This unilateral

renals show macroscopic changes during the course of infectious processes complicating war wounds, more than any other organ in the body. The suprarenals become turgid, the surface grows redder, a bright red or a brownish or sepia red, while the organ increases in weight. From the very incipiency of the infection, the cortex pours out into the blood stream its reserve of cholesterol and proceeds to secrete more. In grave infections, terminating fatally in two or three days, all the reserves are exhausted. The secretion of new lipoids is activated. With infectious processes running an average of ten or twenty days, the suprarenals develop pathologic lesions, the most important of which seems to be the atrophy of the fasciculated zone. The glomerular zone seems to reenforce or substitute the functioning of this zone. Its task seems to be the collection from the blood of the materials necessary for the production of cholesterol. The other zones show signs of secretory hyperactivity. In infectious processes of slow development, the parenchyma of the gland becomes hypertrophied. The data presented apparently demonstrate a close analogy between the mechanism of the secretory processes in the suprarenals, corpora lutea, and the interstitial gland of the ovaries. The epinephrin-secreting medullary substance of the suprarenals is stimulated to enhanced secretion by the infection. The morphologic evidence of this hyperactivity is the pronounced differentiation of its constituent elements. In some cases this excessive activity completely exhausts this portion of the gland. In conclusion he reports that injection of epinephrin in the course of infections notably augments the activity of the medullary parenchyma of the gland. Three colored plates illustrate the phases which he describes.

40. **Relapsing Fever in East Africa.**—De Ruddere describes the clinical picture and the complications of relapsing fever as it appeared among the Belgian troops on their victorious march through German East Africa. It affected black and white troops alike. The ticks that transmit this disease are rare in the Belgian Congo but are extremely numerous in German East Africa, especially along the caravan routes. The disease is easily recognized by the frontal headache and pains in the bloodshot eyes. The spirilla are found in the blood during the febrile attack but not at other times. Salvarsan and its substitutes did not seem to have any curative action except at the first attack, but they materially relieved the pain and discomfort at each relapse. The duration and frequency of the attacks did not seem to be modified by them in the least. Iridocyclitis is a comparatively common complication, but this yielded to salvarsan or atoxyl in his experience. One man sucumbed to complicating epistaxis, and in most of the severe cases the heart muscle was modified, the heart sounds duller and the pulse small and fast during and between the relapses. There may be ten or fifteen relapses of tick fever, and the men are sick with it for a total of rarely less than three months.

43. **Flies and Colored Lights.**—From the research by Galaine and Houlbert it seems evident that flies are able to see only white light. All rays outside of the range from green to orange fail to act on their eyes, and are perceived as darkness. In a room lighted through light blue glass the flies behaved as in the dark. Flies avoid rooms lighted through stained glass as if the rooms were dark.

44. **Preservatives in Foods.**—Satre remarks that the substances added to foods to prevent fermentation before they are eaten, prevent it also after they are eaten, so that the food is unable to be subjected to the normal digestive changes in the alimentary tract. The person thus suffers from defective digestion, while the liver and kidneys may be gradually affected by the minute doses of the preservative. The diagnosis is extremely difficult unless a whole group of persons eating the same food develop parallel dyspepsia, etc. Differential diagnosis may be difficult, even with such an easily suspected drug as arsenic ingested in minute amounts over long periods. The new-born, the elderly, and pregnant women are particularly sensitive. The infant gets salicylic acid in its breast milk if the mother is getting salicylic acid as a preservative in some article of food. If brought up on the bottle, its digestive functioning may be upset by the preservatives added to the cow's milk, or sodium bicarbonate or other substance used in cleaning the bottles. In the elderly, as the kidneys grow less permeable, the preservatives ingested in food are retained and pile up in the body. The kidney is also less permeable in the pregnant woman, and retained accumulating antiseptics have a directly injurious action on both herself and the fetus. Satre adds that as all questions connected with food are particularly grave now and pressing for solution, legislation in behalf of pure food, free from adulterations and preservatives, is of paramount importance now.

48. **Silent Peritonitis and Sudden Death.**—Minet reports three cases of sudden death in supposedly quite healthy soldiers. Death occurred in bed at night, and in each case necropsy revealed acute peritonitis, the sudden death being the first appreciable manifestation. One of the men had been kicked in the abdomen four days before and had fainted at the time, but then had apparently felt no further disturbance. Death came with absolute suddenness in each case.

54. **Hot Foods as Factor in Dyspepsia.**—Manquat relates various experiences which converted him to the opinion that in a very large proportion of cases dyspepsia and aerophagia are brought on and maintained by the habit of taking beverages and food too hot for the tissues to bear without injury. This is particularly the case with hot soups, tea, etc., taken on an empty stomach. The hot fluid passes so rapidly through the mouth that the buccal mucosa is not injured. When the hot drink is taken at the close of a meal, the injury is comparatively slight as the stomach walls are protected by other food. The thermometer will show temperatures of 60 or even 68 C. (140 or 154 F.) in soups and other dishes currently taken, and even higher than this in a baked potato. He found that those dyspeptics accustomed to hot beverages and hot soups usually had long, narrow and sagging stomachs. The stomach is tender under pressure and spontaneously painful at a variable period during digestion. Hypersecretion with varying acidity and constipation are the rule—all indicating a tendency to chronic gastritis. The action of ptyalin on starch becomes reduced at temperatures over 45 C. (113 F.) and pepsin may have a similar temperature range of action. The hand cannot be held in water at 45 C. (113 F.) without modifications in the respiration and the general circulation. These modifications must certainly be more profound when the extensive and delicate mucosa of the stomach is exposed to such high temperatures. In practice, when Manquat has been able to overcome the habit of hot drinks and foods, the dyspepsia improved notably. The symptoms from stagnation in the stomach and the aerophagia were the first to show the benefit. When heat is indicated for the stomach, he adds in conclusion, "apply it to the outside."

the usual throat localization. In the two other cases of ocular complications there was merely paralysis of the oculomotor muscles, and this did not seem to be influenced by the intensive antitoxin treatment applied, both children being left with squint. The prognosis with oculomotor paralysis should be reserved, as one never knows whether the oculomotor nerve center has been destroyed by the diphtheria toxin or has been merely transiently injured.

74 *Effect of Cholesterol in Culture Medium on Development of Germs. L. Manfredi.—p. 849.
75 History of Acromegaly. (Rivendicazioni italiche.) A. Ferrannini. —p. 857.

74. Cholesterol in Culture Mediums.—Manfredi reports that addition of 0.5 per thousand cholesterol to the ordinary culture mediums did not seem to affect the development of typhoid and allied bacilli. A larger proportion checked their growth even when the content was less than the cholesterol content liable to be found in the blood in corresponding cases of these diseases. The colon bacillus and the streptococcus of erysipelas and puerperal fever were checked only with proportions over 1 per thousand, and the staphylococcus, diphtheria and cholera germs only with 2 per thousand.

78 Entameba Found in Snake. (Entameba serpentis, n. sp.) A. M. de Cunha and O. da Fonseca.—p. 279.

76. Tuberculosis at Rio de Janeiro.—Barbosa remarks that the mortality from tuberculosis at Rio is higher than in the thirty other large cities of the world. It is surpassed only by that of Caracas in Venezuela and Callao in Peru while the climatic and sanitary conditions in these latter cities are far below the level of the Rio of today. The tuberculosis mortality has declined everywhere, and in Rio it dropped from about 12 per thousand inhabitants in 1863 to about 4 since 1903, the variable range since being from 4.61 to 3.83 per thousand inhabitants. Barbosa pleads to have tuberculosis and prophylactic measures against it included in the routine work of the national public health department, with a special chief for the tuberculosis work. He enumerates the measures found useful elsewhere, and urges their adoption, with penalties for promiscuous spitting. He emphasizes that tuberculosis is an epidemic disease and should be handled like all epidemic diseases. The fact that it is chronic instead of an acute epidemic does not alter the threefold principles on which every epidemic should be combated, notification, isolation and sterilization. He insists on compulsory notification but does not approve of relying on terminal disinfection. Yellow fever is almost the only disease with which terminal disinfection is of vital importance, as this kills the infected mosquitoes. Tubercle bacilli, on the other hand, rapidly succumb to air, light and drying. Rio is particularly fortunate in its housing conditions, in comparison to other large cities. There is no overcrowding; the houses have light, air and space in abundance, and there are scarcely any tenements. The high tuberculosis morbidity is due to the unrestricted dissemination of the germs and the low resisting powers of the populace which consists in large proportions of half-breeds who are extraordinarily susceptible to tuberculosis. The excellent housing conditions, the universally recognized authority of the public health service, and the docility of the people render very promising a well planned campaign against tuberculosis.

77. Hookworm in the Brazilian Navy.—Carrero protests against recent rumors in regard to the prevalence of disease in the navy, citing his own experience as fleet surgeon for the last six years. Salt water is peculiarly unfavorable for the hookworm and its transmission on ships is exceptional. Among the 6,511 marines and crews stationed at Rio in 1916, there were 214 who were given treatment for hookworm, but he doubts whether in any instance it had been acquired after entering the navy service. Only one of the thirteen patients with malarial polyneuritis had hookworm, and none of the five with beriberi. There was no death attributable to hookworm in the navy. The dispensary for hookworm patients opened in 1915 in the Marine Hospital has had to be closed for lack of patients.

82. The Balantidium Coli in Argentina.—Parodi and his co-workers report in detail three cases of balantidiosis in persons who had always or for twenty years lived in Argentina. The case histories and the illustrations testify that the *Balantidium coli* is prevalent in Argentina and is liable to induce the same pathologic states as it induces in other countries, and it may breed healthy carriers. Systematic examination of the stools in diarrheas and dysenteries should be the routine practice. The first known case in Argentina was published only last year. Parodi's first case was in a boy of 8. He was apparently healthy, but the stools contained not only the *Balantidium coli* but also the necator, hymenolepis and trichocephalus. Repeated examination showed that the balantidium disappeared from the stools in the course of two weeks. Possibly the exclusive milk and vegetable diet may have contributed to its disappearance. One other child in the family was said to have been having diarrhea for over a year. In the two other cases reported the balantidiosis was very severe; the adult recovered under suppression of meat and treatment with acid enemas and intravenous injections of 0.01 gm. of mercuric cyanid. No specimens of the balantidium could be discovered after the ninth day. The other patient, a boy of 9, died. The parasites had burrowed into the mucosa and induced ulceration at various points. Numerous young forms of the parasite were found close to the edges of the ulcerations, showing that it finds in them specially favorable conditions for reproduction. In each of the three cases the patients had come to the hospital for another cause, treatment of hernia or pleurisy, and the discovery of the parasite was casual. In the first it caused no symptoms; in the second case, periods of tenacious diarrhea alternated with periods of good health. In the third, the toxic necrosis of the bowel proved promptly fatal.

86. Ichthyolized Petrolatum for Burns.—Suarez has been using for ten years a 10 or 15 per cent. ichthyolized petrolatum in treatment of burns, and he here expatiates on its analgesic and healing power and the fact that with it the dressings do not stick to the tissues.

87. Cheese in Infant Feeding.—Menshikoff describes striking results in infant feeding with curds, cheese curds (*tvorog*), after serious disturbance from too exclusive carbohydrate and salt-containing foods (soups and broths). He gives the full details of seven cases of this type. One child of 19 months, for example, weaned at the twelfth month, had signs of rachitis, with pale, doughy skin, weak pulse, subfebrile temperature, languor and apathy, and cold hands and feet, with diarrheic stools, with mucus content, averaging ten passages a day. There was no albuminuria. Pressure on the ankles left a deep pit. All other feeding was stopped and nothing allowed but rice water with five tablespoonfuls of cheese to the liter as the daily amount. After two days the stools lost their diarrheic character and there were only two passages a day. Then a quarter of the fluid was given in the form of cow's milk, and at once the diarrhea returned, four watery passages a day. The milk was stopped after two days, and the diarrhea subsided. The general condition had much improved by this time, the hands and feet keeping warm. The edema then was gradually thrown off, the weight dropping, and by the end of the week there was no further evidence of the dropsical tendency. Then very slowly and gradually the ordinary diet was resumed, adding to the rice water and cheese small amounts of acorn coffee made with milk, yolk of egg, bread, etc., so that by the end of the month the weight had increased from the original 7,600 to 7,700 gm. notwithstanding the intervening loss of 1,000 gm. as the dropsy was thrown off. The case illustrates the extreme caution necessary in resuming milk, after conditions have been righted under the cheese.

The work issues from the clinic for children's diseases at the University of Kazan, and Menshikoff theorizes to explain the mechanism of this benefit from the cheese with such severe upset of metabolism. He adds that the absence of the salts in the whey of milk, and of carbohydrates, on the one hand, and the predominance of albumin make this method of feeding especially advantageous when there is diarrhea from excessive fermentations in the bowels. In acute upsets of the salt metabolism, with edema in the subcutaneous tissues, any food containing salts and carbohydrates is directly contraindicated. Under the restriction to cheese the dropsy promptly disappears, the tolerance for food is increased, and the normal functioning of the tissues is restored. After the edema has disappeared, food containing salts and carbohydrates can be resumed without bringing back the previous disturbances. The weight drops as the edema subsides, but this loss in weight is not accompanied with collapse and is highly desirable. As there is no further intake of salts on the cheese diet, the source of the edema is removed and there is no return of the edema on resumption of the ordinary diet. One of another group of typical cases of which the details are given was that of a child of 6 months with pronounced atrophy and other indications of nutritional disturbance from too exclusive carbohydrate feeding. It had been taken from the breast four months before and had been fed on milk diluted 2:1, milk gruel and biscuit. It weighed only 4,690 gm. and had long been having ten diarrheic green passages a day, with much gas, and the child was very restless. It was then put on milk diluted with gruel, 1:2, with 4 per cent. sugar. The diarrheic stools continued, and the child was losing rapidly in weight. The next day it was given rice water to 900 c.c. a day, with one dessertspoonful cheese to each 200 gm. By the next day the stools were compact and there was no further loss of weight. In four days the weight had risen to 4,620 gm., and the child seemed quiet and to feel well. Then the diet was changed to 300 gm. milk; 600 gm. of the rice water; six dessertspoonfuls cheese, and 3 per cent. sugar. The stools continued normal, and the weight in nine days had risen to 4,900 gm.

An older child, 2½ years old, had been eating at the regular table but was debilitated by diarrhea for two months and nervous, with attacks of convulsions, and chilliness. After failure of the ordinary measures, he restricted the diet to the rice water with a tablespoonful cheese to each 200 gm., allowing the child as much of this as it cared to take; it took 1,250 gm. per day. By the tenth day the bowel functioning seemed to be normal, during the last week the diet had gradually been enlarged to include bouillon, chops and baked apples. There were no further convulsions and the child seemed in excellent health, having regained nearly its former weight by the end of the second week. In conclusion he expatiates on the advantages of cheese as inexpensive and readily accessible to all, and not requiring clinical supervision. He has repeatedly ordered it for dispensary children. He warns, however, that when the debility from the drain of the diarrhea has reached an extreme degree, so that the child would be unable to stand deprivation of salt from the food, this method of feeding is contraindicated.

96. **War Fracture of the Femur.**—Metz relates his experiences in this line when with the Netherlands ambulance in Silesia where he had seventy cases in his charge. He applied extension by driving a nail into the femur or tibia in thirty-five cases, and never witnessed anything suggesting infection entering through the nail hole.

100. **Segmental Sensory Innervation of the Hind Leg of the Cat.**—De Boer is instructor at the University of Amsterdam and first assistant at the physiologic laboratory. He has previously published research on the segmental innervation from the thoracal portion of the spinal cord. He here reports similar research on the lumbar and sacral cord, defining the segments in the hind leg of cats, and reproducing the dermatomeres in drawings. He never found them alike in any two cats, so he speaks only of averages, not normal standards.

101. **Depressions in the Skull as Sign of Rachitis.**—Quant called attention some time ago to a transverse and a vertical depression in the occipital bone which he found in 60 per cent. of the cases of rachitis examined. These depressions seem to develop more readily with skulls inclined to be long rather than broad. Lying on the side of the head during early infancy seems to increase the chance for this T-shaped depression. It was found in the mild as well as in the severe cases of rachitis, and it may be the first to appear of the signs of rachitis and the last to disappear. This may aid the practitioner in the diagnosis of rachitis. Above and on both sides of the depressions, the skull bone has the normal curve, but, owing to the depressions, the bone looks as if it bulged abnormally on each side and above. This is the reason why this skull anomaly has been called tri-bounocephaly, the three-hill skull, from the Greek term *bounos*, "hill." To detect the depressions on the living child, the head is bent over backward to relax the muscles. The horizontal depression can be most easily determined; drawing the fingers down along the scalp, to the side of the median line, the fingers sink into the transverse depression. There can be no doubt about the gully, as he calls it, as it lies above the point of attachment of the muscles. The finding of the transverse depression is usually enough; the existence of the other may be surmised. In his experience they were always associated. His roentgenogram of one case shows distinctly the long and wide transverse depression and the perpendicular groove with the "three hills" to right, left and above the T. The findings were distinct in 60 per cent. of forty-five rachitic children examined and less distinct in an additional 18 per cent.

VOL. LXIX, No. 18 CHICAGO, ILLINOIS NOVEMBER 3, 1917

THE SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

RETROSPECT AND PROSPECT *

DWIGHT H. MURRAY, M.D.
SYRACUSE, N. Y.

The American Proctologic Society was formed in Columbus, Ohio, in 1899, with twelve charter members. It has maintained its position and regularity of meetings with success and benefit since that time. Prominent among the charter members will be found such names as Matthews, Tuttle, Pennington, Cooke, Adler, Beach, Evans and Earle. To this original coterie of men many honorable and conscientious workers have since been added.

The American Gastro-Enterological Association was formed about the same time. This association has maintained a regularity of meetings and position since the year 1897. Prominent among the founders were such men as Aaron of Detroit, Benedict of Buffalo, Einhorn of New York, Hemmeter of Baltimore and Stewart of Philadelphia. Dr. Stewart was elected first president, and Dr. Aaron was the first secretary, which office he held continuously for fourteen years. To these pioneers many have been added, so that this association is quite representative. Among these I gladly mention some of the ex-presidents and others of prominence well representing the type of men who now compose that organization: Stewart, Meltzer, Bettmann, Friedenwald, Cannon, Sawyer, Kauffmann, Stockton, Morgan, White, Jones, Lockwood, Bloodgood, Finney, Meyer and Bassler; and many others deserve to be mentioned.

Samuel J. Meltzer of New York was president in 1904 and 1905, and his two presidential addresses on the subjects, respectively, "Our Aims" and "The Men We Lost" were instrumental as introspective agents in building the society up to the splendid organization that it finally came to be. One of the best things that Dr. Meltzer ever did for the benefit of the association was to create a committee on admission whose duties consisted in investigating and scrutinizing the moral and scientific standing of each applicant.

As time went on, the course of events proved that societies of specialists, while pleasurable to their own members, did not offer much for the advance of their subjects to the rank and file of the profession. To meet as a small body, one specialist reading a paper to others, served a very minimum benefit, because, first, the good that such a society could bring about was limited, and secondly, it could not fulfil a service or play a large part in correcting the lack of knowledge in others owing to deficient experience, limited opportunities, and the lack of special courses of instruction in gastro-enterology and proctology in most of the medical colleges in this country.

The mutations of time have changed the status and practice of gastro-enterology and proctology from a condition of well-merited criticism to one of honor and distinction, and it is for this reason that the American Medical Association established a section recognizing these two fields of work. In its establishment there were only two dissenting votes, and we wish to extend our thanks to the House of Delegates of the American Medical Association for its considerate and complete action. It is now for us to justify their faith by showing superior quality of work in this section, which I am sure will be done. There have been pathfinders in the past, and we are the founders or establishers of the advancement today. I predict that this section will be second to none in point of importance and attendance, and that eventually it will be the second medical section in point of interest.

There is no one thing that at a stroke has done more to remove these fields from the hands of quacks, commercialists and the reproach of the past than the establishment of this section. Having been given the responsibility, and no responsibility comes without obligation, we accept both and intend to do our part, for we know that what we do will be broadly spread before the profession, and we are willing to be judged accordingly. We further recognize that all beginnings are difficult, and that the success of this section depends on our own exertions and the good will of all.

We hope that gastro-enterology and proctology will be especially taught in our medical schools, that the students of the future will at least have such fundamental knowledge of these fields that the public will be benefited thereby, and that when any member desires further knowledge, this section will be the annual mouthpiece to teach the things that should be known.

We hope our meetings will stimulate additional research, because there is much to be done. In the endeavor to be fair to both gastro-enterology and proctology, and considering our future section work as a whole, the following subjects are suggested for elucidation. There is much still to be learned about the effects of pyorrhea on the gastro-intestinal tract. Research work in connection with saliva has been neglected of late years. Should there not be a rearrangement of the classification of gastric conditions? What is the true etiology of gastroduodenal ulcer? Why is the stomach more often affected by cancer than any other internal organ? Do we know all we should about so-called precancerous lesions? Is the medical treatment of stomach and intestinal conditions known and

---

* Chairman's address, read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

undertaken by the rank and file of the profession as it should be?

There is much of gallbladder pathology yet to be learned. Intestinal stasis is still being debated, pro and con, both as to its etiology and as to the proper treatment. What about bacterial flora in connection with intestinal toxemia? What is the cause of many chronic colonic conditions, to which likewise may be added changes in the mucous membrane of the rectum? Is the treatment of hemorrhoids a medical or a surgical question, and to what extent? What is the best service we can render in the treatment of the colon and rectum? What are we doing with pruritus ani, vulvae and scroti? There are also the roentgenray and the laboratory sides; abdominal conditions accompanying diseases of other organs, and so on almost ad infinitum.

It seems to me that during our discussion of the symposiums much can be said that would be of great benefit to the military service and the life of the boys in the Army as to the care of their digestive and eliminative tracts. Advice along this line could come from no more competent body of medical men than are in this section of the American Medical Association, and I believe it would be pertinent, notwithstanding the fact that we shall have many good physicians as officers of the Army, and without doubt they would welcome such advice. Nothing could make for greater efficiency in our Army than the keeping of the gastroenterocolonic tract in a normal condition. Possibly the offering of such advice at the present time may be too late, but I would recommend the appointment of a committee of five to formulate rules for the care of the gastro-intestinal tract. Such committee should deal especially with nutrition and elimination, and submit its report to the general committee of national defense, if it is found that the medical advisory board would welcome such advice, with the recommendation that a copy be placed in the hands of every soldier or his medical officer.

We have much to do in the line of research work, as well as considerable work of instruction. While congratulating ourselves on the formation of this section, let us enter into its future with a spirit that will bring the greatest good to the greatest number.

Controlling Malaria.—In cooperation with the U. S. Public Health Service, under the general supervision of the late Dr. R. E. von Ezdorf and his assistants, an experiment was conducted by the International Health Board of the Rockefeller Foundation at Crossett, Arkansas, in the practical control of malaria. The experiment was based on mosquito control without major drainage operations. It consisted of draining and regrading of natural streams so as to secure rapid offflow, the filling of bottoms, the digging of ditches, the removal of accumulated vegetation and the systematic use of oil and other larva-killing substances. As an indication of the results of these experiments, during the last six months of 1915 there had been 2,100 malaria calls on physicians in Crossett; during the last six months of 1916, there were 310 calls. In October, 1915, there were 600 calls; in October, 1916, there were 46 calls. In December, 1915, there were 100 calls; in December, 1916, only 4 calls. In Lake Village, 103 homes on plantations in the vicinity of the town were selected and divided into four groups to which different methods of prevention were applied. In the first group, control was based on screening; in the second, on prophylactic doses of quinin; in the third, on a combination of the two measures; a fourth group was kept under observation as a negative control without the use of any measures. The experiment has been completed but the results have not yet been announced.

"TRUTH ABOUT INTRASPINAL INJECTIONS IN TREATMENT OF SYPHILIS OF NERVOUS SYSTEM"

A REPLY

JOHN A. FORDYCE, M.D.
Professor of Dermatology and Syphilology, Columbia University, College of Physicians and Surgeons
NEW YORK

An address by the chairman of the Section on Nervous and Mental Diseases, Dr. Bernard Sachs,[1] was read at the Sixty-Eighth Annual Session of the American Medical Association entitled "Truth About Intraspinal Injections in Treatment of Syphilis of the Nervous System."

If the statements contained in that article are accepted by the medical profession as a final and correct judgment of this new therapeutic procedure, an enormous amount of harm will result in that numerous victims of syphilis of the nervous system will be deprived of their only chance to regain health and economic efficiency. The attempt to discredit the value of serologic examination of the spinal fluid as a diagnostic procedure and guide to treatment should not be permitted to gain credence without a word of protest. In the address in question there are several statements that are entirely at variance with the experience of my colleagues and myself, who have employed the method over a period of years in the manner we consider technically correct. We have seen numerous patients, treated for months intensively by salvarsan given intravenously with little or no clinical improvement, entirely relieved of tabetic pains, crises, bladder symptoms and sexual impotence, and with a marked improvement in their ataxic gait after the institution of intraspinal treatment. The following clinical histories and serologic findings illustrate the contention that intraspinal treatment can and does accomplish much more than the intravenous method.

REPORT OF CASES

Case 1.—A man, aged 40, with tabes, who had had a chancre eight years previously, for one year had suffered from lancinating, neuralgic pains in the legs, girdle sensation, very marked ataxia, and inability to walk farther than a city block. He was intolerant to mercury, and numerous intravenous injections of salvarsan over a period of six months produced no effect whatever. His fluid findings after intravenous treatment were: cells, 46; globulin, + + + +; Wassermann test, + + + + to 0.2 c.c.; the blood was + + + +. He then received twenty intraspinal injections. The leg and girdle pains entirely disappeared; the bladder is normal, and the sexual power has improved. He has gained 50 pounds in weight, and is able to walk 4 or 5 miles without assistance or fatigue. For three years he has been back at his work. The serologic findings in the fluid and blood became negative after the sixteenth treatment, and have remained negative for two and a half years. The patient has had no clinical relapse.

Case 2.—A man, aged 43, with tabes, had had a chancre in 1899. For four years he had shooting pains in the upper part of the back and thighs, at times so severe that he was obliged to remain in bed for from one to three days. There were Argyll Robertson pupils; the knee and ankle jerks were absent; the reflexes of the upper extremity were sluggish, the right more so than the left; there was slight ataxia; the bladder was a little slow; there was an area of anesthesia over the left breast just below the nipple. The patient was nervous and irritable, and suffered from such profound mental depression that his business judgment and activity were markedly impaired. Before coming to New York he was intensively treated with salvarsan and mercury, with no abatement in the pains or other symptoms. The fluid findings when he first came under observation were: cells, 234; globulin, + + + +; Wassermann test, + + + + to 0.4 c.c.; colloidal gold test, 2332110000; serum, —. He received fourteen intravenous and fourteen intraspinal injections, which treatment has been followed by a complete disappearance of the pains, ataxia and bladder trouble. The patient's depression has entirely lifted, he has returned to his business with renewed interest and vigor, and he is able to carry through large enterprises with his former energy. He has gained 25 pounds in weight. His fluid findings have just become negative, eight months after the beginning of treatment.

---

[1] Sachs, Bernard: Truth About Intraspinal Injections in Treatment of Syphilis of Nervous System, The Journal A. M. A., Sept. 1, 1917, p. 681.

Case 3.—A man, aged 24, with tabes, had had a chancre six years before. For three years he had had attacks of severe shooting intermittent pains in the upper and the lower extremities and in the chest. The pupils were unequal, irregular and very sluggish to light; the upper reflexes were present and equal; the left patellar and ankle jerks were very weak. The patient's sexual power and bladder were not impaired. He had had twenty-two injections of salvarsan besides several years' treatment with mercurial inunctions and injections when he came under my care. At this time the blood was negative. A lumbar puncture revealed: cells, 34; globulin, +; Wassermann test, + + + + to 0.8 c.c.; colloidal gold test, 1123210000. After combined treatment of six intravenous and six intraspinal injections the fluid became negative. The pains for which the patient sought relief disappeared after the third intraspinal treatment.

Case 4.—A man, aged 40, with cerebrospinal syphilis, had had a chancre in September, 1915, followed by secondaries for which he received immediately ten injections of salvarsan at weekly intervals, reinforced and followed by weekly injections of mercury over a period of nine months. In December, 1916, when he was first seen, he complained of lancinating pains all over the body, and occipital headaches. The pupils were unequal and irregular, the left sluggish to light, the right reacting promptly. The biceps, triceps, and radial reflexes were slightly more active on the right side. The knee and Achilles jerks were equal and normally active. A lumbar puncture made, Dec. 15, 1916, revealed: cells, 10; globulin, +; Wassermann test, + + + + with 1 c.c. Twenty-three intravenous injections were followed by some amelioration in the pains and headaches, but no change in the fluid other than a negative cell count. Ten intraspinal treatments brought about a complete cessation of the symptoms and a normal fluid.

Case 5.—A man, aged 30, with cerebrospinal syphilis, had had a chancre in 1906. Six years before I saw him he had a left external strabismus and facial palsy. When first seen in January, 1916, he showed the residua of these paralyses. All the reflexes on the right side were more active than on the left; the pupils were unequal, irregular and fixed to light; the bladder and the sexual power were normal. The patient was suffering from headaches and severe pains in the lower extremities. The blood was + + + +; the spinal fluid showed 148 cells; globulin, + + + +; Wassermann test, + + + + to 0.8 c.c.; colloidal gold test, 1123310000. After twenty-one intravenous injections of salvarsan, besides weekly doses of mercury, the cells were reduced to 9 and the globulin to + +; the Wassermann test was unchanged; the headaches disappeared, but the leg pains remained. The patient was then placed on a course of intraspinal injections, of which fourteen were given along with fourteen more intravenous treatments. The biologic results have been completely negative for three months. The pains, which were such a refractory symptom, left the patient after the sixth intraspinal treatment, and have not recurred.

Case 6.—A woman, aged 38, with syphilitic meningitis, gave no history of syphilis. In September, 1915, she developed symptoms of meningitis with severe occipital headaches and epileptiform seizures. The blood was + + + +. She was treated intensively by her physician with salvarsan intravenously and mercury, but without amelioration in her condition. When she came under my care in March, 1916, the spinal fluid revealed: cells, 86; globulin, + +; Wassermann test, + + + + with 1.0 c.c.; colloidal gold test, 1123200000. At this time she was placed on the combined intravenous and intraspinal medication. To the first two treatments she reacted with a chill, rise of temperature, nausea and vomiting. The reactions, however, grew less after subsequent injections until she was able to take them without any aftereffect. Four months from the beginning of treatment, and after the fifth injection, the Wassermann test on the fluid was negative, the cells numbered 17, and the globulin was +. The patient received three more intraspinal injections, after which only a trace of globulin persisted. The headaches disappeared entirely after the second injection, she was able to resume her family and social activities, and her whole physical condition improved markedly; her weight, which had been down to 89 pounds, increased to 100 pounds. Slight epileptiform attacks recurred at rare intervals for eight months and then left her free. A lumbar puncture, made July 11, 1917, revealed: cells, 3; globulin, very faint trace; Wassermann test, negative; colloidal gold test, negative. The blood was negative. In all she had eight intravenous and eight intraspinal injections.

It does not require the experience of a trained neurologist to convince these patients that their condition has been changed from hopeless invalidism to comparative good health. The advocates of intraspinal therapy have never claimed for the method that it should be used to the exclusion of the intravenous method, nor have they claimed that the choroid plexus is impermeable in all cases, and that remedies introduced intravenously could not reach the cerebral or spinal tissues. On the contrary, it has been repeatedly stated that many cases of syphilis of the nervous system are favorably influenced or cured by this method. In support of this statement I have cited cases in which such results were obtained, and again to emphasize the fact record the following:

Case 7.—A man, aged 32, with tabes, had had the initial lesion fourteen years before. There had been tabetic symptoms for four years with lancinating pains, loss of coordination, most pronounced ataxia, impotence, and impairment of rectal and vesical control. There were Argyll Robertson pupils; the deep reflexes were absent. The serum was + + + +. The spinal fluid, Feb. 10, 1912, revealed: cells, 34; globulin, + +; Wassermann test + + + + to 0.2 c.c. The treatment consisted of fifteen salvarsan injections intravenously, and inunctions and injections of mercuric chlorid. The patient has been free from pain for three years. His bladder is still a little slow, and his sexual power has not returned. His ataxia, which was such a prominent symptom that he was hardly able to walk across the room, is now scarcely perceptible, and he frequently walks from 5 to 10 miles a day. The serologic findings, Aug. 30, 1917, were: serum, —; spinal fluid: cells, 2; globulin, —; Wassermann test, — with 2 c.c.; colloidal gold test, negative. This patient, who on account of his physical disability in 1912 was obliged to resign his position and was unable to work for two years, has during the past two years resumed his occupation, which he follows with zest and enjoyment.

Case 8.—A man, aged 43, with tabes, had had a chancre twenty years before. Two years before he had double vision. When seen in January, 1911, his pupils were slightly irregular, but reacted fairly well to light and accommodation. The knee and ankle jerks were absent; the reflexes of the upper extremity were diminished, the left more so than the right. There was slight hypesthesia to pain and touch over the lower limbs. He was exceedingly nervous, and complained bitterly of his neuralgic pains. The serum was + + + +. The first lumbar puncture was made in November, 1912, and revealed 14 cells; globulin, + +; Wassermann test, + + + + with 1 c.c. The serum was negative. Treatment consisted of ten intravenous injections of salvarsan and several courses of mercury. There was a complete regression of the pains, which had been such a pronounced symptom, and of his nervousness and irritability. A second puncture made *four years* later revealed a normal spinal fluid. The blood has continued *negative,* and the patient reported recently *that he felt perfectly* well and never had a recurrence of his former unpleasant symptoms.

Case 9.—*A man, aged 29,* with cerebrospinal syphilis, had had a chancre five years before, and sexual impotence for two years. The left *pupil* was *slightly* larger *than the* right, and both were sluggish to *light; the knee jerks were* hyperactive, the left more so than the right. Otherwise the *examination* was negative. The serum was negative; *the* spinal fluid: cells, 46; *globulin,* + +; Wassermann test, + + + + to 0.6 c.c. Treatment consisted of twelve *intravenous injections* of salvarsan and several courses of mercury and mixed treatment. The sexual power gradually *improved. The blood and the* spinal fluid have been negative for three years.

In such patients there are no indications for intraspinal injection unless they become intolerant to arsenic (sensitization) by the occurrence of skin eruptions, or develop nephritis *or hepatitis. Should the latter* complications occur, we have in intraspinal treatment a reserve method of great value. Intraspinal medication is indicated when the clinical *symptoms* and serologic findings are unchanged after a fair trial of intensive intravenous treatment. I have repeatedly seen patients who have had from thirty to forty injections of salvarsan, with a negative blood but strongly positive fluid and clinical symptoms of nervous system involvement. Only a few days ago I saw a young man whose infection was two years old, who complained of pains in the legs and had beginning Argyll Robertson pupils. He had received thirty-two injections of salvarsan, over 100 injections of mercury, and many inunctions. The blood was negative. Examination of the fluid revealed: cells, *24;* globulin, ++; Wassermann test, ++++ to 0.4 c.c.; colloidal gold test, 1233100000. In these cases it is assumed that the choroid plexus does not permit the remedy to enter the fluid. This assumption is supported by the rapid improvement that follows intraspinal injections. When the blood *Wassermann* test is negative and the fluid test positive it is probable that interchange between the two fluids does not take place. Experience has taught me in such cases that the intraspinal treatment is the one of choice and is followed by results unobtainable by any other. Dr. Sachs' arguments as to positive pressure in the cerebral capillaries, the short contact of remedial agents with foci of disease, and the slow circulation of cerebrospinal fluid are interesting physiologic observations, but have little value in discrediting the results achieved. The logic of results accomplished must always supersede theoretical reasons why they could not occur. I could not convince my patients who have been cured or relieved of their symptoms by intraspinal treatment, after the failure of intravenous treatment, that, theoretically, it was impossible for such benefit to have taken place. They smile at theory in the light of accomplished results.

FINDINGS IN CASE 10

Date	Cerebrospinal Fluid Cells	Globulin	Wassermann	Colloidal Gold Test	Serum
10/31/16	944	++++	++++ to 0.2 c.c.	5555542100	8/12/16 —
11/24/16	90	++++	++++ to 0.4 c.c.	4444430000	10/31/16++++
12/ 6/16	31	+++	++++ to 0.6 c.c.		
12/16/16	30	++	++++ to 0.8 c.c.		
12/30/16	30	+++	++++ to 1.0 c.c.	1133320000	
1/12/17	50	++	++++ to 1.0 c.c.	1123310000	
1/27/17	28	++	++++ to 1.0 c.c.	1123210000	
2/10/17	20	+	++++ to 1.0 c.c.		
3/ 3/17	21	±	± with 1.0 c.c.	1123100000	3/ 3/17 —
3/24/17	18	±	+ with 1.5 c.c.		
4/14/17	8	±	— with 2.0 c.c.	1112210000	
5/19/17	8	trace	— with 2.0 c.c.	0000000000	9/ 6/17 —

Treatment 10/31/16-5/17/17: 6 intravenous injections salvarsan, 11 intraspinal injections salvarsanized serum (Swift-Ellis, fortified with 1/5 to 1/2 mg.), 18 injections mercury.

Certain patients in the early florid stage of syphilis during intensive salvarsan and mercury treatment show symptoms indicating invasion of the nervous system. The spirochetes enter the fluid and produce meningitis or endarteritis with resulting pupillary changes, *monoplegias, optic or auditory neuritis, etc. This early* invasive power of the spirochetes probably indicates a strain different from the usual one. The remedies cannot be given in sufficient concentration through the blood stream to counteract the spinal fluid invasion. Treated in the usual manner, these patients either die *from the intense meningitis* or become candidates for paresis or tabes or other types of cerebrospinal syphilis.

Twenty years ago I saw a woman with a chancre of the upper lip who developed less than six months after the infection a very intense syphilitic meningitis which was *followed* by unconsciousness and death. Dr. Reasoner[2] reported a case of syphilitic meningitis which appeared within six months after a primary lesion and *ended fatally three months later.*

Intraspinal treatment begun at this time acts with *infinitely more* rapidity than in older infections, and offers the only chance of cure and prophylaxis of the later degenerations. Such a case I had the opportunity of treating last year:

Case 10.—A man, aged 45, developed an initial lesion in April, 1916. The Wassermann test when he came under observation, April 26, 1916, was + + + +. He was immediately placed under treatment, and never developed any secondary cutaneous lesions. He had weekly injections of salvarsan and mercury. October 1, while on a business trip, he became very nervous and restless and felt nauseated. *A few days later his right arm* became numb, and for several days he had a transient aphasia. Previously he had had mild generalized headaches for about two weeks. He returned to New York in a few days, and a physical examination revealed a weakness of the right side of the face. The deep reflexes were very active, more so on the right side. *The pupils* were equal, and reacted promptly to light and accommodation. The outlines were very slightly *irregular. On puncture* there were found: cells, 944; globulin, + + + +; Wassermann test, + + + + to 0.2 c.c.; colloidal gold test, 5555542100. The accompanying table illustrates the rapid subsidence of these strongly positive findings under the treatment employed.

METHODS OF DIAGNOSIS AND TREATMENT

A proper conception of the syphilitic infection and the development of an efficient therapeutic procedure cannot be expected from physicians who see *only* the late degenerative effects of the disease. The intraspinal method should not be condemned because it fails to cure advanced paresis. Little can be expected from any method (intraspinal, subdural or intraventricular) in paretics who have reached the stage when institutional treatment is demanded. The future of such patients lies in the hands of physicians who can recognize the early beginnings of the malady and grasp the possibilities of early prophylactic treatment. When cerebral atrophy is present and the entire brain is permeated with spirochetes and their resulting lesions, the most to be hoped for is a modification or temporary arrest in the progress of the disease.

---

[2] Reasoner, M. A.: Early Death from Cerebral Syphilis, with Successful Rabbit Inoculation, The Journal A. M. A., June 17, 1916, p. 1917.

Serologic examination of the fluid in all cases of early syphilis often reveals paresis in its incipient stages when it is amenable to a therapeutic attack. Unless we are to continue hopeless before such cases and watch the slow mental deterioration of the patients, we must employ all the means at our command to ascertain when and how the pathologic process begins and use logical and efficient treatment at the proper time to combat it. The teachers of syphilis in our medical schools must constantly emphasize the possibility of early nervous system involvement and formulate the methods of diagnosis and treatment. In this way and in this way only can we hope to limit the number of cases of cerebrospinal syphilis.

The symptomatology of syphilis of the nervous system is well defined after permanent changes have taken place and the question of relief is more or less uncertain. Early examination of the spinal fluid anticipates future degenerative changes, and permits the use of remedial agents at a time when they can be most effective. To deny the value of spinal fluid examination or to state that it reveals no more than a careful physical examination deprives the unfortunate patient of an accurate insight by the physician into his condition and the institution of efficient therapeusis. The advocates of intraspinal therapy have never claimed that degenerated cords could be restored by any method of treatment. It has been demonstrated, however, that the meningitis which precedes and causes such degeneration can be reached and cured, and further degeneration prevented. In such cases improvement in the clinical symptoms proceeds uniformly with the improvement in the spinal fluid. A patient with tabes whose fluid shows a positive Wassermann reaction with an increase in lymphocytes and globulin can be assured that his symptoms, like pain, crises, etc., may be relieved or cured and the further progress of his trouble arrested. It is true that in some cases the posterior nerve roots may be partially degenerated or compressed in such a manner by sclerotic tissue that pain may persist after all the findings are negative. These are exceptional cases and by no means the rule.

The statement by the author of the paper in question that claims are made for the intraspinal method by men whose chief interest was centered on a change in the Wassermann reaction, in a reduction in the cell count and in a change in the globulin reaction in the cerebrospinal fluid, rather than a change in the clinical condition of the patient, is a severe reflection on the intelligence of such men, and is entirely unwarranted by the facts. The patients are truly the first consideration, and the real object of medical art is to relieve suffering and cure disease. Unless these objects are kept in view, medicine is of purely academic interest and has little concern for the invalid. I have always advocated the close correlation of clinical and laboratory work, and for that reason have developed and conducted a serologic laboratory in which an attempt has been made to eliminate the discrepancies and contradictory reports which are so confusing to the pure clinician. In case the laboratory report does not correctly interpret the clinical diagnosis, an effort is made to ascertain the correctness of the laboratory report or to review or correct the clinical diagnosis. The latter is no more infallible than the former, as we are frequently able to show by laboratory findings that the clinician may be in error. To belittle or deny the value of laboratory investigation in syphilis of the nervous system disregards entirely the careful work of the past, which has thrown so much light on diagnosis and indications for treatment, or as a guide to treatment, and on the nature of the early invasion of the nervous system by the spirochetes.

I agree with the writer that in many particulars the advantages of the intraspinal method have been grossly exaggerated. It has been demonstrated to me very clearly by long continued intravenous and intraspinal therapy that paresis in the stage which comes to the neurologist cannot be cured by any method. Its course is, however, modified more rapidly, and longer periods of remission are secured by intraspinal treatment than by any other. It is questionable, however, if this delay in the downward course of paresis is an advantage to the patient or his family.

The writer's sweeping assertion that the same biologic changes in the fluid have followed intravenous treatment, or repeated lumbar punctures, or the introduction of the patient's nonsalvarsanized serum, I must absolutely deny. I have followed in my own laboratory numerous cases of spinal fluid examination in which no change occurred after the introduction of nonsalvarsanized serum. These spinal fluids were sent for examination and reported on without knowledge by the serologist, Dr. Jagle, as to their origin. I should like to have the author show me a single case in which the Wassermann reaction in the spinal fluid has been influenced by nonsalvarsanized serum or repeated lumbar punctures. The cytology of the fluid may be changed by repeated lumbar puncture, but the other phases are not so influenced. This was demonstrated in my clinic last year where patients were treated over a period of five months by the Ravaut method, that is, the addition of salvarsan direct to the spinal fluid. Excepting variations in the cell count, the fluids *remained unchanged*. The same patients are now being treated with the combined Swift-Ellis-Ogilvie method with very definite results both clinically and serologically. As regards intravenous treatment, it has never been denied that the same fluid changes may not be brought about in certain cases. Those who uphold the advantages of intraspinal treatment maintain and have demonstrated beyond any doubt that in cases not *influenced by* intravenous treatment the intraspinal treatment yields positive results. This is the entire contention, and not that one method or the other can accomplish similar results in unrelated cases.

CORRESPONDENCE OF CLINICAL SYMPTOMS AND FLUID CHANGES

Dr. Sachs states again that there is absolutely no correspondence between a change in the cerebrospinal content and the condition of the patient. To one who approaches the subject with an open mind and is willing to accept evidence, I can demonstrate at least a hundred cases in which there is a very direct relationship between the various phases in the cerebrospinal fluid and the patient's condition. Among them are more than thirty patients with tabes who have been cured of all their distressing symptoms, who have gained in weight and strength, and have regained business and professional activity. Their entire outlook on life has been changed. All these patients presented before treatment positive findings in the fluid. A number of them have been punctured from one to three years after all treatment was discontinued, and now show normal fluids. These patients may be definitely regarded as cured, as far as any further degenerative change is concerned. Ten patients with optic atrophy after one to two years show enlarged or stationary visual fields, and now have normal fluids; whereas before treatment all the phases were positive, including a cell count of from 24 to 150. The examinations of the eyegrounds and visual fields in these patients were made by ophthalmologists whose statements cannot be doubted.

In early syphilis with active meningitis, the symptoms rapidly subside with improvement in the pathologic fluid. In paresis and preparetic conditions a temporary remission may occur which is not indicated in the fluid excepting in the cell count and sometimes the globulin. In other cases, cerebral disintegration proceeds rapidly while the biologic condition improves. An active meningitis in these cases is influenced by treatment and registered in the fluid examination; but the deeper lesions progress as indicated in the failing mental powers. . I could demonstrate many cases of paresis and taboparesis in which the Wassermann reaction remains persistently positive after two or more years of intravenous and intraspinal injections; but observations like these should not discredit established facts and lead to the rejection of the invaluable information that is afforded by this kind of investigation. We have learned that a fixed or persistent positive Wassermann reaction in the higher dilutions indicates in the majority of cases a potential paresis. Such observations properly interpreted support rather than detract from the value of the biologic tests.

In tabes, excepting in abortive forms and the terminal stages of long standing cases, in meningitis and meningo-endarteritis, the clinical symptoms correspond fairly closely with the serology, receding or advancing with corresponding changes in the fluid. Improvement in the Wassermann and globulin reactions may appear slowly and show the results of treatment long after the clinical picture improves.

The relationship of the Wassermann reaction to skin and visceral lesions is analogous, for large nodular skin lesions may entirely disappear after a short treatment, while the serum reaction shows positive for a much longer time. We persist in treatment until the reaction is modified or becomes negative, to guard against a possible relapse. The same sequence is encountered in the central nervous system; namely, a marked improvement in symptoms, persistence in the Wassermann and globulin reactions, a relapse after the discontinuance of treatment, then further treatment, until finally a negative fluid is obtained, with no further relapses. We have seen this succession of events so frequently that we urge treatment until we obtain negative findings or are convinced that the persistence of a positive Wassermann reaction in the high dilutions of the fluid with a paretic curve indicate approaching paresis.

No consistent or permanent results will be achieved in the treatment of syphilis of the central nervous system until the correction of the clinical symptoms and biologic changes are appreciated by the physician under whose care these patients come. A correct and comprehensive grasp of the problem will come only to the one who has the opportunity over a period of years patiently to study and correlate the clinical as well as the laboratory side of the question. It would be unfortunate, indeed, for the victims of syphilis of the central nervous system if the views of Dr. Sachs as to the value of spinal fluid examinations were to prevail and our diagnostic and therapeutic methods revert to the time before Nonne showed the great value of such examination in disease of the central nervous system.

EXAMINATION OF THE FLUID

A systematic fluid examination in all stages of syphilis has thrown much light on the time when infection of the fluid occurs. It has indicated the probable time when the spirochetes are deposited in the cerebral tissues and in the spinal fluid which later cause paresis and tabes. It has given us a working hypothesis that offers hope to these unfortunate patients and enables us to anticipate the degenerative stages. A general appreciation of this theory of the nervous system infection will do much to lessen the number of incurable paretics and tabetics, and relieve our public and private institutions of the enormous expense of caring for them. As a result of accumulated experience, I have learned to place vastly more reliance on spinal fluid examinations in determining the progressive or stationary character of the infection and the prognosis that can be offered the patient, than from the objective or subjective manifestations that these patients present.

Among our tabetic cases we find a group which shows little or no change in the spinal fluid, while presenting typical Argyll Robertson pupils and changes in the deep reflexes. These cases we look on as abortive or rudimentary tabes in which the process has cured itself or has been influenced by the previous treatment that the patients have received. There is, of course, here no indication for intraspinal injections. In other words, the fluid must show pathologic changes before we are justified in introducing our remedies by this channel. The same argument applies to optic atrophy. If we find a relatively high cell count with other phases positive, we assume that the meningitis which has involved the optic tracts or nerves may be influenced by the treatment employed.

IMPORTANCE OF PROPER TECHNIC

The criticism and opposition to the method are largely due to the unfortunate results that followed the employment of the Ravaut technic, that is, the introduction of from 1 to 5, 6 or more milligrams of neosalvarsan added directly to the spinal fluid. A number of cases so treated have come under my observation with a traumatic myelitis causing bladder and rectal paralysis and with, in some cases, complete and permanent paraplegia. We have gradually learned, however, the tolerance of the cord to the remedial agent, and have evolved a technic that is free from the dangers mentioned. We have learned that low tabes with advanced degeneration will tolerate only the smallest doses, or is best treated by the original Swift-Ellis method. In high tabes or when the degeneration is of light grade, and in paresis, relatively larger doses can be used and at more frequent intervals. We have learned, too, that less irritation is produced and more benefit follows if we permit about 20 or 25 c.c. of fluid to accumulate in the receptacle attached to the spinal puncture needle and then add our salvarsanized serum to it. In this way it is diluted before entering the subarachnoid space. Two objects are accomplished by this procedure: first, the minimum of irritation, and second, the withdrawal and medication of a larger quantity of spinal fluid. If we medicate a larger amount of the spinal fluid, we believe in replacing it that it will reach more readily the more accessible perineuronal lymph spaces. Our results in optic atrophy and in cerebral meningitis support this supposition.

It is needless to say that the proper employment of a procedure so highly technical as this one requires the aid of trained assistants and a well equipped laboratory. It requires the judgment gained by experience as to the dose to be used and the intervals that should elapse between them. Rest periods between courses of injections are also important, so that we may properly estimate the clinical and serologic improvement. During the past three or four years we have given hundreds of injections with no deaths and with no more serious symptoms than those that follow an ordinary lumbar puncture. Many patients prefer the intraspinal treatment to intensive intravenous treatment, as the constitutional reaction is generally less marked. In cases treated intravenously in the intensive manner mentioned by Dr. Sachs, I have seen severe and fatal forms of generalized exfoliative dermatitis, persistent forms of gastro-enteritis, nephritis and obstinate cases of jaundice due presumably to fatty degeneration of the hepatic cells. The intraspinal treatment can be used without subjecting patients to these dangers, and aside from the advantages of the method and properly selected cases it is a valuable reserve treatment in patients who have lost their tolerance to salvarsan intravenously or who have developed arsenic dermatitis, nephritis or hepatitis. In acute cases of early meningitis it is the method of choice.

CONCLUSIONS

1. In tabes, certain types of cerebrospinal syphilis like meningitis, meningo-myelitis, meningo-encephalitis and in optic atrophy with positive findings in the fluid, intraspinal treatment succeeds in relieving or curing the conditions after failure of intravenous and other treatment.

2. It is the only procedure that can be employed after the intravenous treatment fails or when the patient develops an intolerance to arsenic.

3. With proper technic and experience, it is less dangerous than intensive intravenous treatment.

4. In paresis with stigmata of degeneration, the most to be hoped for is temporary arrest of the encephalitis. There are borderline cases of meningo-encephalitis which simulate paresis and which are curable by the treatment in question.

5. The criticism of the method is based largely on the results following imperfect technic and by its employment in cases without clear indications afforded by spinal fluid examination. Aside from these reasons, it has been condemned after short and imperfect trials. In some cases the existing lesions are activated by early injections and cured by persistence in the treatment.

6. The author's statement that it is regrettable that changes in biologic findings should be made the criterion of the efficiency of any therapeutic method is unfortunate from the standpoint of the patient as well as the investigator. With the exceptions noted in the body of the article, there is an intimate relationship between the clinical symptoms and the fluid findings. It is not difficult to select individual cases in which the Wassermann and globulin reactions are unchanged after prolonged treatment; but conclusions based on such exceptional cases are one sided, unfair, and fail entirely to interpret or correlate the fundamental principles involved. If reliance is placed on clinical improvement alone as a criterion of the action of our remedies and the fluid changes disregarded, few, if any, permanent cures will be achieved, and sooner or later the patient's condition will relapse. There is as much reason for basing the efficiency of a therapeutic procedure on the changes in the biology of the fluid as there is in using the blood Wassermann as a test of the value of treatment of syphilis in general. If we were to discard the positive knowledge acquired in the past few years as a result of systematic examination of spinal fluids in syphilis, we should have vague ideas as to the time the fluid is infected, no clear conception of the difference between active and abortive tabes, and no method of differentiating early paresis from conditions that simulate it. Neurasthenic states, headaches, phobias, vague changes in mentality, crises, or impairment in the sexual function are constantly overlooked or wrongly diagnosed by the pure clinician. Arteriosclerosis, chronic alcoholism, and diabetes may cause symptoms easily mistaken for the syphilitic syndrome.

7. The future of the syphilitic individual and the hope of anticipating or arresting the incurable degeneration is largely dependent on early and systematic examination of the spinal fluid.

ROENTGENOGRAPHIC EXAMINATIONS OF THE URINARY TRACT

REVIEW OF A SERIES OF ABOUT 500 CASES *

E. W. CALDWELL, M.D.
NEW YORK

This paper presents the results (some more and some less completely) obtained in 500 consecutive roentgenographic examinations of the urinary tract occurring in private practice. These cases were referred by 230 different physicians or surgeons, and it has been impossible to obtain full clinical records of all of them.

It will be appreciated that the accuracy and the extent of the clinical observations made by so large a group of men will vary considerably, and that the data derived from them cannot compare with the information which may be obtained from a hospital in which all of the work is done by a comparatively small group of men accustomed to working together.

In a few of the examinations, pyelography was combined with the ordinarily roentgenographic examination; but the number of these cases is small, and they have not been considered in this series. In a few cases our own records are incomplete, and these have been rejected from the series. Sometimes our records have been borrowed and not returned. There remain 455 cases of which we have fairly complete records of the

roentgenographic reports. No case has been rejected from the list in which it is even suspected that an error was made in the roentgenographic diagnosis.

In practically every case, the report of the examinations was made from the roentgenograms alone and without taking into consideration the clinical history, the symptoms or the urine investigation. The results are, therefore, what may be obtained with the roentgenograms alone, not aided by pyelography and without any clinical help.

It must be obvious that some of the errors recorded might have been avoided had we used the combined method, and some of the cases reported doubtful or indeterminate would probably have been reported positive had we been in possession of the clinical data. On the other hand, it is likely that in a certain number of the doubtful or indeterminate cases, the possession of the clinical data might have led us into positive statements which would later have proved incorrect.

In order to allow sufficient time for subsequent observation, no examinations made later than Dec. 31, 1916, are included. All examinations in this series were made during 1914, 1915 and 1916, a period in which the technic was practically the same as that of today. The results, therefore, represent fairly what may be expected under present conditions from roentgenographic examinations alone. Before the beginning of the war, the photographic materials available were much more reliable than now, and the accuracy of results obtained in these examinations was somewhat greater.

In order to check up the results of the roentgenographic examinations and to obtain clinical data, the following questionnaire was recently mailed to every physician or surgeon referring a case in this series:

Date of roentgen-ray examination:

1. Was the roentgen-ray examination helpful to you in diagnosis?
2. Has the patient been operated on?
3. What did operation disclose?
4. Result of cystoscopy, if any:
5. Were calculi passed?
6. Did urine contain: (*a*) Blood? (*b*) Pus? (*c*) Tubercle bacilli?
7. Were symptoms due to lesions outside of urinary tract: (*a*) Appendicitis? (*b*) Oophoritis? (*c*) Salpingitis? (*d*) Colitis? (*e*) Gallstone? (*f*) Other causes?
8. Any additional information bearing on the accuracy of the result of the roentgen-ray examination:

The results of the roentgenographic examination of the whole 455 cases have been tabulated and are presented here, but we have succeeded in obtaining clinical data in only about 290 of these cases and some of these replies are incomplete. We have, however, accepted no reply which does not give a satisfactory answer to the question regarding the presence or absence of calculus.

The chief thing sought in these examinations is to determine the presence or absence of calculus. In the 455 cases of which we have complete records of the roentgenographic examinations, calculi were reported in 119 cases. In 314 cases no calculi were reported, and in twenty-two cases there were suspicious shadows which we reported as doubtful. The plates of some of these doubtful cases presented shadows which could be explained either by urinary calculi or by extra-urinary calcareous bodies. In all of these doubtful cases it was recommended that additional examination be made with the opaque ureteral catheter in the ureter, but in most of them this procedure was declined as unnecessary. In a few of the doubtful cases, the plates were not satisfactory because of incomplete preliminary clearing out of the digestive tract. Whenever possible, additional plates were made to correct these defects, but there remain some cases in which it was impossible to obtain an additional examination. In more than half of the unsuccessful and doubtful cases, we could not make the examinations as complete as we desired.

Of the 119 cases in which calculi were reported, twenty-two presented two or more calculi. The total number of calculi reported was 158. Of these, thirty-eight were in the left kidney; thirty-seven in the left ureter; thirty in the right kidney; twenty-eight in the right ureter; nineteen in the bladder, and six in the prostate. Of the 119 calculus cases, forty-nine were proved correct, either by operation or by the passing of calculi. In the remaining seventy of these cases we have been unable to obtain definite information that the calculi have actually been seen. We have regarded no case as proved unless the calculi have been recovered.

We have been unable to obtain reasonable evidence that there was any error in the diagnosis of calculus in any of these 119 cases reported positive. Of the doubtful cases, calculi have been demonstrated by operation in two cases and by passing of stone in three cases. In the remaining seventeen, we have no information as to calculus, but other probable causes for the symptoms have been reported in most of these.

Of the 314 cases in which the roentgenographic examination was reported negative for calculi, stones have been subsequently passed in five cases. In two cases stones were removed by operation. We have, therefore, seven proved errors in the series of 455 reports, a percentage of about 1.5 of the total number of cases examined. Perhaps it would be more accurate to reckon this percentage as 2.4 per cent. of the 290 cases in which we were able to obtain satisfactory replies to our question blank.

The more I have worked on these tables of statistics, the more I have been impressed with the impossibility of obtaining absolute accuracy. There are doubtless some errors in the clinical records that have been kept. Another source of error which has been difficult to avoid is that in several cases in which the report of the roentgenographic examination was negative, we were told that stones had been removed by operation, but on more careful investigation it was found that the calculi were passed or removed by operation prior to the time of the roentgenographic examination. This difference in the date was in some cases overlooked by the attending surgeon, who reported us in error, when in reality no mistake was proved.

Comparisons have frequently been made between the expert statistician and various kinds of liars, always to the disadvantage of the statistician. Since preparing this paper, my sympathies are all with the statistician.

While the chief function of the roentgen ray in examinations of the urinary tract is to determine the presence or absence of urinary calculus, other useful or interesting information is incidentally obtained. In many of the cases reported some information was given as to the size, outline, position or density of the kidney shadow. In this series there were reported such anomalies as sixty-two in size of kidney, seventeen in outline, fifteen in position and thirteen in the density of the kidney shadows. In a few of these cases the abnormalities of the kidney shadow were proved to be connected with a pathologic condition of the kidney.

In the course of these examinations many other calcareous bodies were shown in the neighborhood of the urinary organs. In this series we have reported eighty cases with phleboliths, ten with calcified mesenteric glands, three with intestinal concretions, and seven with gallstones.

Pathologic conditions of bones and joints are frequently observed in the course of examinations of the urinary tract. In this series there were reported forty cases of ostearthritis and five cases of other disease of the bone or joint. It seems likely that in a few of these cases, disease of bones or joints was the cause of the symptoms; but we are unable to obtain accurate data as to the number.

Anomalies in the development of the lumbosacral region are not uncommon. While these anomalies may be of only academic interest, they are shown perfectly well in roentgenographic examination of the urinary tract, and I think they should always be noted, since they may occasionally be proved to have an important bearing on the symptoms. In some of these cases it was found that one or both transverse processes of the fifth lumbar vertebra were enlarged and articulated with the sacrum and ilium. This anomaly is commonly described as sacralization of the fifth lumbar vertebra. We have noticed that a number of these patients presented the symptom of persistent pain in the back after some strain or unusual exertion, when no other cause could be found to account for the symptoms. This pain has been most frequent in cases in which there is unilateral sacralization. The pain is usually felt on the side opposite the sacralization.

In another class of anomalies, of which ten are reported in our list, there was incomplete union of the first sacral vertebra with the rest of the sacrum.

In some of these cases there were six vertebrae without ribs, between the twelfth dorsal and the sacrum. In others there were only four vertebrae in this region without ribs.

The answers to some of the other questions in our blank are given below. In answer to the first question as to whether the roentgen ray was helpful in diagnosis, 216 replied "Yes," and forty-four "No." In the remainder no answer was given. On looking over these replies we are impressed with the fact that the answer to this question was purely a subjective matter and depended somewhat on the weather or the state of digestion of the person answering. Many answered the question in the affirmative when our report of the roentgen-ray examination was negative and seemed to me of no value. In other cases in which the roentgen-ray examination gave much definite information as to size, number and position of calculi, the reply was that the roentgenographic report was not helpful.

The answer to Question 2 of our blanks showed that of the 290 patients concerning whom we have clinical data, seventy-two were operated on and 190 were not operated on. In forty-three cases cystoscopic examinations were made, and in 202 cases no cystoscopy was made. Calculi were passed in twenty-two cases, and in 229 cases it was reported that no calculi had passed.

The replies showed also that of the negative cases symptoms were accounted for by appendicitis in six; by ovaritis or salpingitis in six; by colitis in one; by gallstones in seven, and by other causes in nine cases.

In 242 cases the urine examination showed blood, and in 247 cases pus was shown.

In the forty-nine cases in which calculus was proved by operation or by passing the stone, the urine examined showed blood and no pus in seven cases; pus and no blood in two cases; both pus and blood in thirteen cases; neither pus nor blood in three cases, and in six cases no report. Of the remaining seventy cases reported positive for calculus, but not proved by operation or passing of stone, two presented blood and no pus in the urine; two pus and no blood; ten presented both pus and blood; three neither pus nor blood, and in forty cases there was no report. Of the five cases in which the roentgen-ray examination was doubtful, but in which the presence of calculi was proved, both pus and blood were found in the urine of two; one presented blood only, and one had no pus or blood and on one there was no report. Of the doubtful cases not proved positive, two had both pus and blood; three pus only; two blood only, and five neither pus nor blood, and five were not reported. Of the cases in which the roentgenogram was negative, nineteen revealed blood only; twenty-five pus only; fifty-four both blood and pus, and sixty-eight no blood or pus.

It will be observed that of the cases in which the presence of calculus was proved, about 52 per cent. presented both blood and pus in the urine. In these cases only 12 per cent. presented neither blood nor pus in the urine, and of those cases reported negative, nearly 41 per cent. presented neither pus nor blood.

The preparation of the data in this paper has impressed me with the difficulties of obtaining complete statistics of cases occurring in private practice, but I trust the results given will not warrant the usual uncomplimentary classification of the statistician.

I find that the number of our errors in the diagnosis of urinary stone is about twice as large as I had supposed, but the percentage is still smaller than that which is reported from examinations made in various hospitals or clinics. It is possible that if all the errors could be known, the percentage would be much higher; but I doubt it. A higher percentage of accuracy should be expected in private practice than in hospital or dispensary work. The success of the roentgen-ray examination for urinary stone depends largely on the intelligent cooperation of the patient. The average hospital or dispensary patients, especially those who speak some unknown foreign language, cannot be depended on to cooperate thoroughly in the success of the examination. They are very prone to breathe or to move during the exposures. In private practice more time is usually given to these examinations, and more plates are made. The economy practiced in most hospital roentgen-ray departments undoubtedly results in the sacrifice of accuracy. The duplication of plates and the use of the stereoscopic methods are not commonly employed in hospitals, and these procedures undoubtedly lessen the number of errors.

It is possible that the mode of life of some of the foreign population which forms a bulk of certain dispensary patients conduces to the formation of uric acid or urate calculi which are not readily demonstrated by roentgenograms. A small percentage of error must be expected even under the best conditions, but we should remember that there is no absolutely infallible method of diagnosis of urinary stone.

480 Park Avenue.

CLINICAL DIAGNOSIS OF LITHIASIS OF THE UPPER URINARY TRACT *

EDWARD L. YOUNG, Jr., M.D.
Genito-Urinary Surgeon to Outpatients, Massachusetts General Hospital
BOSTON

If in this symposium the word "clinical" is to be used in distinction from "roentgen-ray" diagnosis, I shall have to throw up the sponge at once, because the absolute diagnosis of stones in the kidney or ureter without the use of the roentgen ray is impossible. A stone may be present anywhere in the upper urinary tract, either without giving any sign or symptom of its presence, or on the other hand, it may present any of a great variety of signs and symptoms such as would point to any of the various urinary troubles, or even such as would strongly suggest a diagnosis far removed from the urinary tract. Then again, a patient may present what we have been pleased to call a "typical" story of renal colic, bladder irritability, etc., and even show pus and blood in the urine, and yet no stone be present. This is nicely shown in a table by Eastmond as given by Keyes. In a series of eighty cases, sufficiently suggestive of stone to require roentgenographic examination, only twenty-three were positive, and of these, only eight patients complained of the so-called typical symptoms. On the other hand, of the fifty-seven which showed no stone, forty-four did have typical symptoms and in addition, thirty showed either pus or blood, or both, in the urine. In fact, according to this table, there is a better chance of finding a stone if the symptoms are indefinite than if they are typical, as only 24 per cent. of the latter had calculi, while 40 per cent. of the former were positive.

In a recent study by O'Neil of 273 cases in the Massachusetts General Hospital in which a preliminary diagnosis of nephrolithiasis was made, the same discrepancy was revealed between the original diagnosis and the real lesion. One hundred and thirty-three of these were house patients, and of this number, twenty-eight were proved to have no stone. Of these, no diagnosis could be made in four cases. The remaining showed a variety of lesions: Hydronephrosis, kinked ureter, movable kidney, and pyelitis were present eight times, while nephritis, appendicitis, gallstones, arteriosclerosis, abdominal glands, vesical calculus and chronic lead poisoning accounted for the rest. Of the 140 cases which got no farther than the outpatient department, more careful study showed only twenty-five with positive findings. The final diagnosis in the remaining 115 cases was as follows: Orthopedic lesions, such as back strain and sacro-iliac strain, accounted for thirty-six; no demonstrable lesion could be found in seventeen; genito-urinary lesions, including nearly every diagnosis, covered twenty-seven, while the rest were scattered far and wide from constipation to syphilis, and from hernia to tabes. Nearly every one who has written anything on this subject gives the same story.

From these two tables it seems that symptoms in themselves are merely suggestive at best and may even be misleading. A careful urinalysis likewise may lead us astray, but almost always in one direction. The presence of abnormalities may suggest a urinary lesion which is really not present, but a persistently normal urine in the presence of stone is more uncommon, although still to be reckoned with. In 150 cases in which the urine was carefully examined, Cabot reported persistently negative findings in twenty-one; of these, fifteen were ureteral stones and six renal. It seems almost needless to emphasize the fact that in the female, only a catheter specimen has any value, and that a centrifuged sediment should always be examined even in the absence of albumin.

A good roentgenogram is at the same time our best evidence as to the presence or absence of a stone, and likewise the stumbling block most likely to lead us into trouble, for implicit faith in roentgenography, without the confirmation of other means of diagnosis, will often carry us into needless, even disastrous operations; for the misleading evidence most often presented is the presence of a shadow very suggestive of stone, but which in reality has nothing to do with the urinary tract. The percentage of failure to show a stone which is present is very small if the case is in the hands of a good man, and is variously stated to be from 6 to less than 1 per cent. If the roentgenogram reveals a shadow which, in view of other attendant signs and symptoms, probably represents a stone, it still must be proved by means of stereoscopic plates taken with an opaque catheter in the ureter. A single plate is of value, but occasionally a calcified gland may lie in front of the ureter or kidney in such a way that without stereoscopic plates we cannot discover that it is not at all connected with the urinary tract. If the shadow is in the kidney region, two plates taken, one during quiet expiration and the other at the end of forced inspiration, answer much the same purpose.

If the ureter catheter meets an obstruction in the ureter at a distance from the bladder corresponding to the distance on the plate, and other characteristic signs and symptoms are present, the diagnosis is almost certain, but not quite. Cabot speaks of two cases in which a tuberculous gland in the mesentery of the large intestine caused pressure on, and obstruction to, a ureter with dilatation above. In such a case, stereoscopic plates and obstruction to a catheter will fail to make the diagnosis. The use of a wax-tipped catheter, in the hope that any stone present will make its mark, is likewise doomed to failure. But the injection of the ureter above the obstruction, and the demonstration of a dilatation, will show the need of operation to relieve pressure, and in spite of our inability to make an absolute diagnosis in these cases, we are consoled by the thought that operation is necessary. In case a stone is in that portion of the ureter opposite the sacro-iliac joint, it has been demonstrated by Dodd and Cabot that it may fail to show in the roentgenograms even though it is of considerable size and density. In these cases, a careful study with the wax-tipped catheter is necessary, and likewise an injection of the ureter above the obstruction is often of value,

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

provided the obstruction is not too great to allow the passage of fluid. The latter procedure, which was condemned as being unsafe a few years ago, is today rendered nearly if not quite harmless by the use of either silver iodid emulsion or thorium. There is finally a small group of patients who have suggestive symptoms, a roentgenogram showing a shadow which might be a stone low in the ureter, with a normal or only slightly abnormal urine, and a ureter opening which will not admit a catheter. Cabot reported two such cases, and I have seen one since. In the last case, I cut the ureter opening freely with the operating cystoscope and still failed to get a catheter in more than a quarter of an inch. A wax-tipped catheter showed no marks, but as I have, on other occasions, failed to get anything conclusive when the catheter met a stone head on, I did not consider it good negative evidence. Operation failed to show a stone, and though some stenosis was apparently present, it did not seem enough to have entirely blocked a ureter catheter, or to have caused the symptoms.

With a shadow in the kidney region, the wax-tipped catheter is still less to be depended on, since a stone in any one of the lower calices will not be touched by a catheter, and accordingly no record will be left on the wax.

Some authors speak of the use of collargol injected into the pelvis and rendering visible a stone previously invisible. Although I have tried this method, using silver iodid emulsion instead of collargol, and have seen it tried several times, I have never seen it work.

Thus we see that in order to make an accurate diagnosis even of the presence or absence of a stone, we must use all the means at our command; but when we have done this, it is not enough, for the best interest of the patient demands that we should likewise find out the following facts: (1) the presence or absence of another kidney together with its functional ability; (2) the amount of damage done in the kidney having the stone, and (3) the position of the stone in the kidney. In order to do this, the use of other tests, as well as those already spoken of, is necessary. Urinalysis will disclose the presence or absence of any gross damage by its appearance, odor, amount of pus and albumin, and a stained sediment and culture will reveal the type of infection, if any. As stone and a negative urine are perfectly compatible, the presence of the latter is of value only in showing the absence of any damage or infection.

Cystoscopic examination will reveal the presence of another ureter opening which is functioning, and the passage of a catheter will allow the demonstration of the presence or absence of infection and the functional capacity of the well kidney. It is often important, especially in those cases in which previous examination indicates that operation is going to be difficult, to know as accurately as possible in which calix the stone is situated. This can be told very well by having one roentgenogram followed immediately by another, without moving the patient, and with the pelvis injected for the second picture. The second roentgenogram gives us also valuable information as to the amount of destruction of the kidney that has taken place. In fact, it may be the only thing which gives us a real indication of this damage. For even a large calculus pyonephrosis may not show on urinary examination the amount of pus we should expect, and because the presence of a stone can cause a reflex inhibition on the functional capacity of the kidney, a very low red test cannot always be relied on to prove the amount of damage it suggests. But when a roentgenogram reveals several stones at the lower pole of the kidney and then a second roentgenogram with the pelvis injected shows not only a grossly dilated lower calix but also a thinning of the cortex at the upper and middle calices, we may consider a nephrectomy the probable operation of choice. In those cases which present a single calix much enlarged and the cortex over it thinned as shown by the roentgenogram, with pelvis injected, we can be confident that a small nephrotomy opening will be our best mode of operation. But even with these procedures, a sufficiently accurate diagnosis as regards the condition of the kidney cannot be made to justify our promising to take out the stone and leave the kidney, as I have had one or two patients demand. Since a destroyed kidney may shut down around a single large stone, not only is the amount of pus very small, but the roentgenogram with injected pelvis discloses no gross dilatation of the pelvis, even though it is absolutely abnormal.

DIFFERENTIAL DIAGNOSIS

In the genito-urinary clinic of the Massachusetts General Hospital, it is fairly common for a patient to be referred with diagnosis of stone, with pain or colic typical in character and with pus and albumin in the urine, whereas a careful examination reveals tender, distended, nodular, seminal vesicles, no pus from the kidneys, and a negative roentgenogram. Treatment of these vesicles cures the stone. Two or three patients have volunteered the information when a finger was pressing on the vesicles, that "there is the pain now." I thought this was conclusive until a short time ago when I examined a patient who volunteered such a statement and found on roentgen-ray examination the shadow of what proved to be a large ureteral stone about half an inch from the bladder opening on the side corresponding to the one tenderest on pressure. Generally the colic of seminal vesiculitis is lower down in the back than the renal colic, and follows the crest of the ilium in a more characteristic fashion.

From a review of these cases of mistaken diagnosis it is evident that the appendix has been the greatest sufferer when error has been made. That a certain number of appendixes must inevitably be sacrificed in case of doubt is due to two facts too well known to require comment: 1. An acute suppurating appendix may be present without a corresponding amount of tenderness and rigidity. 2. A considerable amount of microscopic blood may be present in the urine, due to the pressure of an acutely congested appendix on the ureter. In cases of doubt, therefore, the appendix should be removed if for any reason it is not possible to take the time, or the apparatus is not at hand, to make a more accurate diagnosis. I have recently known a case in which a very good surgeon did delay operation in case of doubt with a resulting fatal peritonitis, so that I am sure it is much better to take out an innocent appendix than leave a guilty one. But the same thing cannot be said for other intra-abdominal lesions which do not require an immediate decision, and certainly it seems not only inexcusable but almost criminal to subject any person to operations such as are shown by the following two cases. The first patient, who showed five stones in the right kidney, had at the first operation a dilation and curettement. At the second operation the right ovary was removed and at the third operation the left ovary was removed. The second patient had (1) an operation for gallstones, though the gallstones were not found; (2) an appendectomy and a resection of the right ovary, and (3) a ventral fixation of the uterus. Not until eight years after the first operation was it discovered that a stone only three-quarters inch in greatest diameter was blocking the right ureter.

The cases that are complicated by orthopedic lesions are among the most interesting and likewise the most difficult to straighten out because it is seldom that an orthopedic surgeon cannot find postural strain, ptosis, or flatfoot; but whether the real diagnosis be urinary or orthopedic the patients may present themselves to either surgeon.

In the series of cases at the Massachusetts General Hospital previously spoken of, thirty-six cases in which the first diagnosis was renal stone showed orthopedic lesions, of which postural strain and abnormality of the fourth and fifth lumbar vertebrae made up fourteen, the remaining being spread among flatfoot, ptosis, scoliosis, hypotrophic arthritis of the spine, back strain and sacro-iliac strain. In four of these cases the urine was remarkably abnormal; in spite of a negative roentgenogram it seemed difficult to attribute all of the trouble to the orthopedic diagnosis, and it was thought possible that a small stone had been present and passed before the patient was seen. In twenty-four cases there were urinary symptoms, and of these cases the urine was normal in fifteen, so that nothing in the urinary tract could have been the cause of these symptoms. Moreover, some of these patients were relieved of their urinary difficulties when their orthopedic troubles were corrected. The relation between an abnormality of the back and urinary frequency is not at all understood and, indeed, very seldom recognized; but it certainly does occur, and when accompanied by pain and perhaps a suspicious roentgenogram it may lead us far astray. The following case is a good example: Miss X came for relief of urinary frequency and pain low in the left side, sometimes coming on in attacks. A diagnosis of ureteral stone had been made but never proved. The urine was normal; cystoscopic examination revealed a slight reddening around the left ureteric orifice, and the ureter would admit only a No. 5 catheter, but that perfectly freely. No stone could be demonstrated. The orthopedic consultant found marked postural strain, and after the use of proper support and exercises, the frequency and pain both disappeared.

CONCLUSIONS

No single piece of evidence, or combination of evidence, is sufficient to make an absolute diagnosis of a renal or ureteral stone. All chance of mistake should be excluded by using ureter catheters, wax-tipped catheters, stereoscopic plates, and roentgenograms with injected pelvis.

In all cases with indefinite symptoms, such as recurrent or chronic pain in the abdomen or back, even when a definite orthopedic abnormality is present, careful, repeated examination of the urine should be made, including a microscopic examination of centrifuged sediment, regardless of the presence or absence of albumin. In the female, such examination is of value only when the urine is obtained by catheter. Whenever operation is considered in any one of this group of cases, roentgenoscopy in addition to the foregoing examination is necessary.

87 Marlboro Street.

A CLINICAL STUDY OF LITHIASIS

BASED ON A SERIES OF ONE HUNDRED AND NINETY-EIGHT CASES *

HENRY G. BUGBEE, M.D.
Fellow of the American College of Surgeons
NEW YORK

In urinary lithiasis our plan of action depends entirely on an analysis of the individual case, and the degree of our success in the treatment will be proportionate to the completeness of our understanding of the pathology presented.

An analysis of 198 cases which I have studied in hospital and private practice forms the basis for certain deductions relative to the formation of urinary calculi, the clinical picture presented, and a general outline of treatment.

Of the 198 cases, 111 were in males, 87 in females. Excluding the cases of calculi of the lower urinary tract, 12 of which occurred in females, there were 73 males and 77 females with calculi of the upper tract.

These figures are at variance with recorded statistics. The usual larger proportion of males is probably due to the fact that more women with urinary symptoms consult the gynecologist than the urologist, and a fair comparison could not be obtained.

INCIDENCE ACCORDING TO AGE

Age of Patients	No. of Cases
1 to 9 inclusive	1
10 to 19 inclusive	3
20 to 29 inclusive	32
30 to 39 inclusive	55
40 to 49 inclusive	43
50 to 59 inclusive	29
60 to 69 inclusive	28
70 to 79 inclusive	5
80 to 89 inclusive	2
Total	198

The relatively large number of patients past middle life presented vesical calculi.

In the formation of urinary calculi, two predisposing factors have stood out most prominently. These are (1) a gastro-intestinal disturbance, and (2) disturbed drainage along the urinary tract. The question seems to be more one of body elimination than one of intake.

The most important pathologic condition of the gastro-intestinal tract in this relation to lithiasis is some degree of stasis. The causes of stasis can be ascertained only by a study of the entire alimentary tract.

Through intestinal stasis, the chemistry of the blood supplied to the kidney is altered and bacteria in large numbers enter the urinary tract.

The effect of disturbed drainage of the urinary tract is most easily studied in the bladder. The rapidity with which decomposition takes place and calculi form when residual urine accumulates, we have all noticed in cases of vesical obstruction with retention. There is no reason why the same action does not take place in the kidney.

Interference with kidney drainage is most often due to abnormal mobility. The mobility may be slight and still cause a kinking at the ureteropelvic junction if the ureter is fixed. Of the 77 females showing calculi of the upper urinary tract, in 51 the calculi were on the right side, in 22 on the left, while 4 were

bilateral. In 39 of the right-sided cases, and 11 of the left-sided, a certain degree of mobility, interfering with drainage, could be demonstrated.

As all ureteral calculi are probably renal in origin, they may be grouped together in this consideration.

In the males, twenty-eight were right-sided, thirty-eight left-sided, and five bilateral. Unfortunately, in but few of these cases was the renal mobility ascertained, but in several it was strikingly marked. One patient presented a pelvic kidney, and several others showed a well-marked prolapse. Abnormal mobility will no doubt be demonstrated more frequently in males if more careful examinations are made. Palpation which fails to reveal the lower pole of the kidney on deep inspiration does not exclude this possibility. Better muscular development in the male interferes with palpation. Recently, during the examination of a patient, a kidney which could not be palpated on deep inspiration dropped to the brim of the pelvis while the patient was standing erect.

Three patients with renal calculi gave a history of injury. One patient presented a calculus with hypernephroma.

The symptoms presented by renal calculi may be of so slight a nature as to pass unnoticed for many years, as in the following cases:

Case 1.—A man, aged 33, had had a vesical calculus removed three years previously. He came for consultation for vesical irritability, suspecting another vesical calculus. Investigation disclosed a branching calculus completely filling the pelvis and calices of both kidneys. The patient positively refused operation, saying he had had no pain or discomfort.

Case 2.—A woman, aged 65, entered the hospital with the diagnosis of appendicular abscess. A definite mass was palpable in the lower right quadrant. An examination of the bladder revealed an obstruction of the right ureter with thick pus. On dislodging the plug in the ureter, and by gentle pressure on the abdominal mass, 16 ounces of thick, foul-smelling pus were evacuated through the cystoscope. Exploration of the abdomen showed a calculus the size of an orange in a shell of a kidney.

How long the calculus had been present in these cases, and in many similar ones, one cannot say. I recently removed a calculus from the left kidney pelvis of a man, aged 34, who was sent to me to be treated for a chronic urethritis. There were no symptoms referable to the kidney, although the kidney pelvis was so surrounded by lymph exudate and fat that the calculus resembled the stone in the center of a peach. The vesical irritability entirely disappeared after the removal of the calculus.

Pain is the most constant symptom of renal calculus, and was present in some form in thirty-five of forty-three patients. In renal calculi the pain was never severe, except when the calculus was small and located in the pelvis or in a calix, so as to interfere with the urinary flow, thus increasing intrarenal tension.

A dull ache localized in the costovertebral angle was the most typical symptom, but was not constant, and was evidently due to local infection. Radiation along the course of the ureter was present in seven cases in which the calculus was located at the ureteropelvic junction. Other radiations noted were to the opposite kidney region, chest, right lower quadrant, testes, thigh, and entire back. Invariably the larger the calculus, the less severe the pain, and in eight cases only vesical symptoms were present. In four of these cases the kidney had gone on to almost complete destruction. Tenderness in the costovertebral angle or anteriorly in the right upper quadrant was elicited in thirty-two case, and the kidney was palpable in only eighteen. Roentgenograms were positive in all but two of the cases of renal calculi. In these two a diagnosis of an obstruction at the ureteropelvic junction was made, and at operation a calculus was found. The character of the urine was found in sixteen cases to be of no aid in establishing a diagnosis of renal calculus, while in the remaining twenty-seven cases blood and pus cells were found in varying quantities. Profuse hematuria was present in four cases. Colon bacilli were found in thirty-one cases, staphylococci in four. In two bilateral cases the entire renal cavity was filled with phosphatic deposit.

If a calculus does not increase in size too rapidly, it passes from the kidney into the ureter, and in its passage through this channel may give rise to a clear-cut picture of renal colic, or to a greater variety of symptoms than any other abdominal condition.

Of 150 cases of calculi of the upper urinary tract, 107 were ureteral calculi, and while they were found lodged at almost every point, from the ureteropelvic junction to the vesical orifice of the ureter, eighty-six were lodged in the lower 12 centimeters, and sixty-five of these in the last 6 centimeters. The symptoms in these cases extended in duration from a few hours to fifteen years.

The young woman whose condition is next described furnishes a typical case.

Case 2.—A woman, aged 21, twelve hours before admission to the hospital, was seized with a sharp pain in the right lumbar region, accompanied by vomiting and shock. The pain soon radiated to the groin. The following morning the pain was most severe in the right lower quadrant, and there was an urgent desire to urinate. Urine was scanty. Examination of the bladder revealed edema about a functionless right ureteral orifice. A ureteral catheter encountered an obstruction 2 cm. from the bladder. A roentgenogram revealed the catheter in contact with a small shadow. The ureter was dilated and a small calculus removed with ureteral forceps, with complete relief and no return of symptoms.

Case 3.—A woman, aged 44, for fifteen years had had pain in the right side of the abdomen, not localized. She complained of indigestion, constipation, flatulency, painful menstruation, and frequent burning urination. She had had a nephropexy, an appendectomy and a ventral suspension; the right ovary had been removed, the bladder irrigated, and medical treatment given, with no relief. Investigation showed a calculus lodged in the right ureter, at the pelvic brim, with pyelonephritis. Removal of the calculus gave partial relief of symptoms.

Between these two extremes were all types and degrees of abdominal symptoms, but pain was a fairly constant factor in all cases of ureteral calculi.

Eighty-six of the 107 cases of ureteral calculi gave a history of pain on the affected side, 4 of referred pain on the opposite side, 65 had a definite colic, and 45 had had from two to eleven attacks; 35 gave a history of having previously passed calculi.

Of the 65 cases of calculi lodged in the last 6 centimeters of the ureter, 56 complained of urinary symptoms.

Cystoscopic examination revealed the calculus lodged in the mouth of the ureter in 4 cases. Edema about the orifice was present in 47 cases. A deflection of the stream of urine from the ureteral orifice was noted in several cases in which the calculus was lodged in the intramural portion of the ureter. The urine showed pus cells or blood cells in 81 cases;

was normal in 22 cases. Crystals were noted in 18 cases; colon bacilli showed a growth in 62 of 78 cases in which a bacteriologic examination was made.

In 75 per cent. of the cases a definite obstruction, partial or complete, was evidenced by passing ureteral catheters and bougies. In 11 cases the calculus could be located by palpation through the vaginal vault and in four males by rectal palpation.

No roentgenograms were taken of 16 patients who passed calculi subsequent to the cystoscopic manipulation. In the remaining 78 cases a roentgenogram was made with opaque catheters or bougies in position. A positive plate was obtained in 56 cases. The 22 patients not showing a shadow passed calculi following manipulation. These calculi were all small, and were either phosphatic or uric acid stones. A collection of crystals causing a definite colic was present in six cases. A complete obstruction was encountered in each case, and was relieved by intra-ureteral manipulation.

I have made it a practice for the past five years to boil the catheters and bougies, thus rendering the bougie soft enough to pass through almost any kink, or to coil about a calculus. Often the tip of the bougie is bent so that it is hooked, and by passing the bougie, twisting it as it advances, the calculus, which would often otherwise be passed by, is encircled by the bougie. In this manner, with stereoscopic roentgenograms to eliminate extraneous shadows of phleboliths, calcareous glands, atheromatous patches, enteroliths and gallstones, a diagnosis may be made in two thirds of our cases. In the remaining third, a ureterogram, the calculus being coated with collargol, or the employment of wax-tipped catheters, may be necessary, and all methods may be negative.

I have no doubt that in some of our cases which were passed by as negative, with ureters free to a No. 7 F. catheter, with negative urine and roentgenograms, a calculus may have been lodged in a sacculation of the ureter which has since caused symptoms. I am inclined to believe that the wax-tipped catheter should be used more frequently in these negative cases, and it is wise to have all patients report for subsequent examination.

A differential diagnosis between ureteral kinks, urinary tuberculosis, renal tumor, and stone often may be difficult, and may be made only by repeated examinations.

Calculi in the lower ureter may cause symptoms so like appendicitis that it has almost become routine to pass a ureteral catheter in all cases of right-sided pain. Pelvic disease and acute intestinal lesions in connection with calculus in the lower ureter, gallstone colic, acute gastric and intestinal conditions, must be excluded in calculi lodged in the upper ureter and kidney. This should always be possible with the means at hand, although the possibility of the presence of more than one lesion should be borne in mind.

The treatment of calculi of the upper urinary tract can now be laid down on definite principles.

A renal calculus remains in the kidney and increases in size, acting as a menace to the kidney and to the patient, or it passes into the ureter. If it remains in the kidney it should be removed, unless there is contraindication to operation from the condition of the patient, or of the opposite kidney, and the sooner it is removed the better. By its remaining, more or less of the kidney will be ultimately destroyed. When the kidney destruction is advanced, as proved by pyelogram and functional tests, or when many calculi are present throughout the kidney, a nephrectomy may be necessary, as in four of the cases of this series. In cases of large branching calculi the kidney may have to be split, as in two cases. The remaining cases can be relieved by pelviolithotomy.

If the calculus passes into the ureter, and does not enter the bladder after manipulation with ureteral catheters, bougies, and dilatation of the lower ureter, it should be removed. That the majority of ureteral calculi will pass, certainly after manipulation, is proved by this series. Ninety-two of 107 calculi lodged in the ureter were passed subsequent to or removed by cystoscopic manipulation. Only fifteen were removed at operation.

Calculi should not be allowed to remain in the ureter too long. Stricture of the ureter, or damage to the kidney from back pressure and infection, will often be the result. The sooner the patient is seen after the initial attack of colic, the better the chance of assisting the passage of the stone.

While all methods of manipulation and injection have been applied, dilation of the lower ureter and manipulation of the calculus with catheter and bougies, in an attempt to loosen and change the axis, was deemed of advantage. There is no doubt that this is worth repeated attempts. Several calculi have been followed with roentgenograms in their descent after manipulation, showing the advance of the calculus with each attempt. This process has been repeated as many as eight times, but the first few attempts will usually be successful if the calculus is going to pass. An attack of colic is often brought on at the end of the manipulation, and denotes that the calculus has shifted its axis and is obstructing the ureter. Large quantities of water will supply the pressure above, and the stone will be passed.

A method which has proved successful, even in as large a culculus as the one exhibited (3.5 by 1 cm.), is to hook the end of the ureteral bougie and twist the bougie as it is advanced along the ureter, coiling it about the calculus and then applying traction. A calculus was extracted two weeks ago in this manner. This patient had undergone a ureterotomy for a calculus one quarter the size, lodged at the pelvic brim. A fistula resulted which healed only after inserting an indwelling ureteral catheter, which was left in position for ten days. A diverticulum formed at the point at which the calculus had been lodged. Twelve calculi have since formed in this pouch, descended into the lower ureter, and have been extracted with ureteral forceps, or passed after intra-ureteral manipulation.

How large a proportion of these ureteral calculi would have passed had nothing been done, it is impossible to say; but it is probably fair to assume that 50 per cent. would have been recovered. Only six patients giving a history of ureteral colic, negative at examination, returned with a history of subsequent attacks and passing a calculus.

Fifteen of the calculi removed at operation were approached extraperitoneally, and one transperitoneally.

There were two deaths out of the forty-three patients operated on for renal calculi, both caused by uremia, in bilateral phosphatic calculi. The operation in each instance was undertaken against advice. One patient with ureteral calculus died six weeks subsequent to operation. The cause of death could not be ascertained.

In this review of 198 cases of lithiasis, several points are worthy of note with regard to the forty-four cases of vesical calculi. A definite history of renal colic, with relief of pain without passing the calculus, was given in fourteen cases, and in the remaining thirty it was found that the bladder was the seat of an infection and was carrying residual urine. The cause of the retention was prostatic obstruction in the males, and cystocele in the females —a rather convincing argument that infection and urinary stasis play an important rôle in their formation.

The diagnosis of vesical calculus should be simple. Seldom is it impossible to pass a small cystoscope into the bladder and make a diagnosis by sight. A roentgenogram, in the absence of a cystoscopic examination, is often sufficient.

Of the forty-four cases, the calculi were crushed and evacuated in thirty-three, and removed by cystotomy in eleven cases. Litholapaxy is still an important procedure in cases not requiring an operation on the bladder or prostate, and when supplemented by the use of the cystoscopic lithotrite, should be the method of choice more often than it is.

Prostatic calculi, the result of long-standing prostatic infection, were found in three cases. The diagnosis was easily made by palpation. Undoubtedly they are occasionally overlooked, the diagnosis of malignancy being made. More frequent roentgenograms in patients giving prostatic symptoms of long standing might disclose more cases of prostatic calculi. The treatment is by prostatectomy.

One case of calculus in the seminal vesicle was noted, and a renal calculus with a clear history of colic followed by retention showed the calculus lodged in the prostatic urethra. This was dislodged with forceps applied through the endoscopic tube, and was passed by the patient.

RECAPITULATION

Intestinal stasis is an important predisposing factor in the formation of urinary calculi. Urinary stasis and infection are immediate predisposing factors. Renal mobility plays an important rôle in this consideration.

Renal calculi may be single or multiple; small or large; unilateral or bilateral; located in the cortex, the pelvis or a calyx; or they may be branching, completely filling the cavity of the kidney.

Local symptoms may be absent, slight, or acute. Physical signs may be absent or definite. A diagnosis of the presence of a calculus should be made by cystoscopic and roentgenographic methods. Contact of the tip of a roentgen-ray bougie will verify the diagnosis in many cases of renal calculi, but may have to be supplemented by pyelograms, not only to locate exactly the stone in the kidney, but also to show the extent of kidney destruction. Data so obtained make it possible to outline the operative procedure which will result in a cure, and after-care may prevent recurrences.

Ureteral calculi are common. They may give rise to indefinite abdominal symptoms, or to typical colic. Fifty per cent. of ureteral stones will pass; 75 per cent. will be passed following intra-ureteral manipulation, which consists in dislodging the calculus and dilating the ureter below.

Vesical calculi are comparatively rare, owing to earlier diagnosis and the better treatment of vesical obstructions. When found, they are smaller than formerly, owing to the earlier diagnosis, and can often be removed by litholapaxy, unless a prostatectomy is necessary.

Prostatic calculi should be suspected in long-continued prostatic suppuration. They should be diagnosed early and removed by prostatectomy.

40 East Forty-First Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CALDWELL, YOUNG, JR., AND BUGBEE

Dr. Henry K. Pancoast, Philadelphia: After Dr. Caldwell's numerous references to the unquestioned value of the roentgen diagnosis of urinary calculus, all must agree that a roentgenographic study should be made in every case in which calculus is suspected. A careful examination should be made of the entire tract, for the reason that a stone may not be where it is suspected, may be on the side opposite to the symptoms, or there may be calculi on both sides. In the second instance the stone may not be found, and in the third, the patient's life may be endangered by operation if only one kidney or ureter has been examined. Even though a calculus shadow is found only on the side opposite to the symptoms, a small uric acid stone or one hidden by bony structures may be present and missed and be accounting for symptoms.

When one considers the numerous sources of error it is remarkable that the percentage is so small, as Dr. Caldwell has stated. Most of them have already been alluded to in the papers, but a few have not. The most important and most frequent is careless or faulty preparation of the patient. Adequate preparation means the withdrawal of food for nearly twenty-four hours before the examination, complete evacuation of the intestinal tract to eliminate both fecal contents and gas, and the withdrawal of drugs, especially in pill or tablet form. Possibly salol is the worst offender. Of course, foreign bodies in the intestinal tract other than pills form a small percentage of sources of error. Dark moles on the back constitute a well known source. Phleboliths in the pelvic veins are extremely troublesome and cannot always be eliminated even by the ureteral catheter and stereoscopic plates. Calcified mesenteric glands frequently give trouble, especially when near the renal region.

The last essayist mentioned fecaliths, and when these are in an inflamed appendix close to or adherent to the ureteral region they may be misleading clinically and roentgenographically. In one instance a dermoid cyst containing a single tooth and pressing on and obstructing a ureter led us to a diagnosis of a ureteral calculus because of the tooth shadow in the ureteral line. Finally, many stones, especially uric acid calculi, may be hidden by the bony parts or may not be seen in very stout persons.

Dr. W. F. Braasch, Rochester, Minn.: Because of this obscurity of symptomatology the following rules have been made at the Mayo Clinic:

Roentgen-ray examination is made (1) when abdominal pain is not definitely localized; for example, in the gall-bladder, the appendix or the pelvis; (2) when, though the pain is definitely localized in these organs, there is pus or blood or a past history of pus or blood in the urine, and (3) in the absence of abdominal pain, if there is a past history of pus or blood, or if microscopic pus or blood is found in the catheterized specimen.

The leaded catheter is of value in the diagnosis of ureteral calculus only when the calculus is 2 cm. or more away from it and when it is in close apposition and cannot be passed beyond the calculus. When the leaded catheter is in close apposition to a suspected ureteral shadow it is of little diagnostic value. Nor does a stereoscopic examination help much, because, even though the stereoscopic examination reveals that the leaded catheter is a centimeter distant from the shadow, it does not mean that the shadow is extra-ureteral.

In such doubtful cases a more exact method of interpretation is available in the ureterogram. This method should be employed only when others have failed, and when the introduction of the catheter is not obstructed. The use of the ureterogram is restricted because the procedure is not without danger. Any fluid injected beyond an obstruction, whether it be boric acid solution, silver or thorium, will cause damage to the parenchyma of the kidney unless drained out. If an opaque medium is injected beyond an obstructing stone in the ureter, a great deal of trouble will result in a small percentage of cases, so much so that the kidney may have to be sacrificed. Therefore, a ureterogram should usually not be made unless the catheter can be passed beyond the shadow and the injected fluid can be removed. Of the various solutions, thorium is undoubtedly the best, because with careful technic it can be removed. The catheter should be allowed to remain for a few minutes after washing out the renal pelvis.

Pyelography has also proved to be a valuable method in the diagnosis of shadows situated in the renal area. It may be used more freely in the pelvis of the kidney because the fluid is seldom obstructed by a stone. Further, pyelography is of value not alone in the diagnosis of shadows in the kidney, but also in the localization. Those of you who have had experience in searching for a stone in a large, congested kidney will appreciate any effort made by the diagnostician to localize exactly any small shadow in the kidney.

Dr. Herman L. Kretschmer, Chicago: The stereoscopic pictures with shadowgraph catheters are of value in a certain percentage of cases. The stereoscope will show in a certain number of cases a definite interval between the suspicious shadow and the catheter. I agree with Dr. Braasch that in some cases the stereoscope will not help out. In those cases the ureterogram is in perfect order. In the doubtful cases it would be well to use some silver salt instead of the thorium in making the ureterogram. Kümmel in Hamburg first called attention to the fact that shadows were made more positive by silver salts.

Dr. Bugbee's statement, I think, was a little bit too conservative when he said that about 50 per cent. of these stones can be passed or removed by noncutting operations. The percentage is much higher. Probably all of these ureteral stones which have not remained in the ureter so long as to produce a stricture can be worked down or passed by the use of papaverin and oil injections. Thus far I have been rather successful. The idea of Dr. Bugbee of turning the catheter around the stone and pulling it out is rather unique. I wish in closing he would tell us just how he curls the catheter around the stone.

The point has been emphasized several times that the entire urinary tract should be roentgen rayed. Frequently patients have just one part of the urinary tract rayed and they are operated on after a diagnosis made from one picture. I have in mind two patients who had been operated on elsewhere and a kidney removed, and they have calculi now in the remaining kidney. It would be interesting to know whether they had bilateral stones in the first place, or whether the remaining stone has formed in the kidney since operation.

Dr. Abraham Hyman, New York: In a series of seventy-four cases of ureteral and renal calculus we have had 10 per cent. of negative roentgenograms. In vesical calculus more than 61 per cent. of the stones failed to show. A large number of these negative roentgenograms were in prostatics, which probably accounts for this high percentage. In thirty-four of the seventy-four cases of ureteral calculus the ureteral catheter was obstructed at the site of the stone, and in 50 per cent. of these cases there was a considerable difference in the output of indigocarmin; it was either absent or considerably diminished.

As regards the wax tipped catheter, it was of considerable value in but one case. In this patient, a rather stout woman, there were three negative roentgenograms. She had pus in the urine and radiating pain in her side. The wax tipped catheter showed distinct scratch marks on two occasions.

During the past few years three patients have been operated on in the service for renal calculus in which most of the findings were considered positive. The Roentgen ray demonstrated distinct shadows in the renal region. Unfortunately, the symptomatology and the ordinary methods of examination were thought to be so characteristic that other methods, such as pyelography, the wax tipped catheter and stereoscopy, were not employed. At operation there was no calculus to be found in any of the three cases. In two, we could distinctly feel retroperitoneal calcified glands which undoubtedly cast the shadows. In the other case the symptoms were found to be due to a twisted ovarian cyst. This was not discovered until the patient returned to the hospital six months later, complaining of the same symptoms. She was operated on and a twisted ovarian cyst was found.

Concerning urinalysis, we have had a few cases of renal and ureteral calculus in which the urine examination was entirely negative—no pus or red blood cells—so one cannot rely absolutely on negative urinary findings.

Dr. James W. Hunter, Norfolk, Va.: As a roentgenologist I have made about 1,200 examinations. Three cases were most remarkable. A man of 45 whose only complaint was night sweats showed no emaciation and had no cough. An examination of his right kidney showed the most beautiful growth of dumb-bell and mushroom kidney stones that I have ever seen and its removal effected a complete cure. A woman presented all the typical symptoms of kidney colic. The kidney was negative, but at the ureteral orifice was found a shadow typically cigar shaped. Cystoscopic examination and the passage of a bougie showed that the shadows coincided. She was operated on by a prominent surgeon and nothing was found. She was examined about a year afterwards in consultation with another surgeon. The same symptoms and the same shadow were found. On operation nothing whatever was found near the ureteral orifice. The ureter was dilated and inflamed. The cigar-shaped calculus was found in the pelvis of the kidney. When the woman was up and about the calculus would descend to the lower end of the ureter, but when she remained in bed it worked back up to the pelvis. This woman is well now.

Dr. H. A. Fowler, Washington, D. C.: It has been definitely brought out that there are no pathognomonic signs or symptoms of stone in the kidney or ureter. A stone may be present in the kidney without giving rise to any symptoms whatever, either on the part of the kidney or of any other organ.

On the other hand, there may be no signs or symptoms referable to the kidney itself, the seat of the disease, but the symptoms are entirely abdominal, or referred to some abdominal organ. This has been shown by the statistics of Braasch and Cabot particularly.

The demonstration of the presence of a stone in the ureter or the kidney is only the first step in the diagnosis. It is important that the diagnosis should be made complete. That means, first, the location of the stone. Is the stone in the kidney, in the pelvis, in the calices or in the ureter? Is there more than one stone? Is the stone in the upper or lower pole? If we can locate the stone definitely in this way the operative procedure is simplified and the trauma resulting from operative interference is reduced to a minimum. Instead of doing as the general surgeon has been doing in the past, exploring the kidney by making a wide section, if we know where the stone is situated we can make a small incision through the capsule over the stone and extract it through the small incision. This means much less trauma and a much simpler operation.

It has not been my experience to meet with as large as 12 per cent. of cases in which no blood or pus was found on repeated examination of a centrifuged specimen of urine. I was taught to believe that in the majority if not all cases of stone in the kidney or ureter if repeated examination of a centrifuged specimen was made blood would be found, and that has been my experience. I recall only one case, that of a stone in the upper calyx of the kidney, in which repeated examinations failed to show the presence of a few red blood cells. There is no reason to doubt his statistics, but I simply mention my personal experience.

Dr. G. G. Smith, Boston: In regard to Dr. Fowler's point about the presence of blood in the urine, I have lately noticed that in the routine examination of urine specimens from patients in the women's genito-urinary outpatient clinic at the Massachusetts General Hospital we have had an almost constant report of a few red blood cells, and that has happened so often that it has made me feel that in a thoroughly centrifuged specimen examined by a conscientious, thorough house officer a few red blood cells will almost always be found. I should like to hear some opinions on that. Some of these patients whose urine showed the red blood cells certainly had nothing wrong with the genito-urinary tract that we could discover in any other way, and there were too many of those cases showing red blood cells and nothing else for one to say there was a stone which could not be detected.

I have injected papaverin into the ureter once in each of four cases of ureteral calculi. In two cases the calculi were passed two weeks after the injection. The other two patients, the last time I saw them, had not passed their stones.

Dr. A. M. Wose, Syracuse, N. Y.: Recently six exposures of a calculus in the bladder were made, with negative findings. Examination with the cystoscope readily showed the calculus. This caused a little controversy with the roentgenologist, and in order to appease him I suggested after the extraction of the stone that I would be glad to make a little investigation with this calculus on a plate with the electrode at a distance of 18 inches. He did that, with negative findings. After that I suggested that he take a picture of his hand with the calculus on the hand, with the electrode 18 inches above, which he did, and there was no shadow of the calculus. Then I said the investigation ought to be chemical. It proved to be a pure uric acid stone.

Dr. V. D. Lespinasse, Chicago: In this connection I should like to report some work that has a bearing along this line. I started out to determine the changes that occur in the kidney following obstruction from a stone. I found that complete obstruction caused very rapid and severe changes. When the obstruction was partial the changes came on slowly and involved the ureter primarily. From that it was changed over to a clinical problem. By introducing a little stick of wood it was found that we could obtain a dilatation of the ureter, beginning at the lower end, and as time went on, going up to the kidney and ultimately involving the kidney; but it takes from ten to twenty days before any change occurs in the pelvis of the kidney. In that time there will be a dilatation of the ureter to about two to three times its normal diameter. Then after this work was done on the animals it was changed over and this little plug was adapted so that it could be introduced through the cystoscope and applied at the clinic. The plug was made from a small piece of laminaria with an opening through it. Inserted through the cystoscope and left in place, the plug swells. The opening in the plug also swells, so that if it is a No. 6 when it goes in, in an hour or two it swells to a No. 15, varying somewhat. The urine trickles through the hole and the ureter begins to dilate above the plug. The procedure is painless. Our clinical experience with it so far has been limited to one case in which there was a stone about a third of the way down the ureter and two stones in the kidney. We put the plug in place and left it there for a day, and the day following the man passed his stone. Then we sent him out to ride the roads in a well known automobile which the doctors commonly use and he shook the two stones into his ureter. He came back and we put the plug in his ureter again and he passed the two stones.

Dr. B. S. Barringer, New York: I should like to report just one unusual pyelogram result which misled us a great deal. The patient came to the Bellevue Hospital with symptoms of stone. A roentgenogram was made and a nest of three or four stones was found just above the crest of the ilium. We cystoscoped him and found an inflamed bladder and two ureters, and we injected thorium into the suspected kidney pelvis, with the result that we had a beautifully dilated pelvis up under the ribs. The thorium was plainly outlined, and the nest of stones down about 3 inches from this dilated kidney pelvis with no connection between the two. We thought he had double ureters and a double renal pelvis and that we had missed one of the ureters on cystoscopy. At the operation we looked for two ureters but did not find them. We found a large, dilated pelvis with a stone at the lower end. The thorium probably had not had time enough to diffuse through the entire pelvis.

Dr. J. E. Burns, Baltimore: About 30 per cent. of the calculi are missed in the plain roentgenogram. I have already called attention to the fact in several publications that the ureteral calculi missed in the plain roentgenograms are brought out by the thorium solution, either by the adhesive qualities of the solution or by its comparative density, or by the fact that the thorium solution is absorbed by the calculi. We have used this solution since its introduction in the Brady Clinic about two years ago in, I suppose, 400 cases. We have seen no ill results in any case. None of the cases have shown any necrosis or any destruction of renal parenchyma due to retention, which latter occurs very rarely, if at all.

It is essential that the solution be allowed to flow in while the roentgenogram is being made, so that the pelvis and ureter may be fully dilated. On repetition of the roentgenogram in such cases it might be well, in order to insure complete distention of the pelvis, to lower the head of the table and allow the solution to flow in by gravity. If the first attempt is not good, and if the ureterogram is not clear in the lower portion, the position, of course, should be reversed, and it will be found in practically every instance that the ureteropyelogram will be satisfactory.

Another important thing in the diagnosis of ureteral calculus is to employ the wax-tipped catheter. This, together with the pyelogram and the plain roentgenogram, is employed as a routine measure in the Brady Clinic.

Dr. A. J. Crowell, Charlotte, N. C.: I do not believe the presence of blood in a centrifugalized specimen of urine obtained by ureteral catheter means as much as some would seem to think. It is difficult, yes, almost impossible, I believe, to get urine with the ureteral catheter without getting some blood in a centrifugalized specimen of urine thus obtained. The presence of pus, of course, is a different thing. Personally I do not lay much stress on the presence of blood, but the presence of pus is very significant.

Just a little off the subject, and yet brought out by Dr. Bugbee in his paper, is the removal of stone from the ureter by the use of the ureteral catheter. About three years ago while endeavoring to remove a recently impacted stone from the ureter it occurred to me that it would be common sense to inject cocain or novocain into the ureter to deaden the sensation and thus allow the ureter to relax and assist the stone to pass out. This procedure was carried out and the next day the stone was found in the patient's bladder. Of course, this stone may have passed if nothing had been done, but it encouraged trying the plan in other cases. Since that time I have had twenty-three or twenty-four cases and have had to operate on only two patients for the removal of ureteral stone. I am convinced now that if I had persisted then (that was in the beginning of this work) as I do now I would have removed those two. It may take a number of treatments to remove stones in this way, but I believe that every recently impacted ureteral stone can be removed in this way if we get at it in time. I removed three from one ureter but it required six or eight treatments. If we will only persist in our efforts with the cystoscope and some form of local anesthesia, I believe we will seldom fail to remove these stones.

Dr. C. M. Harpster, Toledo, Ohio: I wish to endorse the position taken by Dr. Smith and Dr. Fowler. I believe if we make careful investigations of the urine we will, with the possible exception of a few cases, find microscopic blood. I think this is our most important diagnostic point clinically. The possible exception is in those cases in which there has been an occlusion of the ureter from impaction of the stone in the ureter or in the pelvis of the kidney; and in those cases in which there has been complete exclusion of the ureter, of course, we would not find microscopic blood; but in my experience I have, in a large number of cases, found microscopic blood after painstaking investigation.

Another point is in regard to reflex anuria which follows cases in which there is a single impacted stone *on one side*. It has been my experience in those cases in which there is anuria lasting three, five, and, in one case, ten days, that we will, on careful and repeated roentgen-ray examinations, find an impacted stone on the other side. In every case in which there have been bilateral calculi reflex anuria has not been found present. In those cases, I believe, we should make repeated searches to locate the stone *on the other side*. One of my old preceptors, Professor Israel, laid particular stress on this point, and in two cases I believe we were able to save the patients' lives. Where there *is* complete anuria differentiated from nephritis, in nephritis we will at least have a teaspoonful of urine excreted; that is, we will not have in any *nephritic* condition a complete and absolute anuria; and so by remembering this point I was able, in two cases of ureteral calculus in which experts had made a diagnosis of nephritis with complete suppression of urine, to find bilateral ureteral calculi.

Dr. Edward L. Young, Jr., Boston: Dr. Bugbee's trick of coiling a ureter catheter around a stone is a very pretty trick and a great help, provided it comes out all right. One case in connection with it might perhaps serve as a warning in the use of the procedure — a case in which a ureteral stone was hooked in that fashion, but then the fisherman was not able to bring in the fish, and for over an hour tried to get the catheter out. So I think there is a warning in regard to the use of the ureter in that condition, on account of the possibility of breaking off the catheter and also of getting the catheter up and having it caught there.

I wanted to emphasize what has been already emphasized, the indefiniteness of symptoms in the majority of cases of renal stone. Also, typical symptoms do appear, including blood and pus, without any calculus being present, and especially the symptom of pain. I think all statistics of pain in connection with calculus show that it is almost always indefinite and often misleading.

I have not looked up the cases at the Massachusetts General Hospital in regard to crossed symptoms, but I can *only* remember having seen two cases within a comparatively recent time, and I should like to register my opinion that a damaged kidney on one side without any symptoms, and a normal kidney on the other which seems to have the symptoms, is a comparatively rare condition. I do not mean that symptoms may not be mainly on the undamaged or slightly damaged side, but I think a normal kidney on one side showing symptoms and a damaged kidney on the other not showing any symptoms is, at least in my experience, rare.

Then the question of the removal of ureteral stones without operative procedure which has been *spoken of* so enthusiastically by every *one* today—I do not know whether we in Boston are slower than the rest of you in making a diagnosis, or less skilful in the use of the operating cystoscope, but we see large ureteral stones *that* I am *convinced* it would be impossible to remove by any method short of the open operation. Likewise, we fail to get stones of moderate size out in a percentage of cases larger than that spoken of today.

SPINAL PUNCTURE IN DIABETES INSIPIDUS

EVARTS A. GRAHAM, M.D.
Fellow of the American College of Surgeons; Surgeon, Park Hospital
MASON CITY, IOWA

Since the discovery by Magnus and Schaefer[1] in 1901 of the diuretic action of extracts of the posterior lobe of the hypophysis, attention has been directed to that organ as an important factor in the causation of diabetes insipidus. Frank,[2] in an important article published in 1912, reviewed the literature then existing on the subject and made a strong plea for a consideration of the relationship between the hypophysis and diabetes insipidus. Numerous writers already had emphasized the fact that lesions of the brain which involved the vicinity of the hypophysis were often accompanied by polyuria without sugar. Oppenheim,[3] in thirty-six cases of basal syphilitic meningitis, observed polyuria in twelve. Two of these showed at necropsy a gumma of the optic chiasm and hypophysis. Kruse,[3] in a study of thirty cases of bitemporal hemianopsia, observed diabetes insipidus in seven; and Spanbock and Steinhaus[3] mention its occurrence in eleven of fifty cases of bitemporal hemianopsia. Polyuria associated with metastatic carcinoma involving the hypophysis or its region, secondary to carcinoma of the breast, is a fairly frequent occurrence. Cases have been reported by Simmonds,[4] Rosenhaupt,[5] Miller[6] and von Gierke.[7] Recently Sekiguchi[8] has described two additional cases. Cushing's experiments in 1913 led him to conclude that there was a strong "argument in favor of the view that an actual disturbance of the pituitary body itself, rather than the stimulation of some predicated diuretic center in the remote third ventricle surmounting the growth, was the inciting cause of a condition worthy of the designation of diabetes insipidus." Lewis and Matthews[10] in 1913 concluded from their experiments that diabetes

insipidus is probably dependent on the hypersecretion of the diuretic substance of the posterior lobe which is secreted by the epithelial covering known as the pars intermedia. Falta,[11] however, warns against a too hasty conclusion that lesions of the base of the brain which induce polyuria do so always by mediation of the hypophysis, although he discusses at length the possibility that such may be the case.

Several cases of diabetes insipidus of which the onset occurred after a trauma to the head are in the literature. Doubtless, at least a temporary polyuria will be found to be very common after head injuries, especially basal skull fractures, if attention is more frequently directed to the output of urine. Mohr[12] has recorded a case which developed about three weeks after a basal skull fracture, and Kleeblatt[13] has described one occurring on the third day after a similar lesion. French and Ticehurst[14] also observed a case of diabetes insipidus which had its origin in a fracture (through the sphenoid). Recently I have seen a case of fracture of the skull in which the roentgenogram clearly revealed the line of fracture extending into the sella turcica (Fig. 3). During the first twenty-four hours the amount of urine passed was 40 ounces (1,280 c.c.). During the second day the total amount increased to 130 ounces (4,160 c.c.), and on the third day 110 ounces (3,520 c.c.) were passed. Two days later the total output had returned to normal. At no time did the urine show any abnormal constituent. I[15] have recently reported another case in which a total output of 170 ounces (5,500 c.c.) was passed during a twenty-four hour period, following a gunshot wound of the head which severed the optic nerves, probably at the chiasm, with probable resultant injury to the hypophysis. This urine was of a specific gravity of only 1.002, and contained no sugar.

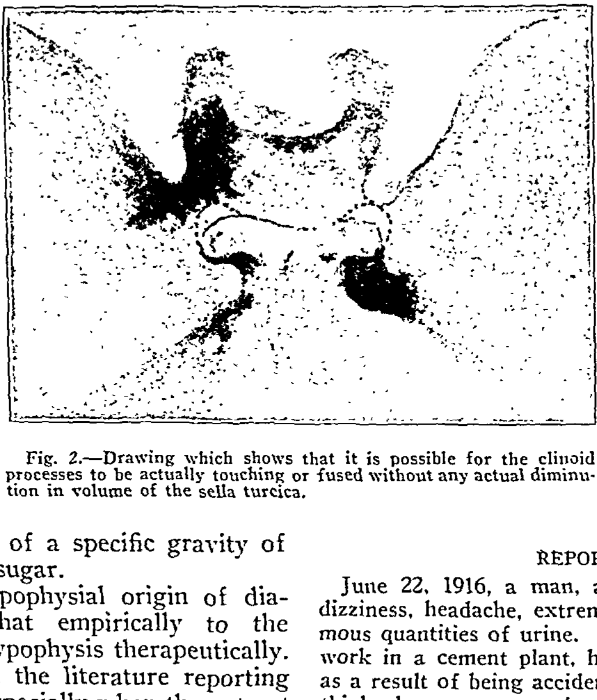

Fig. 2.—Drawing which shows that it is possible for the clinoid processes to be actually touching or fused without any actual diminution in volume of the sella turcica.

The suggestion of the hypophysial origin of diabetes insipidus led somewhat empirically to the employment of extracts of hypophysis therapeutically. Numerous cases are now in the literature reporting markedly beneficial results, especially when the extract has been given intravenously and also even when given hypodermically. Recently Hoppe-Seyler[16] has reported a case of a man, aged 25, with diabetes insipidus who had no evidence of syphilis and no roentgen evidence of any lesion of the hypophysis. Hypodermic injections of hypophysis extract, however, resulted in the restoration of the amount and concentration of the urine to normal. When given by the mouth, no appreciable effect was noticeable. The administration of atropin diminished the volume of urine, but also kept back the solids, whereas with hypophysis extract the solids appeared in normal concentration despite the marked reduction in volume. He considers that the therapeutic results are as striking as those obtained in the treatment of myxedema with thyroid extract. Konschegg and Schuster[17] have also reported an instructive case in which the administration of hypophysis extract to a patient with diabetes insipidus resulted in a return of the urinary conditions and of the water intake to normal. They report that the findings here are in contrast to those obtained when the extract is administered to normal individuals. With the latter, following the injection the decrease in the excretion of water is accompanied by a decrease in the concentration of the solids.

The case reported below is of great interest, not only because it illustrates a type of diabetes insipidus probably induced by disturbance of the hypophysis through an increased pressure of cerebrospinal fluid, but also because *the relief of pressure by spinal puncture was immediately followed by a cessation of the polyuria and other symptoms.* So far as I have been able to learn from the literature, there has been only one other case of diabetes insipidus in which spinal puncture was made. That was a case reported by J. B. Herrick[18] in 1912. In that case the lumbar puncture was made simply for the purpose of obtaining some spinal fluid and with no idea of improving the symptoms; but following the puncture, the amount of urine dropped from 10 liters to 1 liter, and the specific gravity correspondingly changed from 1.001 to 1.031.

REPORT OF CASE

June 22, 1916, a man, aged 24, consulted me because of dizziness, headache, extreme thirst and the passing of enormous quantities of urine. He stated that, March 13, while at work in a cement plant, he sustained an injury to his chest as a result of being accidentally struck with an iron bar. He thinks he was unconscious for a few minutes, although he knows of no injury to the head. He stopped work and went home, but was not compelled to go to bed. A physician told him that he had a fracture of the sternum and of two ribs on the left side. He reported for work on the next evening, but was sent home again and remained away from his work until April 4. Within a day or two after the injury he noticed that he was markedly constipated so that he could hardly get a bowel movement even with cathartics. He had no headache nor dizziness until after he resumed work. Then during the first week of April, he began to notice severe headache and dizziness every day. These symptoms became progressively worse. The headache was chiefly frontal and in the temporal regions, and also sometimes "behind the eyes." It was described as resembling sharp, cutting pains, sometimes going up through the ears. Headache was always worse after excitement or hard muscular work. It was not always present all day. Nausea and vomiting were rarely present, but when nausea did occur, it was always worse at breakfast time. Reading always aggravated the dizziness. No disturbance in power of vision had been noted. The only relief possible from the headache and dizziness was in lying down.

[18] Herrick, J. B.: Report of a Case of Diabetes Insipidus with Marked Reduction in the Amount of Urine Following Lumbar Puncture, Arch. Int. Med., July, 1912, p. 1.

Beginning with the latter part of April, marked polyuria set in. This became progressively worse up to the time I first saw him. During this time he had to get up at night to urinate, frequently as often as six times. During the day he passed urine as often as every hour or half hour. At each act of urination he passed enormous quantities of urine, without pain or burning. He never measured accurately the amount of urine passed in twenty-four hours, but he estimated it as high as 10 or 12 quarts daily. During a period of a little more than an hour while I was examining him, he passed more than a quart. His thirst was insatiable, but his appetite was poor. It was not accompanied by a craving for any special kind of food, such as carbohydrates. He thinks he lost about 25 pounds after his injury.

His previous history was negative except for measles in childhood. He denied any venereal infection. He is the father of a healthy child 1 month old. His family history likewise was of no special importance. His father and mother were both alive and well, the father at 70 years, and the mother at 66. He is one of nine brothers and sisters, all of whom are well.

The examination revealed a fairly well nourished young man who seemed bright and intelligent. Physical examination showed no abnormality of any kind. His vision and eyegrounds were examined by Dr. F. G. Murphy, who reported no abnormality. The blood was practically normal, and the systolic pressure was 120 mm. The urine was clear, slightly acid and of a light straw color. Its specific gravity was 1.001. It contained no albumin or sugar, and practically no sediment except an occasional urate crystal and an epithelial cell. A roentgen examination of the skull revealed a very marked narrowing of the upper margin of the sella turcica (Fig. 1). The distance between the anterior and posterior clinoid processes was only about 2 mm., whereas the normal should be from 10 to 14 mm. He was advised to enter the hospital for several days for examination, but he declined to do so. I then advised that he come to the hospital on the following day for a lumbar puncture and to remain for a few days later. He consented to do so; and on the following day, June 24, lumbar puncture was performed with novocain anesthesia. Immediately after the insertion of the needle into the spinal canal, fluid shot out in a steady stream for a distance of from 8 to 12 inches. Because of the sudden surprising gush, some of the fluid was lost; but a little more than half an ounce was saved. The fluid was still running in a steady stream; but because of fear of too suddenly lowering the intraspinal pressure, the needle was withdrawn. He immediately stated that his headache and dizziness were entirely gone, despite the fact that they had been pronounced before the puncture was made. He was then put to bed; but about four hours later without our knowledge or consent he got up, dressed himself, and walked home, a distance of about a mile from the hospital. On examination the fluid was found to be clear and of a pale straw color. After it was centrifuged, the sediment was found to contain only two cells (mononuclear in type) and no bacteria. It was intended to save some of the fluid for a Wassermann test, but through a mistake in directions it was thrown away. A Wassermann test of the blood, however, was negative.

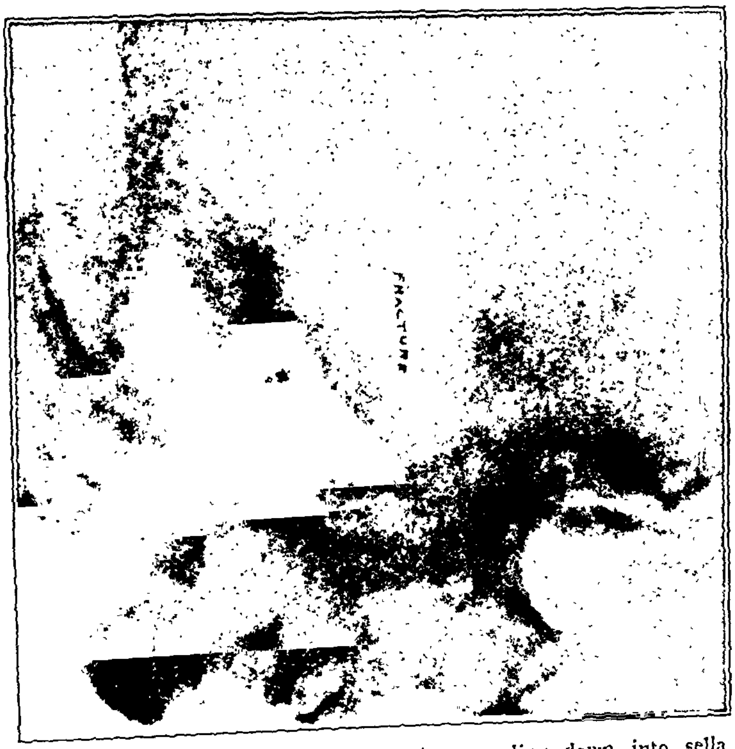

Fig. 3.—Fracture of skull apparently extending down into sella turcica, and accompanied by marked polyuria.

Because of the brief stay in the hospital it was impossible to make any quantitative studies of the urine; but it is interesting that during the four hours in the hospital no urine passed, the longest interval without urination since the onset of the symptoms. The subsequent history is of great interest. For the next four days after leaving the hospital he suffered with intense headache and dizziness to such an extent that he was bedridden, but the polyuria and thirst remained absent. He passed urine at this time only four or five times within the twenty-four hours. He then returned to the hospital and stayed for five days. During this time the headache and the dizziness gradually disappeared. The volume of urine passed during the twenty-four hours varied between 1 and 2 liters, and its specific gravity varied between 1.020 and 1.028. At no time did it show any abnormal constituent.

September 18, we saw the patient again. He stated then that he had been working since the middle of July. He thought he drank a normal quantity of water and passed a normal quantity of urine. Since the spinal puncture he had not had to urinate once during the night; and during the day he passed urine only three or four times. He had gained 5 pounds since leaving the hospital, but still felt dizzy at times. He stated that in the morning he felt perfectly well, but about the middle of the afternoon began to develop a little headache and dizziness, which continued until his evening meal. Then he would feel well again. He attributed the onset of headache and dizziness chiefly to exhaustion from work.

COMMENT

The apparent chain of events in this case is probably as follows: In some unknown way the accident led to an increase in the amount of intraspinal fluid. This in turn led to symptoms suggestive of intracranial pressure, such as headache and dizziness; and the hypophysis was so affected that polyuria without sugar was induced. The immediate improvement of all the symptoms after the lumbar puncture is striking. The question of how the spinal fluid became so much increased cannot be satisfactorily answered. The roentgen-ray findings are interesting, but probably should not be taken as conclusive evidence that the sella turcica was narrowed to the extent of producing pressure on the hypophysis. Although the normal distance between the anterior and posterior clinoid processes varies between 10 and 14 mm., it is possible for the processes to be actually fused without any appreciable change in the volume of the sella and without any symptoms of pressure, as repeatedly verified at necropsy. Figure 2 shows how, owing to the roughly hexagonal form of the sella turcica in the horizontal plane, the clinoid processes may be actually fused without producing any diminution in volume of the sella. The case here reported tends to support the view of the relationship existing between disturbances of the hypophysis and diabetes insipidus.

An immediate striking relief of symptoms has been obtained by the performance of spinal puncture.

ANAL AND RECTAL FISTULA *

J. RAWSON PENNINGTON, M.D.
CHICAGO

In a preliminary report[1] before the American Proctologic Society, at the Detroit meeting, June, 1916, on "Anatomic and Bacteriologic Findings of the Ano-Rectal Region," I called attention to the sinuses and diverticula in this region. It was announced that cocci, and other forms of bacteria, had been found in their walls and contents, and the possible relation to focal infections was pointed out. Since I desire to emphasize the relations between these sinuses and diverticula, and anal and rectual fistula, the present communication is necessarily elementary and textbook-like in character.

A fistula is an infected artificial channel between the skin and the serous or mucous membrane of a normal cavity, or between two normal cavities. It has two or more openings. A sinus, often confounded with a fistula, is an infected artificial channel connecting the skin or mucous membrane with an abnormal cavity. It has, as a rule, one opening only.

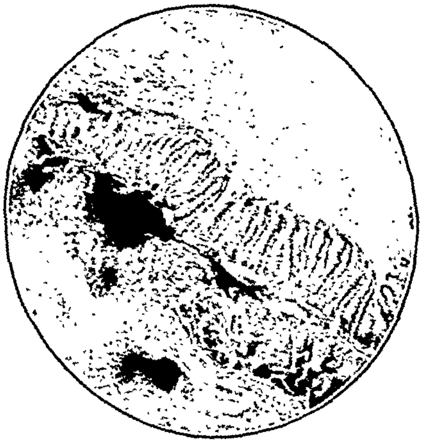

Fig. 1.—Photomicrograph of an infected rectal sinus. The infection has broken through the sinus wall and extended into the surrounding tissues. Compare Fig. 2.

ETIOLOGIC FACTORS

The principal causes of fistula are predisposing (embryologic, traumatic, etc.), and exciting (bacteriologic) conditions.

Embryologic Causes.—The sinuses and diverticula to which I have just referred come under this classification. These sinuses I first noticed many years ago when investigating the structure of the rectal valves, and I referred to them in a paper in THE JOURNAL as "epithelial glands."[2] Later, I frequently noticed the apertures of the sinuses and diverticula during the course of various operations on the lower bowel, and pointed them out to my classes from time to time.

Not long ago, in a patient with hemorrhoids, one aperture was so prominent that a probe was inserted into the lumen for considerable distance. This aroused renewed interest in the subject. Specimens were collected, given to the Medical Research Laboratory of Chicago, and investigations commenced from embryologic, bacteriologic and histologic standpoints.

When the literature was looked up it was a great surprise to find that these sinuses[3] and diverticula had been described by Hermann and Desfosses nearly forty years ago. Some years later they are alluded to in Quénu and Hartmann's book on "Surgery of the Rectum." Since then they have been ignored by all textbooks on diseases of the rectum and those on medicine and surgery. The only reference I have been able to discover of late years is in an article by Johnson.[4]

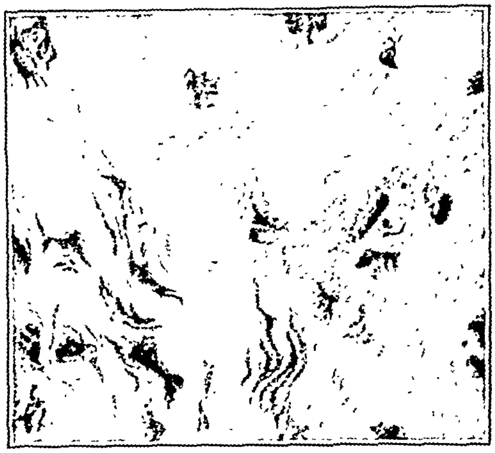

Fig. 2.—Microscopic drawing of a field in Figure 1. It contains colon bacilli, staphylococci and other micro-organisms.

It is not clear why they have been ignored, unless it is because they have had no pathologic possibilities attributed to them. Yet, as will be seen by Figures 1 and 2, and by clinical experience, they are an exceedingly important factor in disease processes in the rectum itself, primarily, and in constitutional conditions, secondarily.

That an important anatomic fact could, in this scientific age, be disregarded or lost sight of for many years, after being placed on record, and then, without knowledge of its former discovery, be rediscovered and found to be of great importance as a disease-producing factor, is almost unbelievable. However, this anatomic finding, when resurrected, proves to be a vital etiologic factor in the causation of fistula and

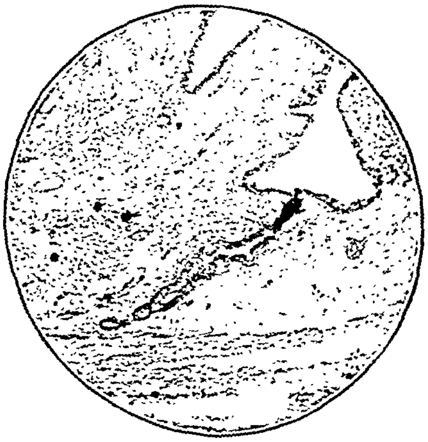

Fig. 3.—Photomicrograph of a normal rectal sinus in a child 1 day old. The wide mouth of the sinus opening into the rectum should be noted. This sinus extends through the mucosa and submucosa to the circular muscle fibers. In some instances they terminate in mucous glands.

other diseases of the rectum, with their metastatic sequelae.

Traumatic Causes.—In this group is included any mechanical injury leading to the formation of a fistula, or that perforates the rectum, connecting it at once with the skin by means of an artificial channel.

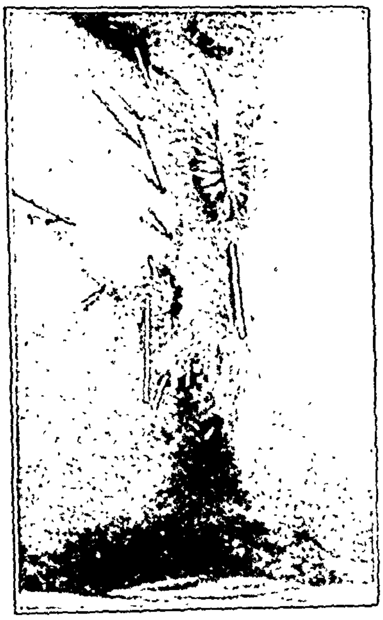

Fig. 4.—This sketch is from Ball's book on "Diseases of the Rectum." It shows one internal and numerous external fistulous openings, and doubtless is intended to suggest the formidableness of a fistula. Yet, the gravity of a case, all things being equal, depends much more on the position of the internal than the number of external openings.

Other Pathologic Conditions.—In this list of conditions I refer to proctitis, cryptitis, constipation, hemorrhoids, fissure, stricture, ulceration and other rectal conditions, which favor the invasion of the sinuses and diverticula and perirectal tissues with pyogenic organisms (Figs. 1 and 2). Such conditions constitute a prefistula stage or period, and aid and abet in the development of the infection stage of fistula.

Exciting Cause.—It has been definitely proved that bacteria are the exciting cause of fistula. The rectal sinuses and diverticula serve as catch-basins or traps for the bacteria (Fig. 3). Here they give off toxins, which aid in producing irritation, to be followed by congestion, inflammation and their escape into the surrounding structures, where they are either encapsulated or lead to an abscess.

Should they produce an abscess, it will continue to enlarge, and the pus to burrow in the direction of least resistance until it finally makes its way through the skin or mucous membrane, forming an internal or external rectal sinus; or, by way of the skin and mucous membrane simultaneously, which forms an infected artificial communication between the skin and a normal cavity, as the rectum or other viscus. Such a channel is known as a fistula.

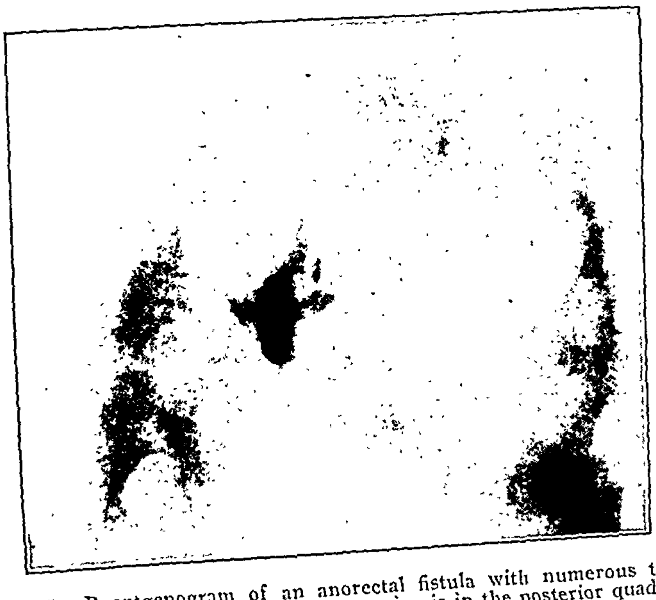

Fig. 5.—Roentgenogram of an anorectal fistula with numerous tracts and external openings. The internal opening is in the posterior quadrant. The patient had been operated on three times by different surgeons. Necrosis of the sacrum, which had been overlooked, was the primary cause.

STAGES IN THE DEVELOPMENT

There are four stages of development, namely, (1) the prefistula stage; (2) the stage of infection; (3) the abscess stage, and (4) the fistula stage.

1. The prefistula stage antedates the stage of the infection, which leads directly to the formation of a sinus or a fistula. A careful examination will show that a very large percentage of fistulas, if not all, are secondary diseases, and that they are preceded in their development by other rectal diseases. From the standpoint of treatment, this is the most important period.

2. The infection stage begins with the invasion of the tissues by pyogenic organisms (Figs. 1 and 2), and continues until the formation of an abscess is inevitable. Authorities tell us that a fistula is due to an abscess; they also state that an abscess is caused by bacteria. Then, is not infection the cause of the fistula, and the abscess one of the stages in its development?

3. The abscess stage commences when suppuration is inevitable, and ends when the pus begins to discharge. It matters not whether this discharge is brought about by ruputre of the tissues or otherwise. The location of the abscess depends on the position of the atrium of invasion; to what point the sinuses or diverticula and the lymphatics lead; the relation of the fascial planes, and the nature of the infection.

Fig. 6.—Roentgenogram of an abscess occurring in the superior pelvirectal space, taken on the third day after it had been opened. It was cured with injections of bismuth paste. *No* fistula followed.

4. The fistula stage begins with the discharge of pus, and ends when the fistula is cured.

CLASSIFICATION

Custom and usage have divided fistulas[5] into two principal varieties, namely, complete and incomplete. The incomplete variety is still further subdivided into blind internal and blind external fistulas, neither of which, however, according to the foregoing definition, is a fistula. Each in reality is a sinus, one an internal and the other an external rectal sinus. Complete or true fistula should be classified, according to the anatomic location of the internal opening, into anal fistula, or fistula-in-ano (the internal opening being located in the anus); ano rectal fistula (with the internal opening located in the junction between the rectum and anus); and rectal fistula (when the internal opening is in the rectum proper). Complex, watering-pot, multiple, horseshoe, and other so-called varieties of fistula are simply expressions of complexity, multiplicity, position or shape of one or the other of the foregoing divisions, or a combination of them.

---

[5] Pennington, J. Rawson: Rectal Fistula, New York Med. Jour., Oct. 16, 1915.

GRAVITY

The gravity of the case, all things being equal, is governed by the position of the internal opening. A rectal fistula with a single tract, and with one opening in the rectum is much more formidable than an anal fistula of the horseshoe or some other variety, with two or more openings in the anus and twenty-five, forty, fifty, or more openings on the buttocks (Fig. 4). The number of external openings has but little to do with the relative gravity of the case.

DIAGNOSIS

The diagnosis of an external rectal sinus—"blind external fistula"—is usually made when an internal opening cannot be demonstrated either by a probe or by injecting water, a solution of methylene blue, peroxid of hydrogen, or other substances, through it and into the bowel. These tests, however, are not infallible. Angulation of the tract may prevent the probe from entering the bowel, while necrotic tissues, or a kind of "trap-door" arrangement along the fistulous channel, may prevent the injection from passing through the channel. The roentgen ray in combination with subnitrate of bismuth ointment, is a valuable aid in the diagnosis of fistula (Fig. 5).

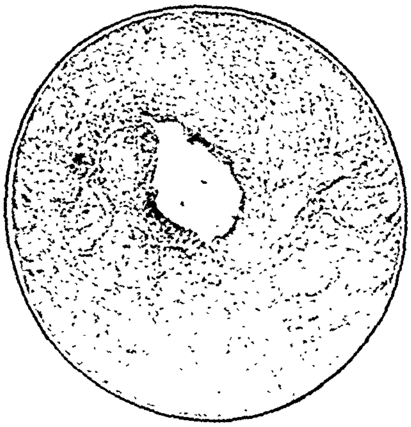

Fig. 7.—Photomicrograph of a cross section of a fistula and its pyogenic membrane. It reveals numerous sinuses extending off from the main tract, and shows why incising the fistulous tract and making Salmon's back-cut so often fail to cure.

TREATMENT

This is preventive (prophylactic and abortive), curative (injections, incision, ligature and excision with immediate suture) and palliative.

Prophylactic.—A careful examination usually elicits the fact that practically every person who has fistula has, or has had, some other form of rectal disease. These conditions favor the invasion of the perirectal tissues by micro-organisms, which may be followed by an abscess and a fistula. If persons were instructed how to keep the rectum clean and in a sanitary and healthy state, and did so, fistula would become much less frequent. Since the number of cases of fistula may be greatly reduced by instruction and preventive medicine, is it not our duty as proctologists to launch a campaign for the prevention of this stubborn affection?

Abortive Treatment.—The time to abort a fistula is during the abscess stage. If the abscess is opened early and the abscess wall not interfered with in any way by means of instruments or drugs, but the cavity freely drained and gently filled with subnitrate of bismuth ointment, and this treatment repeated when indicated, the fistula will, as a rule, be aborted (Fig. 6). Do not forget that too much interference with an abscess has caused many a fistula.

Injections.—I have had most excellent results in the treatment of some cases of fistula by first cleansing the tracts with neutral solution of chlorinated soda, and then injecting them with subnitrate of bismuth ointment.

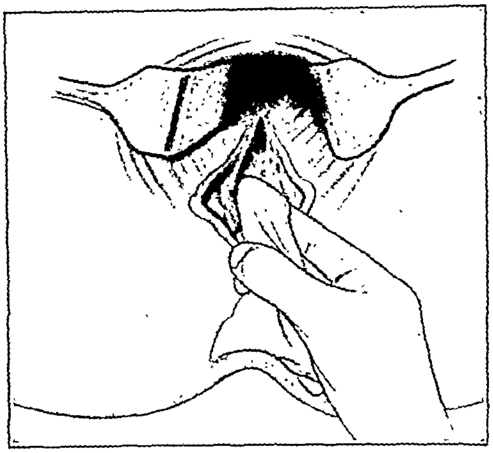

Fig. 8.—Schematic illustration of a fistula incised and the rectum held widely open with retractors. The necrotic tissue is being removed with a piece of gauze, and sinus openings may be seen in the pyogenic membrane.

Incision.—Passing a grooved director through and simply incising the fistulous tract or tracts and the tissues distal to it, and allowing the wound to heal by granulation has been and still is almost universally employed in the treatment of this disease. Tuttle,[6] however, says that "In 2,196 cases operated on in general hospitals by surgeons, less than 45 per cent. of them were even claimed to have been cured." As he failed to state the technic employed, is it not reasonable to suppose that at least 95 per cent. of them were operated on by the incision method either with or without Salmon's back-cut, and that crevices or sinuses similar to those shown in Figures 7, 8 and 9 were not discovered and removed, and that they continued to reinfect the operated field? We believe this to be the reason because: (1) it is the method employed by nearly all operators, and (2) simply slitting up a fistulous tract and not removing the "pyogenic membrane," when it can be done, is certainly not good

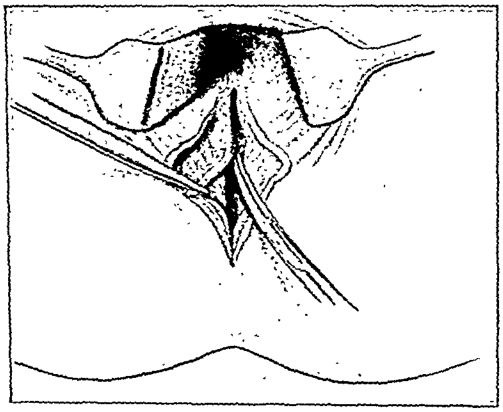

Fig. 9.—Schematic illustration of removal of the pyogenic membrane after the fistula has been incised.

---

6. Tuttle: Diseases of the Rectum.

surgery. Moreover, such procedures necessarily prolong the time of recovery and increase the amount of scar tissue, which may lead to malignancy. Such a case recently came under my care.

Excision with Immediate Suture.—A blunt-pointed director is passed through the fistula and into the rectum. The end in the rectum may or may not be hooked out through the anus. Then, either the tissues resting on the instrument are cut through and the so-called "pyogenic membrane" dissected out (Fig. 9), or the mebrane is dissected out, leaving it threaded on the director. The probe should be used with the utmost gentleness, or a false passage may be made, defeating the purpose of the operation. After the incision of the intervening tissues and the removal of the "pyogenic membrane," care should be taken to locate and remove any offshoots or side channels, since all infected tissue must be removed and the wound disinfected before closing.

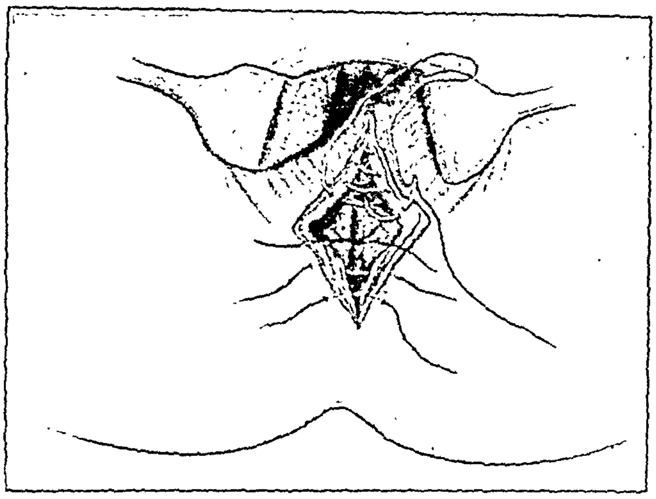

Fig. 10.—Schematic illustration showing the method of closing the mucous membrane, the sphincter and the deeper tissues, and the skin.

Closing the Wound.—Care should be taken that all bleeding is controlled before the wound is closed, otherwise a hematoma may form and prolong, if not defeat the benefits of the operation. Suturing the wound is sometimes very difficult to accomplish. First, I usually close the incision in the mucous membrane, from its termination within the rectum to the skin, with continuous catgut suture (Fig. 10), then the severed sphincter or sphincters and the deeper tissues with interrupted buried catgut sutures (Fig. 10). Finally, the skin and fascia are united with interrupted silkworm gut (Figs. 10 and 11). After the wound is closed, one should attempt no such stunts as pulling the mucous membrane down over the wound and stitching it to the skin, or covering the lines of suturing with collodion dressings, as advised in some textbooks. The wound should be dressed with iodoform or plain gauze and a T bandage applied. I usually direct that the bowels be moved at the end of the third or fourth day with an injection consisting of about 1½ pints of water, in which from 30 to 40 grains of inspissated ox-gall have been dissolved.

31 North State Street.

ABSTRACT OF DISCUSSION

Dr. William M. Beach, Pittsburgh: The history of fistula is one of infection. Very seldom does the proctologist see the acute stage of fistula; that period is usually managed rather indifferently by the general practitioner until the abscess breaks. It were more fortunate to the patient to subject him to surgical measures early in order to avoid the formation of fistula. Fistula has two or three origins: first, the tubercle bacillus, and second, the *Bacillus coli-communis*, mixed with pyogenic cocci. The persistence of a fistula depends on reinfection, and the pictures shown today explain how that is possible and may convert a simple tract into a complex one.

The extent of a fistula depends on three things: first, on the size of the original abscess; the ischiorectal fossa containing fat offers little resistance to the invading bacteria and the abscess is limited by its capacity. The pelvirectal space makes a large abscess possible; second, the extent of the fistula will depend on the degree of patency of the external or internal opening. A draining tract will not extend; third, it depends on the virulence of the infecting micro-organism. Fistulas are not by any means always due to the tubercle bacillus, as is popularly supposed, but all sorts of micro-organisms are found in these processes, and they are frequently very destructive of tissues.

The treatment involves the principle of drainage. The internal opening should be located, and is usually found between the ental and ectal sphincters; if the tract runs up the bowel, it is usually submucosal and can be incised with impunity and without fear of incontinence.

Dr. A. E. Chace, New York: I think Dr. Pennington has missed the real point in the relationship which lies between the intramuscular sinuses and ischiorectal abscesses, which I brought out in a paper before a New York medical society last winter. These intramuscular sinuses not only go down, as he has shown in the slides, just to the muscle, but actually into it, and in some instances almost pierce the muscle, thereby accounting for the path of infection from the rectal mucosa, through the muscle, into the ischiorectal fossa. I have no doubt that Dr. Pennington has seen the beautiful illustration of the sinuses extending into the muscle in Hermann and Defosse's original work. If he will go still further and look at the beautiful wax models by Dr. F. P. Johnson of intramuscular sinuses, he will see how well this point is illustrated. There is no question but that they are the cause, in many cases, of ischiorectal abscesses. We all have about our anal canals at least several of these long, blind sinuses which are potent of inflammatory reaction.

Dr. R. W. Jackson, Fall River, Mass.: There are two phases of fistula work of which I want to say a word. The first is on the diagnostic side. A large majority of the cases are unmistakably associated with the rectum in cause or sequence, but too many are not, or are not plainly so. There are many which originate in extra-intestinal foci, such as lesions of bone and joints, uterus and adnexa, or genito-urinary tract, but which often empty near the anus and lead to false diagnosis by the average attending practitioner. I would call attention to the value of colored solutions (methylene blue and the like) injected into the external openings, this to be followed immediately by proctoscopic or sigmoidoscopic examination to locate the point of emergence, if any, into the gut, that is, the site of an internal opening. And further, the patients should urinate immediately after such injection to show possible communication with the urinary tract; and here I use the word "immediately" advisedly, for it must be recollected that the methylene blue so injected may be absorbed and appear in the urine later by the

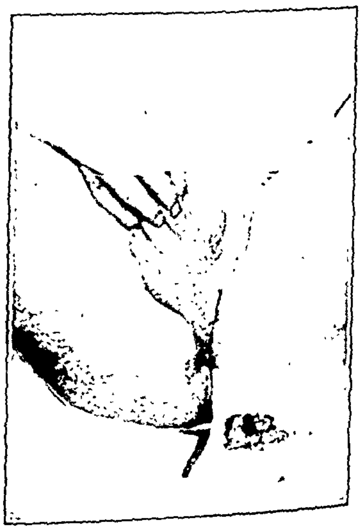

Fig. 11.—Photograph taken two weeks after the operation. It shows the operative field and the fistulous mass that was removed. One sinus extended to Poupart's ligament and another involved the scrotum, which was opened during the dissection, the testicle dropping out. The wound was closed after the method shown in Figure 10. The patient made a permanent recovery.

hematogenous route. The great value of bismuth paste injected, not for therapeutic but for diagnostic purposes, ought also to be enlarged on. The paste should be thin to reach easily the limits of all side tracts, and the main tract should contain simultaneously a probe passed to its limit. Then the picture shown by roentgenograms, provided they are taken in stereoscopic form, is often graphic indeed, a bismuth finger pointing directly at the primary focus of trouble, particularly if that be osseous. Flat, nonstereoscopic pictures have no such value. I have found these procedures invaluable in some work a description of which has already appeared in print.

The second phase is on the therapeutic side, and I would call attention to it by asking a question. Is there not a field in the surgical therapeusis of the highly septic processes about the anus and rectum for the use of the sodium hypochlorite solutions? The technic of their use must of necessity be imperfect as compared with the exact methods in use in military surgery, yet, though I am only just beginning to employ them, I believe they hold promise.

Dr. Fenton B. Turck, New York: As I understand it, this paper is presented to emphasize the idea of removing the lining wall of the fistula and the surrounding round cell infiltration by operative procedure. The fistulous tract is nothing but the result of the formation of an avenue of escape for the products of infection. The walls of the fistulous tract, and likewise the surrounding tissue, are infected. Dr. Pennington proposes to remove the products of infection from the entire infected area, bringing the fresh tissues together by suture, with the hope of obtaining primary union, as Dr. Smith proposed to do in the eighties. The objection claimed as the result of clinical experience is that many of the cases do not permanently heal because of retention of infected material. If a small drainage of silkworm gut is used, would there still be danger of reinfection, especially if the sodium hypochlorite infiltration method is used?

Dr. B. Gruskin, Chicago: I shall discuss this paper from the point of view of a laboratory man interested in infection and immunity. It occurs to me that Dr. Pennington has done valuable work by calling our attention to the infections of the lower bowel. For years we have been becoming more appreciative of the infections due to the tonsils, the teeth, etc. It has been proved that such conditions as arthritis, rheumatism and other disturbances are the result of infection from those regions; but never have we though of the fact that the lower bowel, being more exposed to micro-organisms than any other part of the body, if it should by some pathologic condition become irritated, would certainly offer the most favorable field for infection. Dr. Pennington's experiments were carried out in my laboratories, and I especially appreciate that it took an enormous amount of labor and study for Dr. Pennington to come to his conclusions, and I deem it my duty to call the attention of the profession to the importance of these researches, which will in the future throw more light on so many of the so-called idiopathic conditions.

Dr. Dwight H. Murray, Syracuse, N. Y.: I do not believe the rectum is any more liable to infection than any other part of the body because of the material that goes through it; that is, if normal; but, because of our careless habits we may through constipation, by using the rectum instead of the sigmoid as a reservoir for feces, become autointoxicated and lose our power of resistance against infection. With a normal condition of the colon and rectum we should not have infection.

Dr. Louis J. Hirschman, Detroit: In regard to the diagnosis of a fistulous tract, we have heard about the injection of colored solutions. Colored solutions run out of the tract. By reinjecting bismuth paste just before operating on a patient the contrast of the yellow bismuth against the red flesh is far more definite and much more satisfactory than a stain of methylene blue solution or black permanganate solution. Even while operating the watery solution runs out while the bismuth remains in situ and may point out something overlooked.

With regard to the remarks of Dr. Turck, most of us have always advocated the excision of the whole fistulous tract. Nine or ten years ago I called attention to microscopic submucous tracts and I advocated excision of the whole tract for that reason, and I have had no reason to change my procedure since. I believe I have had good results because I excised the whole tract.

Dr. Pennington spoke of the fistula being incised, curetting out the cavity well and packing. I have tried to curet the tract and realized the fallacy of this very soon. It cannot be done; it must be excised. Every [illegible], I am sure. I am disappointed to hea[illegible] is still sewing up fistulas. I thought we had all forgotten about that in infected tracts. I want to congratulate Dr. Pennington on the case he showed in which the patient got well without further trouble. I think it is impossible to sew up an infected tract without great danger.

Dr. J. Rawson Pennington, Chicago: I was glad to hear Dr. Chace say that he had done some original work on the rectal sinuses, and that he had read a paper on the subject before a medical society last winter. As he has not published his paper, he could not expect the profession to know about it.

I was surprised to hear Dr. Hirschman say that he thought we were through with sewing up fistulas, and that he would like to see a photograph taken six months from now of the patient whose picture was thrown on the screen. I might say that I saw the patient four or five years after the operation and that he was still well.

In a large percentage of the cases I dissect out the fistulous tract and close the wound because it unquestionably gives the best results, and there is less likelihood of incontinence. Evidently, Dr. Hirschman is not familiar with the technic for excising a fistula and closing the wound. If he will follow the suggestions laid down in the paper I think he will succeed and be greatly pleased.

THE VALUE OF MAKING LEUKOCYTE COUNTS ON THE URINE IN INFECTIONS OF THE KIDNEY *

HERMAN L. KRETSCHMER, M.D.
Urologist, Presbyterian Hospital; Genito-Urinary Surgeon, Alexian Brothers' Hospital
CHICAGO

During the past three years we have been controlling all cases of renal infection, including tuberculosis, that have been admitted to the Presbyterian Hospital, by making leukocyte counts on the urine. It has seemed to us that this was the only way one could obtain definite and exact information relative to the severity of the infectious process, and furthermore, it has been giving us an idea of the improvement in the patient's condition while under treatment.

The idea of making leukocyte counts on the urine is not a new one. Its routine use, however, in the control of urinary infections, hand in hand with bacteriologic controls, I do not think has become an established procedure. I am not familiar with any clinic or laboratory that employs the leukocyte count on the urine as a routine in its daily work, so that I believe the statement is justified, that, as a rule, this procedure is very rarely, if ever, employed in routine clinical work. Just why this should be is not clear, for it is hard to see how one can do accurate work and get along without its use as a control of the progress made in cases of urinary infection that are under treatment.

This method is particularly valuable for informing us of the progress made in cases of infection of the renal pelvis which are being treated by pelvic lavage.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

As a rule, indefinite terms, such as "more or less," and sometimes plus signs are used, when referring to the amount of pus present in the urine. In a general way, these terms, being relative, may suffice. Nevertheless, they are open to the criticism that they are not accurate and one cannot tell from time to time the exact amount of progress the patient has made. There can be no question that when one wishes to carry out more accurate work, the use of plus signs, as well as the indefinite terms at present in general use, is most unsatisfactory.

In the treatment of cases of pyelitis by pelvic lavage, one can tell absolutely whether or not the patient is making progress by a comparison of the leukocyte counts made each time the ureters are catheterized. In several instances we have noticed a transitory rise in the leukocyte count after the patients were treated with silver nitrate. We take it that this transitory increase in the number of cells was due to the medication. In many instances, the amount of fall in the leukocyte count from time to time following each treatment has been very striking, as will be illustrated in the case reports.

This method may be criticized as being inaccurate and containing the possibilities of error. Doubtless there are many factors which have a direct bearing on the volume of the urine. Nevertheless, it is surely much more accurate than no method at all, and far superior to the use of more or less indefinite terms. This method, technically, is just as accurate as is the counting of the leukocytes in the blood. In view of the fact that the blood volume is constant, the normal number of leukocytes in the blood per cubic centimeter is practically constant. The urinary leukocyte count will naturally vary with the urinary output and is subject to certain variations. The count will be high or low in direct relation to the urinary output.

In order to make our counts as nearly as possible under the same conditions, our patients are instructed to drink 6 ounces of water two hours before and 6 ounces more one hour before the urine is to be examined. Just before taking the first glass of water, that is, two hours before cystoscopy, the patient voids, so that the bladder at this time is empty.

In the cases to be reported in this series, the counts were made on specimens obtained from the right and left kidneys through the ureteral catheter and from catheterized bladder specimens. In a few instances, only the bladder urine was counted, after the kidneys were free from infection and pus.

If each count is made under the same conditions and compared with each previous count, I believe that this method has a distinct value in showing the improvement made from one examination to the next. This can be seen by referring to the case reports.

TECHNIC OF MAKING THE COUNT

In making the leukocyte counts, the urine is not centrifuged. The specimen is vigorously shaken so as to have the leukocytes and the urine well mixed. Toison's solution is drawn to the 0.5 mark and then urine is drawn to 11. This is agitated and a drop of fluid placed on a blood-counting chamber, covered with a cover glass, and the leukocytes are counted in the usual way.

As an example of the results obtained by this method, I wish to present the histories of a few cases which have been selected at random from our records of cases of pyelitis which have been treated by pelvic lavage and in which the degree of infection was controlled by making routine leukocyte counts.

REPORT OF CASES

Case 1.—J. S. F., man, aged 40, on whom a diagnosis of pyelitis with arthritis was made, had begun to have trouble six years previously with a painful swelling of the right knee. This was followed a few weeks later by a similar condition in the other knee. Since then the patient has suffered from arthritis, growing worse gradually. About three years ago the patient began gradually to have urinary disturbances. He was obliged to void about four times every night and sometimes more. There was a burning pain in the urethra.

On admission the patient urinated every half hour during the day. He has had pyuria for several years. The cystoscopic examination showed a generalized cystitis. There were many flakes of mucopus adherent to the bladder wall. Ureteral catheterization was easy and without obstruction. Examination of the urine revealed the presence of pus in the bladder and in the right and left kidney urines. All cultures have remained persistently sterile.

The result of the treatment and its effect on the leukocyte count may be seen at a glance by referring to Table 1.

Case 2.—Mrs. E. H., aged 28, on whom a diagnosis of colon pyelitis was made, had had bladder trouble for many years. She had been married nine years. On her honey-

* Cultures lost.

moon she had an attack of cystitis, with severe burning pain on urination. At this time she also had frequency, so that she was obliged to rise several times during the night. She had occasional attacks of chills and fever which had been attributed to malaria and to her appendix. She complained of pain on the right side both in front and in back. Four and a half years ago, during an acute attack of pain on the right side, her appendix was removed. She was told that it was not diseased. Cystoscopic examination proved the bladder to be negative. Catheterization of the ureters was easy and without obstruction. The urine showed the presence of pus in both right and left kidneys and in the bladder. Cultures showed *Bacillus coli.* The roentgen-ray examination was negative for calculi. The treatment was pelvic lavage.

Case 3.—Mrs. Dr. F., aged 28, on whom a diagnosis of pyelitis during pregnancy was made, dates the onset of her present trouble from the sixth month of her pregnancy. It was accompanied by severe pain in the right side and in the back. The pain gradually grew worse and was followed by a rise in temperature. The patient had several attacks of chills and fever. Her temperature varied from 95.2 to 103 F. between 1 a. m. and 8 p. m. The patient had her appendix removed for a similar attack of pain before she was married. Cystoscopy revealed a mild cystitis. Ureteral catheterization was easy and without obstruction. The urine from the right and left kidneys and from the bladder showed the presence of pus and a mixed infection of *B. coli* and staphylococci. The patient was given four treatments of pelvic lavage with silver nitrate.

Case 4.—Dr. L. R. F., a man, aged 38, whose case was diagnosed as pyelitis, was operated on in January, 1917, for hemorrhoids. Following catheterization, cystitis developed, accompanied by frequent urination and pain. The urine was examined and pus and *B. coli* were found. The roentgen-ray examination was negative. Cystoscopy showed the following: The bladder was negative. Double ureteral catheterization was easy and without obstruction. The urine from the right and left kidneys and from the bladder showed the presence of pus. The right kidney and bladder urines showed *B. coli.* The left kidney was sterile. The patient was treated by pelvic lavage with silver nitrate.

Case 5.—Mrs. F. P., aged 27, whose case was diagnosed as colon pyelitis, complained of frequent and burning pain on urination, chills and fever, and pain in the right lumbar region. Severe backache at night began about three weeks ago, which was relieved by lying on something hard. The urine became irritating and she was obliged to urinate every few minutes, both day and night. At this time she began to have chills which were followed by a rise of temperature. For a few days previous to this she had had two severe chills each day. A steady backache had been present for the last three weeks. The roentgen-ray examination was negative for stone. Cystoscopy showed the right ureter edematous and swollen. The left appeared normal. A mild degree of cystitis was seen at the base. Ureteral catheterization revealed no urine from the left kidney. That from the right side contained pus and *B. coli.* At the subsequent examinations there was no difficulty in obtaining the urine from the left kidney. The patient was given the usual pelvic lavage treatments.

Case 6.—Mrs. E. L. H., aged 41, on whom a diagnosis of pyelitis following pregnancy was made, was suddenly seized, one month after her last pregnancy, with an attack of high fever, associated with chills and sweating. Her temperature varied from 100 to 102.5 F. There were no bladder symptoms. This attack of chills, fever and sweating lasted for sixteen weeks. During this time the urine showed the presence of pus and *B. coli.* The second attack occurred last fall, when the patient was suddenly seized with severe chills and fever, associated with severe pains in the back and lumbar region. The roentgen-ray examination was negative for stones. Cystoscopic examination showed the bladder negative. Bilateral ureteral catheterization was easy and without obstruction. Pus and *B. coli* were found in the bladder urine and in the urine from the right kidney. The left kidney urine was sterile. The patient was treated by pelvic lavage.

CONCLUSIONS

1. This method is of distinct value in showing the improvement made from time to time while the patient is under treatment.

2. It can be carried out without any trouble or inconvenience to the patient.

3. No conclusions can be drawn from a single count. The value of the method must depend on making each count under exactly the same conditions.

4. This method should be considered from a standpoint of comparison.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr. Martin Krotoszyner, San Francisco: While I have no experience with comparative quantitative determination of leukocytes present in renal urines, I have for a number of years employed their comparative qualitative estimation for diagnostic purposes in bilateral renal lesions. From the difference in the shape, outline and size of leukocytes and their nuclei, valuable conclusions are feasible in many instances on the nature and extension of the bilateral process, and it is fair to assume that by these means Dr. Kretschmer's method might gain materially in diagnostic significance.

Dr. W. C. Quinby, Boston: Dr. Kretschmer has added one more method to our armamentarium. It is undoubtedly one of value, and can be performed by the clinician. Although I have not investigated the leukocyte count in the urine, I have followed such cases by the bacterial count. The urine of patients under treatment by pelvic lavage has been examined at intervals of about a week in the bacteriologic laboratory. The culture is plated and the number of colonies which grow in a given length of time counted. This can be done with a good deal of accuracy, and, to my mind, is probably better in estimating the progress of a case under lavage than counting the leukocytes. I concede, however, that counting the leukocytes is of real value if a competent bacteriologist is not available.

Dr. George A. Wyeth, New York: I should like to ask Dr. Kretschmer what he considers the normal.

Dr. H. L. Kretschmer, Chicago: About ten to fifteen.

INSOLUBILITY OF SOFT GELATIN CAPSULES *

EXPERIMENTS SHOWING THAT SOFT CAPSULES ARE RELATIVELY INSOLUBLE IN THE STOMACH

F. W. DERSHIMER, M.D.
Director of the work of the International Health Board in British Guiana

At all times, and at the present time especially, it is of great importance to both physician and patient that all drugs be administered in a form that is easily digested and absorbed. Sometimes, however, in our efforts to make medicines pleasing to the palate of our patients, we may succeed too well, with the result that the coatings protect the drugs not only from the action of the saliva, but from the gastric and enteric juices as well. Recent experiments seem to prove that soft gelatin capsules do this very thing.

In September of last year, a local firm offered us some thymol at a very attractive price, stating that they were able to quote so low a price because the thymol had been ordered before the war. Examination of the samples showed that for some reason the drug had been put into soft capsules. To test their solubility several of the capsules were put into a pepsin solution that had been slightly acidified with dilute hydrochloric acid. A hard capsule was placed in some of the same solution as a control and both were incubated at body temperature. The hard capsule broke in four minutes and had completely dissolved in twenty-one minutes. After twenty-four hours, the soft capsule showed no signs of dissolving beyond a slight softening of the outer surfaces. The offer was rejected and nothing more was thought of the matter, it being supposed that this lot of capsules had become insoluble, for some unknown reason, but that others would be satisfactory.

---

* The experiments on which this paper is based were conducted with the support and under the auspices of the International Health Board of the Rockefeller Foundation.

Recently, however, our attention was again drawn to the matter by a memorandum from the Malaya Board of the International Health Board. They reported that soft gelatin capsules, furnished by a reputable United States drug firm, were not easily soluble either in digestive solutions or in the alimentary tract. On comparative test, those capsules containing oil of chenopodium removed an average of but 77.5 per cent. of the hookworms present, while equal doses of the same oil, when removed from the capsules before administration, caused the expulsion of 97.9 per cent. of the hookworms. In other words, the capsules decreased the efficiency of treatments by more than 20 per cent.

Thinking that it might be possible that certain drugs affected the solubility of the capsules adversely, we then tested some capsules containing hexamethylenetetramin. It may be remarked that there is no apparent reason why a drug that is so nearly tasteless, even when given in solution, should be put into capsules of any sort. They were offered in the local market in that form, however. Several of the capsules were placed in a similar solution to the one used in our first experiment. After having been incubated at body temperature for twenty-four hours they had not dissolved.

SUMMARY OF RESULTS OF EXPERIMENTS

Kind of Capsules	Time Required to Release Contents When Placed in Acidified Pepsin Solution at Body Temperature
Hard gelatin capsules	4 minutes
Soft gelatin capsules supplied by two different firms	3 hours 50 minutes
Soft gelatin capsules supplied by two other firms	Not released after 24 hours

We then tested a number of soft capsules containing oil of chenopodium. These were manufactured in the United States by two reputable firms other than the one from which the Malaya Board obtained its supply. Our results were similar to those of the Malaya Board, an average of three hours and fifty minutes being required for the capsules to dissolve sufficiently to release the oil. In all cases the hard capsules used as controls dissolved in about the same time as stated in connection with the first experiment. We were not able to test the capsules by administration, as we use oil of chenopodium in but few cases here.

These experiments seem to indicate that drugs should not be administered in soft gelatin capsules, as supplied at present, with any hope that they will act efficiently.

Tongue Evidence of Infanticide.—*In a case mentioned in* the *Clinica Ostetrica* L'Lattes was able to detect by oblique illumination the regular imprint on the tongue of the child of cloth fibers corresponding to the cloth wrapped around the child.

QUININ AND UREA IN THE TREATMENT OF HEMORRHOIDS

SUPPLEMENTARY REPORT *

E. H. TERRELL, M.D.
RICHMOND, VA.

At the meeting of the American Proctologic Society in Detroit, in 1916, I read a paper advocating the use of quinin and urea in the treatment of internal hemorrhoids. At that time, although a few favorable comments were made on the paper, there was apparent a feeling of distrust on the part of some of those present. Since then, however, several members of the society, and many others, have written me of the good results obtained by the method described. It has been very gratifying to learn that others are getting equally as satisfactory results as I have been claiming.

In my previous paper 128 cases were reported. During the past twelve months, I have used quinin and urea in the treatment of 185 cases, making a total to this date of 313 patients on whom I have used the remedy. As in the previous report, I include only those cases in which some definite knowledge of results is known. There have been quite a number of patients who received one or more treatments and then disappeared for reasons unknown to me. These are not included in this report.

During the year, about 20 per cent. of the cases of hemorrhoids examined were found to be complicated by polypi, hypertrophied anal valves, fissures, etc. If the complication was such that it could be removed in the office under local anesthesia, this was done, and the hemorrhoids were treated afterward. In those cases requiring a general anesthetic to get rid of the complication, the hemorrhoids were excised at the same time. There have been quite a number of such during the year, but they have no place in this report and are not included.

Quinin and urea should not be used in inflamed, strangulated or external piles, but is a specific in that large class of chronic internal hemorrhoids, the chief symptoms of which are protrusion and bleeding. A hemorrhoid that is badly ulcerated and bleeds freely will seldom bleed again after the first treatment. To those who have a prejudice against all forms of treatment other than operative, and I know there are many such, I would suggest the use of quinin and urea solution to tide over the bad surgical risks, made so from excessive hemorrhoidal bleeding. You will be surprised how quickly the hemoglobin index will improve.

About 50 per cent. of those with protrusion are relieved of this symptom immediately after all the tumors have received one injection. With those situated lower in the anal canal, the prolapse will disappear gradually, although a marked reduction will be noticed from the beginning of treatment. Soon after a hemorrhoid is injected with quinin and urea solution, it loses some of its flexibility and becomes more or less fixed, when it can be felt very plainly with the finger introduced into the anus. This lessening of mobility accounts in many cases for the sudden relief of prolapse, for a noticeable diminution in the size of the tumors does not begin for several days after treatment. In a few days, a hemorrhoid that has been injected with a solution of quinin and urea has a glazed appearance, and is very much paler in color. A fibrosis with local anemia of the parts has been produced. On account of the fibrosis, the blood vessels are constricted, and, since the parts are denied the usual amount of nourishment, an atrophy is the result. Although the question is open to criticism, I believe this is the manner in which a cure is produced.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

I have experimented with various strengths of solution in some of my cases, and have finally come to the conclusion that 5 per cent. is approximately the right strength for the average case. Sometimes if a hemorrhoid seems resistant to treatment, as occasionally it does, I use a 10 per cent. solution with better results.

It is my custom to inject one hemorrhoid each succeeding day until all are treated; but, if the sphincters are relaxed, there is no objection to treating two or more hemorrhoids at one time. After all the hemorrhoids have received a treatment, the patient is asked to return once a week until a cure is effected, which takes about six weeks for the average case. At these visits, treatments are alternated from one side to the other, that is, the piles on the right side are injected at one visit and those on the left at the next, so that each hemorrhoid is treated once every two weeks, which, I think, ordinarily is often enough. There is no attempt made to dilate the sphincters, nor do I draw the hemorrhoids down, as is advised by some operators. Personally, I think a Brinkerhoff anal speculum is the instrument of choice in bringing the tumors into view. It is small, conical in shape, and very easily introduced. The pile selected for treatment is cleansed with an antiseptic solution, preferably iodin and alcohol. Enough of the quinin and urea solution is then injected into the pile to slightly distend it. The needle must be very small, and should be inserted at a point as far away from the skin margin as possible, the slide in the speculum being used as an aid in doing this. The injection should be made through and not into the mucous membrane; otherwise a slough is likely to occur. During the course of treatment there are no restrictions whatever placed on the patient. He is allowed to proceed about his business as usual.

Most of those who come to me for the treatment of hemorrhoids are more or less constipated, and since the latter condition most often precedes and is the cause of the former, I deem it necessary that the treatment of both be taken up at the same time. Eliminating appendicitis, bile tract infections and other like intra-abdominal conditions as causes, I have been greatly surprised to find how easily many cases of long-standing constipation are relieved. Most patients while under treatment for constipation need encouragement more than all else, and visiting the physician at regular intervals for six weeks or so, while under treatment for hemorrhoids, offers an excellent opportunity for this. At the same time, other measures deemed necessary are used. Relief from constipation, when possible, is a decided aid in the treatment of the hemorrhoids, and no doubt lessens greatly the likelihood of a recurrence.

The question of whether or not the treatment is painful has been asked many times. From the standpoint of both physician and patient, this is important. Any so-called ambulatory or nonoperative treatment for hemorrhoids that causes pain, or is likely to put the patient to bed, is a failure. An anesthetic and operation is far preferable, if such is to be the case. In fact, on general principles, I am not opposed to operations for hemorrhoids, if properly done. On the other hand, if hemorrhoids can be cured with no more than a slight discomfort and with no loss of time from business, I think it a decided step forward in the treatment.

In properly selected cases of hemorrhoids, treated with quinin and urea, as outlined, rarely does a patient complain of pain during or following a treatment. If the work is done carefully, gently, and without haste, 90 per cent. of the patients will not know when the injections are made. During the past year, in treating 185 patients, three have had pain due to complications, which I will describe. In one of these there occurred an edema of the skin below the point of injection, and it was apparently quite painful for two days. I think the injection was made too near the skin line, a danger I advised against in my last paper. In the second, there developed during the course of treatment a well marked fissure, which necessitated excision. This may have been a coincidence, but I am inclined to believe it was the result of infection from treatment. In the third, there occurred a small marginal abscess a short time after the first visit. After incision and drainage it soon healed, when treatment of the hemorrhoids was continued without further trouble. A complication, such as one of the above occurring now and then, serves to remind the operator of the necessity of a more careful technic.

During the year, every patient treated by the method described has been cured. It is fair to state, however, that among this number there were a few resistant to treatment, sometimes as long as twelve or fourteen weeks being required for a complete disappearance.

In another group, five or six in number, a hard, fibrous hemorrhoid would persist after the others, softer and varicosed, had disappeared. Such a condition is usually anticipated at the first visit, if the examiner is experienced, and a careful inspection is made. The patient should be told at this time that it will be necessary to excise the hard growth, which may be done before or after the softer hemorrhoids are gotten rid of by quinin and urea. In most of the cases with this complication, unless very slight, I have advised an operation at the hospital, when a complete removal of all the hemorrhoids is done.

The treatment of hemorrhoids by the injection of quinin and urea appears simple, and it is; but a thorough knowledge of rectal diseases is essential if one expects uniformly good results. Most important of all is a realization of the class of cases to which it is suited, and its limitations. I hope no physician will attempt to use the remedy until these ideas are thoroughly grasped.

105 North Third Street.

ABSTRACT OF DISCUSSION

Dr. Collier F. Martin, Philadelphia: Thirteen years ago I read a paper on the "Injection Treatment of Hemorrhoids" before the American Proctologic Society. I have used the injection treatment for seventeen years, and hundreds of patients have been injected, not with phenol (carbolic acid) or quinin and urea hydrochlorid, but with a 50 per cent. proprietary phenol solution. It seems to make little difference what solution one uses, providing one gets the local inflammatory reaction with subsequent absorption, and providing the solution does not produce undue complications. None but internal hemorrhoids are to be injected. These may be readily recognized, as they always are covered with mucous membrane, and are found above the anorectal line. Internal hemorrhoids are innervated by sympathetic fibers only. The spinal sensory nerve supply is distributed to the anal skin and tissues below the anorectal line. In other words, the injections are made only in a practically painless area.

Dr. Terrell gets good results because he knows the rectum, its pathology and its anatomy. He knows what tissues to avoid, and what symptoms to expect. The method is valuable in the hands of a man who takes the trouble to find out how to use it, and how to avoid complications. In the hands of an untrained practitioner, it is decidedly dangerous, and not to be recommended for general use. I have tried the solution Dr. Terrell recommends, but have experienced a little more trouble, probably because I did not stretch the sphincter muscles prior to starting treatment, depending on the anesthetic qualities of quinin and urea hydrochlorid to lessen the tendency to sphincter spasm. This year I reported a case of anaphylaxis occurring from the use of quinin and urea hydrochlorid. This does not condemn the solution, but should make us careful in our selection of patients.

Dr. A. E. Chace, New York: I do not think I ought to let this paper go by without a word of caution from a very young man, and a plea for real surgery in hemorrhoids. I have seen several hundred of these operations and, fortunately, only two deaths that could be attributed directly to the operation. The first was performed by means of a so-called sterile water anesthesia in the clinic. That man got a gas bacillus infection along the perineum, scrotum, thighs, and the anterior abdominal wall sloughed off before he died. The second operation was performed after the injection of quinin and urea. The prostatic plexus seemed to be first involved in the infection; there were abscesses in the liver, and death was of course caused by pyemia. Those are only two cases, it is true, but, just a word of caution: This is not a procedure that is without danger, and few procedures around the rectum, where it cannot be disinfected, are free from danger unless we have perfect drainage.

Dr. D. C. MacKenny, Buffalo: I agree thoroughly with Dr. Terrell. I have used this method a great many times in cases of tuberculous and old people, in whom one would not want to operate, and the results were all that he claimed for the treatment.

Dr. George B. Evans, Dayton, Ohio: I listened to Dr. Terrell's paper last year with not a great deal of favor and would deem myself an ingrate today if I did not rise and make an apology to him in public. On May 28 and 29 I had the pleasure of being the guest of Dr. Terrell and witnessed his work on ten or twelve patients. Unfortunately for me, none of those patients received the first injection. They were all patients who had received one, two, three, four or five injections. I also had the opportunity of being out in his waiting room. He did not know who was out there and the patients did not know I was a physician, and I listened to those patients tell what a good fellow Dr. Terrell is. They thought I was a patient. I asked them if there was any pain, and if one was laid up after the treatment, and I got a negative answer in every instance. I was there free hand and I watched this work carefully, and I want to say that I am convinced that he is doing good work and that these patients are cured. I have not only seen him inject these patients, but with his permission have examined a number of them.

Dr. Emmett H. Terrell, Richmond, Va.: The case reported by Dr. Chase in which infection and death followed the injection of hemorrhoids is unfortunate. I think a man doing this work should be careful of his technic. The hemorrhoids must be cleaned off with an antiseptic solution and the work done with as much care as if he were doing a surgical operation. If the work is done properly there will be few complications. Of course, we are working in an area difficult to clean, and there is always a possibility of infection.

Preventive Medicine in Turkey.—The whole problem of preventive medicine in Turkey is practically untouched. It involves the changing of a whole country from a backward, unprogressive one, where filth and disease make it a real menace to the world, into a clean, liveable country, one which might become progressively a real resource to the world's civilization.—A. R. Hoover, M.D., *The Survey.*

AUTOINTOXICATION IN CHRONIC CONSTIPATION *

HORACE W. SOPER, M.D.
ST. LOUIS

The group of symptoms generally recognized as attributable to intestinal toxemia is too well known to require recapitulation. *A priori,* the most striking fact that presents itself is the great similarity between the symptoms referable to focal infection and those of intestinal toxemia. This analogy at once suggests that the toxemia associated with chronic constipation may have a bacterial origin. In other words, that an infectious agent is present in the intestine itself. This view is supported by the recent work of Lynch and McFarland,[1] Satterlee,[2] Sailer,[3] Smithies,[4] Turck,[5] Barclay,[6] and others. As a contribution to this phase of the subject I[7] have recently reported a series of cases of pus infection of the rectum and lower colon as revealed by proctosigmoidoscopy.

Clinicians have long maintained that constipation per se could not be considered a disease entity, and have pointed out that persons in good health may defecate once or twice a week without resulting subjective or objective symptoms. However, the vast majority of individuals do develop symptoms when the bowel function is inadequate. In the symposium on intestinal stasis at the recent meeting of the American Gastro-Enterological Association, Einhorn, Smithies, Lynch, Draper and others emphasized the view that a diseased intestine is really necessary for the production of symptoms incident to chronic constipation. It appears that the question of absorption of toxic material depends on the integrity of the intestinal wall.

When confronted by a case that presents symptoms that we have learned to attribute to autointoxication, our first duty is to search for foci of infection. Investigation must be made of the teeth, tonsils, nasal sinuses, genito-urinary system, and of the intestine itself, not neglecting the rectum and lower colon. When the search is conducted thoroughly, we shall find that our cases of idiopathic autointoxication will diminish in much the same manner that the term neurasthenia is now applied to a constantly decreasing number of patients. In some cases, however, the most careful search will fail to reveal a focus of infection. Even here we may presume that changes have occurred in the mucosa that at present are not determinable by our diagnostic methods. Turck's[8] suggestion that venous stasis in the wall of the intestine may produce an increased permeability to the passage of bacteria is plausible.

We must admit that toxemia may result from chemical changes in the intestinal contents. In this connection the phenomena of anaphylaxis as exhibited by food sensitization must be borne in mind.[9]

Abnormal metabolism of the food protein is a factor to be considered in the production of intestinal toxemia. This aspect of the question is well stated by Brown,[10] who says:

> Back of the mechanics of digestion lies a problem far more complicated, far more difficult to solve, the problem of congenital or acquired hypersensibility to certain stimuli; the question of the overproduction of certain toxic substances, their chemical nature and their possible specificity, and various other questions involving more definitely physical factors, notably absorption and osmosis.

Brown's cases showed marked improvement on a low protein diet. In my own work I have often noted the good effects produced in certain cases of toxic headaches by sharply limiting the protein and reducing or omitting sugar from the dietary. Patients of this class usually present excessive indicanuria, much colonic flatus, and frothy fermentative feces. Moreover, they are, as a rule, in the habit of consuming large quantities of cane sugar. Possibly the presence of an excess of sugar may be a factor in determining the defective digestion or utilization of the food protein in susceptible individuals. Apropos of the carbohydrate element, the work of Pemberton[11] is especially interesting. He produced good results in cases of rheumatoid arthritis by a radical reduction of the carbohydrate in the dietary.

Besides bacterial infection, disturbances in the mechanics of digestion, and aberrant biochemical processes, we must consider a fourth important factor in the development of toxic conditions, namely, the central nervous system. Disturbances of metabolism are frequently encountered in the observation of the functional psychoses, particularly the manic depressive type. One such case deserves special mention. A patient whom I have observed in conjunction with Dr. Frank R. Fry, for the past three years, developed during the depressive phase, glycosuria, acetonuria, and indicanuria. In the intervals between the attacks, the urine is entirely free from these substances. Numerous cases could be cited in support of the contention that toxic states may arise primarily as a result of disturbances in the central nervous system, that they are frequently evanescent in character, and that they disappear regardless of the form of treatment instituted. I emphasize the nervous element in these cases particularly as a warning against giving credence to reports of cures, especially operative results, in patients of the manic depressive type. Milder forms of psychic and somatic disturbances are also elements of importance in the consideration of the etiology, symptomatology and treatment of intestinal toxemia.

The indiscriminate use of cultures of the *Bacillus bulgaricus,* now so much in vogue as a remedy for autointoxication, is open to serious objections. Even in carefully selected cases its value as an adjunct to treatment is questionable. The prevailing impression in regard to its therapeutic worth is probably due to the great food value of fermented milk. Another reason for its popularity is that it offers a remedy that the busy doctor may use without subjecting his patient to the ordeal of a carefully adjusted regimen.

The researches of Herter and Kendall,[12] Raehe,[13] Rettger,[14] Horton,[15] Hull[16]; Einhorn, Wood and Zublin,[17] and Rosenberg,[18] and others have shown the fallacy of attempts to secure the implantation of the *Bacillus bulgaricus* in the intestinal tract. Furthermore, they have demonstrated that diet is the most important factor in determining the character of the bacterial flora.

From the standpoint of economics, the loss in this country must be enormous, when we consider the large expense incurred in the production and distribution of cultures of the *Bacillus bulgaricus.*[19]

The daily use of purgatives is contraindicated, since they disturb the normal peristaltic rhythm. Moreover, the practice of flushing the colon by drugs or the use of water enemas is objectionable, because such procedures result in the reduction of the contents of the colon to a liquid or semiliquid state, a condition that probably facilitates the absorption of toxic material. I have made frequent sigmoidoscopic examination of such cases and have found that the mucosa is constantly coated by a layer of thin fecal matter. The same condition is present in many cases of chronic diarrhea—cases which exhibit marked symptoms of intestinal toxemia. In these cases we have a real "stasis," different from the usual conception of an accumulation of a large mass of fecal matter, but a retention probably much more injurious to the mucous membrane of the bowel.

CONCLUSIONS

1. Treatment should be directed against any existing infectious agent.
2. Reliance should not be placed on the *Bacillus bulgaricus* as a corrective agent.
3. The regular use of cathartics and water enemas must be avoided.
4. An initial radical change should be made in the dietary in an attempt to alter the bacterial flora.
5. The problem of the restoration of colonic function may demand the employment of all our therapeutic resources, medicinal, dietetic, hygienic and surgical.

ENTEROCOLONIC CONDITIONS IN CHRONIC CONSTIPATION *

GRANVILLE S. HANES, M.D.
LOUISVILLE, KY.

The fact that constipation has been and is under continuous discussion shows conclusively the lack of perfect knowledge emanating from any source. In this paper I shall include stasis and obstipation under the general term of constipation.

No doubt there is an element of truth in the various explanations of constipation, but it may be safely asserted that many of these explanations require further elucidation. In dealing with this question the surgeon and the general practitioner are apparently arrayed against each other, but, as a matter of fact, the views of both contain much that is true. The great difficulty is for us to see every phase of this immense subject.

In the first place, some thought must be given the more elementary aspects of the question. The whole scheme of alimentation provides for the onward progress of the ingested food; at some points it is retarded, while at others it passes with considerable rapidity. Wherever the ingesta are normally retarded, we are most likely to find increased delay in the progress of the intestinal contents; therefore, it is at those points that we note the greatest tendency to constipation.

Since provision has been made for the food to pass easily through the lumen of the small intestine, we do not frequently find here conditions which give rise to constipation. The character of the food ingested, and the conditions controlling the intestinal, hepatic and pancreatic secretions, together with certain varieties of catarrh do, however, have some influence in the production of constipation. The hepatic secretions, catarrhal inflammations and foods must not be considered lightly in this connection.

The first portion of the intestinal tract where we observe stagnation of the contents is in the terminal ileum. At this point there exists an anatomic obstruction which materially retards the onward progress of the ingesta, the muscle fibers of the terminal ileum being thickened and thus offering greater resistance than the intestine above.

The next point offering obstruction is the ileocecal junction, the lumen here being diminished and also further constricted by circular muscular fibers which permit more perfect control of the ileocecal opening.

CAUSATIVE FACTORS IN CONSTIPATION

In the large intestine are found the chief causes of chronic constipation, the cecum and ascending colon being concerned either directly or indirectly in a large percentage of cases in which patients complain of this symptom. Many reasons may be adduced to explain the frequent stagnation in the right colon.

1. The anatomic arrangement of this segment of the colon is such that it naturally retards easy progress of its contents. The large intestine from the cecum to the sigmoid becomes progressively smaller, the variation between the two extremities being approximately three to one. Thus it may be seen that material forced from the cecum toward the sigmoid will require a pressure from behind many times greater than if the lumen were not diminished.

2. The watery elements of the material emptied into the cecum are rapidly absorbed by the cecum and ascending colon. Because of the obstruction at the hepatic angle, the decrease in the colonic lumen, and the denser consistency of the feces, considerable force is required to propel the ingesta downward into the sigmoid.

3. A most potent reason for stasis in the cecum and ascending colon, and one which is generally overlooked or ignored, is the tightly contracted muscles controlling the terminal outlet of the intestinal tract. Not only are these powerful muscles in a state of tetanic contraction, but there is often sufficient irritation in the rectal and sigmoidal walls to cause an unnatural contraction, thus materially diminishing the normal capacity of these organs for the reception of feces. In every case of chronic constipation it is imperative that these organs be thoroughly investigated. At the time of operation for some rectal lesion, doubtless we have all noted both the sigmoid and rectum filled with water and feces, notwithstanding that a purgative had been administered twenty-four hours previously, and an enema not more than two or three hours before the operation. Again, we frequently hear patients say their "bowels are paralyzed," meaning that when they have a desire to defecate they cannot command sufficient force to expel the feces from the rectum and sigmoid. There is no paralysis in such cases, but on the contrary there is a spasticity which cannot be overcome by normal efforts.

4. There must be a normal balance of intracolonic pressure for defecation to occur normally. If there are contracted segments from irritation and the lumen is thus diminished, there must result a tendency to constipation. On the other hand, if the mucosa of the entire large intestine is actively inflamed, the walls become thickened and contracted, the lumen is materially diminished, an excessive amount of mucus is secreted, the feces are forced onward without time for absorption of the watery elements, and we then have the other extreme, namely, diarrhea.

5. Not infrequently the entire colon is found much larger than normal. Under such circumstances it is easy to understand that a given amount of material cannot pass through the colon with average rapidity when the lumen is large and the walls are unable to contract down on the contents. If the colonic lumen is comparatively small, which of necessity means thicker and more powerful muscle fibers, the contents will be propelled more certainly and effectively. The muscle fibers in the dilated colonic wall are attenuated and weak and, therefore, cannot contract on and move its contents forward with an equal degree of certainty.

6. It must also be conceded that a long transverse colon and redundant sigmoid present a physical condition more difficult for nature to cope with than when these parts of the bowel are of average normal length.

7. It seems useless to add that any growth in the intestinal lumen may cause obstruction and constipation, such as cancer, etc. Of course, as stated in the beginning of this paper, we include under the term constipation those conditions often referred to as stasis and obstipation.

With the feces in a liquid state a great deal of obstruction must be present to prevent fairly easy progress through the colon to the terminal outlet; it is the hard and formed fecal material which passes with difficulty along its course. We can readily under-

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

stand how much more easily patients expel thin and unformed feces from the rectum than when the excreta is formed and hard; and the same holds true of the passage of fecal material along any portion of the intestinal tract.

I wish to remark at this juncture that the condition just mentioned is one of great importance. Many surgeons have performed colostomies in one way or another modifying to a greater or less degree certain points in the technic of the operation, and the patients had little difficulty in control through the artificial opening. The surgeon at once concluded that the modified technic in his operation was responsible for the excellent artificial control. Whatever that modification may have been, no technic has ever been devised whereby colostomy may be done and have any degree of satisfaction in artificial control, with the colonic contents in a liquid state. On the contrary, so far as control is concerned, almost any colostomy will be a success with the fecal contents well formed while passing through the transverse and descending colon.

The same deception applies to destruction of the sphincter muscles in operating for rectal cancer, etc. With the colonic contents dry and formed when passing downward through the sigmoid and into the rectum, any control at the terminal outlet by the sphincter muscles can scarcely be necessary. Owing to the deep hollow in the sacrum, and the provision made by the sigmoid for retaining the feces, exit is delayed until forced forward by the accessory muscles of defecation, aided by peristalsis.

Attention is called to the foregoing facts because they illustrate more forcibly than any other argument I could present, the importance of understanding the difference in the amount of power required to move forward the colonic contents in liquid and solid forms.

8. In addition to the foregoing causative factors in constipation, it is my opinion that there is no element which plays a more important rôle than that of bacterial life. The organisms are so numerous, they thrive and multiply under so many varying circumstances, that it is impossible with our present understanding of germ life to properly estimate their full influence as causative factors either directly or indirectly in the production of constipation. The intestinal tract is so constructed that there is the least possible tendency for friction or the adherence of material to the mucosa. The greatest possible provision has been made for the easy movement of the ingesta by the polished epithelial surface of the mucosa, with the production of abundant mucus, which is unequaled as a lubricant.

The first effect that bacteria produce as a causative factor in constipation is an inflammatory reaction in the mucous membrane. The superficial cells become roughened by granulations, which has a marked effect in retarding the progress of the intestinal contents because of the disposition for material to adhere to the roughened surfaces. Many patients would be affected with pronounced constipation, when the mucous membrane is in this chronic state, were it not for the production of an abundance of mucus which compensates for this defect. When inflammation is active and mucus is produced in large quantities, and when the irritation is sufficient to cause contraction of the intestinal wall, we have the other extreme, namely, diarrhea. As will be mentioned later, a large percentage of constipated individuals give a history of having had, a number of years previously, an attack of some acute inflammatory disease involving the intestinal mucosa. These inflammatory areas are what might be considered the direct influences of bacteria on the intestinal mucosa.

The second influence of bacteria as factors in the production of constipation is on the musculature of the intestinal wall. As already suggested, the effect of very active bacterial life on the intestinal mucosa, whether there be ulceration or not, with the irritation of the nerve endings in the mucous membrane, the exaggerated contraction of the muscular wall, and an abundance of mucus, all taken together, produce diarrhea or dysentery. When there is gradual subsidence of the irritating effect of bacterial life on the tissues, then the intestinal walls begin to relax, the overstimulated mucous glands contract and produce a diminished amount of mucus, and the epithelial cells become granular from the chronic infection present. This stage, though months or years may have elapsed since the initiation of the infection, may be the beginning of chronic constipation. As the musculature relaxes under the influence of bacterial infection, with consequent increasing dilatation of the intestinal wall, an increased atrophy of the mucous glands, and also an increased granulation of the diseased epithelial cells, the constipation becomes more pronounced. We must recognize, however, that the degree and type of bacterial activity extends over, and may be responsible for, an infinitely wide range of varying symptoms.

The infection may be confined to comparatively narrow limits in the intestinal tract, or it may include the entire large intestine and the lower portion of the ileum. It may never invade the intestinal serosa, or it may produce extensive veils, bands and adhesions. The infection may be very mild and affect the epithelial cells of the mucous membrane only to a small degree, or it may affect the mucosa and the musculature and not the serosa. The character and activity of the germ life may be exceedingly mild or very severe. While some authors deny the existence of such a type of constipation as that recognized as spastic, it is true that certain types of irritation do exist wherein segments of the colon contract with unusual force and thus act as a source of mechanical obstruction to the progress of fecal material.

I have under observation at the present time a patient who has this condition in a most exaggerated degree. With the patient placed in the inverted position there is no difficulty in seeing one tightly contracting ring after another as the sigmoidoscope is introduced into the pelvic colon.

Again, the infection referred to often extends to the tissues of the anal outlet, and, as I have previously stated, it is at this point where we observe the most pronounced contractions to be found anywhere along the entire alimentary tract. In my opinion more stasis is produced in the large intestine and the terminal ileum by spastic contraction of these muscles than by any other factor entering into the etiology of constipation.

It is so seldom that examinations are made of the rectum, or rather the muscles controlling the rectal outlet, that it is quite impossible to estimate the magnitude of this phase of the subject. When due consideration is given this question it will be recognized that every abnormally contracted sphincter muscle is pathologic, and is a factor tending toward the production of constipation. The muscles may be very much hypertrophied and tightly contracted, and yet the patient may not complain of constipation. Under such circumstances, however, there are compensatory conditions existing higher in the intestinal canal whereby the contents are rendered either especially thin, the mucosa is unusually well lubricated, or some exaggerated lesion is present.

I will state that the chronic types of infection found at the rectal outlet are in some instances the most obstinate benign conditions that we have to contend with from the standpoint of effecting permanent relief, and this point should be borne in mind in all cases.

I have been especially interested in the source of these infections which play such an important part in constipation. It has been my observation that almost all of them have their origin in early infancy where the digestive apparatus remains deranged for a long period, or in some acute intestinal disease, such as typhoid fever, amebic infection, so-called flux, hookworm disease and other forms of infection. These attacks may have occurred years previously, yet it is significant when we note the large number of persons who have constipation and who give such histories.

Other enterocolonic lesions noted in constipation, with which you are familiar, and which have been extensively discussed during the last few years are veils, bands, adhesions and allied conditions. While these may be important factors in a certain number of instances, doubtless their significance has been greatly overestimated. In other words, there are many cases of obstinate constipation in which veils or bands are present, but if the other causative factors were removed and the veils allowed to remain, the patients would be completely relieved. Without making extensive reference to the cause of these bands and adhesions, it appears most logical that they are the results of bacterial activities, having their origin in the intestinal lumen during typhoid fever, amebic infection, flux and other inflammatory conditions. It seems to me that proof beyond peradventure has been established showing the relationship between these accessory tissues and the various infections just mentioned.

It is surprising to note the number of patients who complain of pain simulating appendicitis, in whom there is a previous history of acute intestinal infection followed, perhaps years later, by constipation, indigestion and other conditions resulting from bowel inactivity. At operation the blood vessels in the serous coat overlying the colon and appendix are found engorged, adhesions and veils are present, and the appendix is removed without subsidence of the constipation and pain. These facts show the intimate relationship between the infection, constipation, bands, veils and other results of inflammation.

I wish to refer briefly to the question of ileocecal insufficiency. That there is more frequently a reflux of the cecal contents into the ileum than was formerly supposed cannot be doubted. In a very large number of patients it has been found that one out of six has ileocecal incompetency. An ingenious operation has been devised for the correction of this defect, but it has not been satisfactorily proved that the method always gives permanent relief. If stasis in the cecum and ascending colon is the chief factor in producing ileal regurgitation, then it is evident that the cause of the stasis should be determined and relieved.

I have referred to the powerful influence of the tightly contracted, irritable and hypertrophied muscles controlling the rectal outlet, the dry condition of the colonic mucosa and the other conditions recognized as factors in the production of constipation. If these conditions exert as potent an influence as suggested, and there can be no doubt that they are important forces in producing stasis in the right colon, then it would be logical treatment to remove the cause, after which it is more than probable the ileocecal defect would be corrected. I think this is a point at least worthy of consideration.

In conclusion, I wish to emphasize that we, as physicians, should view this subject in its broadest sense. We will be able in this way to glean the facts necessary for a comprehensive understanding of the question much more successfully than by studying it from a narrow and contracted standpoint.

RECTAL CONDITIONS IN CHRONIC CONSTIPATION *

ALOIS B. GRAHAM, A.M., M.D.
Captain, Medical Reserve Corps, U. S. Army
INDIANAPOLIS

Prima facie, nothing appears easier than the diagnosis of chronic constipation. Nevertheless, in not a few cases, it may be an exceedingly difficult task to determine accurately the etiologic factor. Many cases are due to mechanical causes which, not infrequently, are never recognized or even suspected. With the improved modern methods of examination at our command, physical, gastric analysis, examination of the stool, roentgenology, and proctologic examination, to which is added the clinical subjective signs and symptoms, an accurate diagnosis can and should be made in the majority of cases.

No case of chronic constipation is diagnosed correctly or should ever be treated as such, until a thorough proctologic examination has been made. The rectum, in many cases, is found distended with feces, the patient not experiencing the slightest sensation of its presence and having no desire whatever for stool. This rectal stasis may be atonic in character, or it may have its origin in definite rectal conditions. If atonic, it usually has its onset early in life. Repeated and prolonged inattention to the calls of nature, such as indolence, absolute disregard, and even resistance, obtund the nerves of the rectum so that they do not respond to stimulation. Murray attributes this loss of the sense of rectal pressure to "carelessness, ignorance and laziness."

Rectal conditions, as a rule, are easily diagnosed by a thorough proctologic examination. This examination, by itself, is insufficient, and, in many cases, will not determine positively that the constipation has its origin in rectal conditions. I cannot emphasize too strongly the fact that identically the same rectal conditions may cause chronic constipation in one patient and yet have no appreciable influence in retarding the excretion of feces in another. If repeated digital examinations of a patient who has been given neither medicines nor enemas reveal a large amount of feces in the rectum, this alone should cause us to be suspicious of a rectal stasis. If the rectum is found to be almost or quite empty, we should feel reasonably certain that the constipation is due to delay higher up; and yet, we should not overlook the possibility of the

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

delay higher up having its origin in some rectal condition. In many cases, roentgenoscopy as applied by a skilled roentgenologist, which implies careful fluoroscopic study and many roentgenograms showing the passage of the barium meal through the alimentary tract, is the only method of examination at our command by which we can ascertain with any degree of precision or absolute certainty that constipation is of the rectal type. If rectal stasis is diagnosed, the presence or absence of rectal conditions is easily determined by a proctologic examination. Such a diagnosis enables us to assume a more positive attitude as to our ability to cure the constipation by correct treatment of the real etiologic factor.

In ulcerations, acute or chronic, of the anorectal region, defecation is frequently voluntarily inhibited from fear of the pain produced in the act. The sphincter muscle is in an irritable state, and the presence of feces in the rectum apparently excites it to frequent and prolonged contractions or spasms, with a resulting hypertrophy that may cause actual obstruction. Matthews holds that many cases of constipation are the result of spasm or hypertrophy of the external sphincter muscle, and in cases in which it has been cured by hemorrhoidectomy, the real benefit has been derived from the divulsion of this muscle. Hypertrophy of the levator ani muscles, according to Gant, may result from chronic pelvic, uterine, vesical and rectal diseases, and by contracting the sides of the rectum, may induce constipation. I have never encountered a case of chronic constipation that could be attributed to this condition. Hypertrophy of the circular muscular fibers of the intestine at the juncture of the sigmoid and rectum may also be a causative factor. This is a very rare condition, and it is not easy of diagnosis.

The rectal valves of Houston have been the cause of much discussion. That they are at times abnormally developed, that they can and do become hypertrophied, and that they may and do obstruct or impede the fecal current cannot be denied. However, my own findings have not been such as to enable me to corroborate the statements of surgeons of longer and much larger experience, that these valves are a very frequent cause of constipation. Hirschman says:

> Patients with so-called constipation who have run the whole gamut of cathartics, enemata, massage, dietetics, electricity, osteopathy, and Christian Science, have not been relieved until they have had proper proctologic examination and the enlarged rectal valves which were discovered relieved by valvotomy.

In every case of chronic constipation, the valves of Houston should be studied.

Hemorrhoids, both external and internal, may cause constipation, especially when they are inflamed or thrombosis has occurred in them. The real causative factor in such cases is the hypertrophy of the sphincter muscles, the result of constant irritation and spasm. Hemorrhoids may also attain such a size as to block or obstruct the anal canal.

Intra-intestinal tumors, such as polypi, adenomas, papillomas and fibromas very seldom attain sufficient size to retard or obstruct the excretion of feces. I recall two cases in which constipation was the result of a rectum practically filled with polypi. When complicating other rectal conditions, such as anorectal ulcerations or hemorrhoids, these intra-intestinal tumors must be reckoned as a possible etiologic factor in constipation. So long as polypi remain well up in the rectum, patients, as a rule, are not aware of their existence. When they prolapse, they may cause sphincteric spasm and hypertrophy. Prolapse of the rectum, especially when the upper portion becomes invaginated into the lower and protrudes through the anus, may cause obstipation.

Stricture of the rectum, cicatricial or malignant, always causes more or less obstipation. If well advanced there may be a combination of obstipation with a nagging, teasing diarrhea.

In fecal impaction, rectal in type, there may be a constant desire to go to stool, with an inability on the part of the patient to evacuate the mass. The levator ani and sphincter muscles may be injured. As a result of frequent and long continued spasmodic contractions, they may become hypertrophied to such an extent as to be the cause of chronic constipation after the fecal impaction has been removed.

Foreign bodies in the rectum may cause obstipation, and the symptoms are practically the same as those of fecal impaction. The foreign bodies may have been swallowed, introduced into the rectum by accident or for the purpose of concealment, or for the relief of certain symptoms.

Extrarectal conditions, such as enlarged prostate, stone in the bladder, urethral stricture, uterine and ovarian tumors, uterine displacements, pelvic inflammatory diseases, perineal lacerations, rectocele, and deformities of the coccyx are not infrequently the primary cause of the rectal type of chronic constipation.

Retroversion of the uterus, by its pressure on the rectum, may cause a partial obstruction of the fecal current, or by interfering with the normal muscular movements, diminish its expulsive force. The same is true of a heavy uterus or a large uterine fibroid, an impacted myoma, or an ovarian tumor growing between the leaves of the broad ligament and complicated by pelvic adhesions, so that it cannot move freely. Severe puerperal parametritis may involve the rectum to such an extent as to constrict its lumen even to complete occlusion.

Rectocele, as a rule associated with cystocele and prolapsus uteri, the result of extensive lacerations of the perineum involving the triangular ligament, rectovesical fascia, and anterior portion of the levator ani muscles, may render defecation impossible without manual reduction of the prolapsed parts. Hemorrhoids and other rectal conditions are not infrequently the result of these relaxed conditions, and tend to aggravate the constipation.

Gant reports two cases in which there was an orange-sized opening 2 inches above the anus, with a pouch which passed downward and backward, displacing the coccyx posteriorly; also two cases in which there was congenital absence of the coccyx, with bulging posteriorly of the lower rectum. Constipation was the result of these conditions. Sacrococcygeal tumors, and deviations of the coccyx, especially when the lower segments are fixed and project inward at a right angle with the sacrum, may be the cause of delay in the excretion of feces.

Stone in the bladder, urethral diseases and enlarged prostate may produce sphincteric spasm, with subsequent hypertrophy and constipation.

Enemas are an excellent occasional resource and of undoubted value in selected cases. In the majority of cases, however, the daily routine practice of introducing large quantities of fluid, often irritating in character, is not only injurious, but tends to aggravate, rather than to relieve or cure the constipation. John Burne, in his treatise on the causes and consequences of habitual constipation, published in 1840, says:

> Previous to the great intercourse which has taken place between France and England since the peace, lavaments were looked upon with disgust and horror, and had recourse to only on extraordinary occasions. Now they are in common use. As a means of obviating habitual constipation they are employed by some persons daily, with the effect of exonerating the large intestine more or less. However efficient they may, in this respect, appear to be, I have found from long observation that they are not free from very great objection. In the first place, they do not continue to relieve the bowels fully and freely for any length of time. In the next place, they do not dispose the bowels to resume their natural action, but, on the contrary, render them more confined. In the third place, they wash off the mucus from the intestine, which is followed by a degree of irritation and an unpleasant sense of heat, very similar to that which occurs after washing the hands in water simply. In the fourth place, the feces become more scybalous and hard under their use. And lastly, the individual does not feel the comfort or conviction of having had his bowels fully relieved, on which account he is often induced to resort to a second lavament on the same day. Lavaments fail in completely obviating or curing habitual constipation.

In every case of chronic constipation, the anus, perineum, buttocks and genital organs should be inspected and palpated, and any abnormality of these parts which might cause sphincteric spasm, occlude the anus, or in any way interfere with the excretion of feces, should be carefully noted.

Digital examination is next in order, and since most rectal pathology is to be found within the first 2 inches from the anal outlet, it is our most valuable method for detecting rectal, and even extrarectal, conditions, which, alone or together, may be responsible for delay in the passage of fecal matter. Much unnecessary suffering is the result of hurried digital rectal examinations. When the sphincters are so sensitive or tightly contracted as to prevent digital examination being accomplished without great pain to the patient, Hirschman advises dilation of the sphincters by means of local anesthesia.

Internal inspection of the anus, rectum and sigmoid is demanded in every case, and is made with the patient either in the knee-chest, the knee-shoulder, or the Sims' position. Such an examination enables us to diagnose accurately a pathologic condition involving these parts. It is essential that the rectum shall have been emptied of feces before this examination is begun. Force should never be employed in the introduction of the anoscope, proctoscope or sigmoidoscope, and it requires not a little practice in order to introduce these instruments properly and painlessly.

The treatment of chronic constipation implies the treatment of the various conditions that cause it. Rectal conditions, either alone or complicated by extrarectal conditions, are frequently the cause of deficient or retarded fecal movements. Chronic constipation is not infrequently the cause of hemorrhoids, ulcerations, excoriations, sphincteric spasm and hypertrophy. No matter whether the rectal conditions are the cause or the result of chronic constipation, their appropriate treatment, medical or surgical, is clearly indicated if a cure of the constipation is to be effected.

When the fecal stasis is the result of an atonic rectum, I have secured the best results from direct stimulation by means of mechanical dilatation, such as has been recommended and practiced by Turck, McMillan, Teachnor and Hirschman. Regarding this treatment by direct stimulation, John Burne, in his interesting treatise on constipation, published seventy-seven years ago, says:

> The bougie may, I think, be had recourse to with advantage more frequently than is customary in the treatment of habitual constipation, and some of its consequences. A bougie of moderate size introduced into the rectum and allowed to remain some minutes has been found on withdrawal to be followed by an action of the bowels. Employed for this purpose, it should be introduced 8 or 9 inches, so as to arrive at and dilate the upper part of the rectum, which, according to O'Beirne, is always contracted and in a state of spasm. The most convenient time for its employment is before rising in the morning, and its use should be persevered in daily by the patient himself.

CONCLUSIONS

1. No case of chronic constipation is diagnosed correctly or should ever be treated as such until a thorough proctologic examination has been made.

2. The same and identical rectal conditions may cause constipation in one patient, and have no appreciable influence in retarding the excretion of feces in another.

3. In many cases, proctologic examination alone will not determine positively that constipation has its origin in rectal conditions. It must be supplemented by a careful roentgenographic and fluoroscopic study of the alimentary tract. Such a diagnosis insures the patient correct treatment and satisfactory results.

4. Rectal conditions are frequently the primary causative factor of chronic constipation. On the other hand, constipation may be the cause of various rectal conditions. Whether the cause, or the result, of chronic constipation, the appropriate treatment of rectal conditions is essential if a cure is to be effected.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SOPER, HANES, AND GRAHAM

DR. HENRY ILLOWAY, New York: I fully concur in the statement that whatever value the Bulgarian bacillus has lies only in the fermented milk, its carrier, when that is permissible, and that it offers a remedy to the busy practitioner who is not familiar with all the intricacies of diets.

This matter of autointoxication is so harped on in the medical journals that most physicians have become convinced that every ailment, great or small, has its origin in the intestinal canal. The manufacturers of drug combinations have not been slow to seize on this, and circulars with reports of cases full of the horrors of autointoxication, with big headings and thick type, *"Clean up, Clean out,"* are showered on us daily.

We have had a whole series of morbid conditions thrown together into one bag, as it were, and labeled chronic constipation. Constipation may be a morbid entity, or it may be merely one of a group of symptoms of an underlying pathologic condition. When constipation is due to a fissure of the anus, or to abnormal development of hemorrhoidal tumors, or when it occurs in the course of cancerous disease of any part of the intestinal canal, it is not proper to call the case one of chronic constipation. The constipation is only one of a group of symptoms, which, if carefully studied, will disclose to us the pathologic condition that gave rise to it. When we speak of chronic constipation as a morbid entity, then we can mean only that form of constipation usually spoken of as habitual constipation, the consequence of an atony of the intestinal muscles.

The authors of the papers have not set forth the precise symptoms by which they diagnosticate the autointoxication due to chronic constipation. It is, however, just these details that would enable us to judge what they regard as autointoxication. Symptoms are susceptible of varying explanations.

Dr. Dudley Roberts, Brooklyn: The gastro-enterologist needs to know more of proctology and vice versa. Autointoxication is the fad of the day. While there are normally sensations arising from the filled sigmoid and rectum and a sense of well being attending satisfactory defecation, the hypochondriacal individual makes too much of such sensations. I am of the opinion that the symptoms that arise from stasis in the distal colon are largely pressure phenomena associated with hypochondria. I doubt that they are toxic. When infection of the part is added, it is quite another story.

Stasis in the right half of the colon, on the contrary, does, it seems to me, at times result in toxemias. What the toxic substances are and why they get to and through the liver we do not know. Our work on this subject will be unsatisfactory until we have a test of blood or urine that is more than slightly suggestive. Clinically we have such conditions. These individuals may or may not be constipated. Even in cases with diarrhea one sees long stasis in the right half of the colon. Dr. Soper has spoken of the infections of the colon; and while they may no doubt play a part, I do not feel that they represent more than a small group. I think that we shall find one of the most profitable fields for study in the anaphylactic group. From my experience I am convinced that, in some cases at least, stasis in the terminal ileum and cecum is responsible for the sensitization we see in some individuals. There is some reason for believing that some of the chronic arthritic groups are truly toxic rather than infectious. In addition there are cases such as were described by Satterlee. I feel that in these cases one should accept as a last resort the explanation of symptoms as due to intestinal intoxication, and then only when abnormal stasis in the ileum or right half of the colon can be clearly demonstrated. We must not lose sight of the fact that there are many possibilities of autointoxication from disturbances of metabolism in the liver, in the muscles and other tissues. We must always keep in mind the possibility of abnormal glandular activity as a cause of so-called intoxications. On the whole, I am inclined to the opinion that while in a small proportion of cases we have to deal with a true intestinal toxemia, the tendency at present is greatly to exaggerate its frequency and importance.

Dr. Walter A. Bastedo, New York: Among the causes of constipation Dr. Hanes included the diminution in the size of the colon from above downward, the lower part of the colon having only one third the lumen of the upper part. But I do not think that this in the slightest degree is a factor in producing constipation. The small intestine passes the food residue along at a rapid rate and empties it into the cecum quickly, because it has a special form of peristalsis; but, fortunately for us, the same kind of peristalsis does not take place in the colon, and ordinarily the food residue takes many hours to get down into the pelvirectal reservoir. In the process the contents lose much bulk, and there is no evidence that the tapering lumen is in any sense an obstruction.

In working with the intestines of animals one can make a considerable obstruction, particularly to the small intestine, and still, if there is peristalsis, observe the feces perfectly well pass the obstruction, the kink, or even a moderate weight put on the intestine. Indeed, a kink often straightens through peristaltic action, and unless it makes an anatomic stricture of marked degree, or spasm resulting from irritation, it is unimportant as a cause of constipation.

I believe that heredity is a very distinct factor in making "kinds" of bowels. I have known a family in which three members had the appendix removed; also two cousins, making five appendixes of blood relations. In all five the appendix was retrocecal. This was known as a constipated family, yet each member who had the appendix removed has become free from constipation. In another instance I saw a grandmother who had achylia gastrica, the daughter also had achylia, and the young granddaughter of 18 years had achylia. On the other hand, the grandfather, as shown by the roentgen ray, had a very redundant colon, a large sigmoid, and a movable cecum which crossed the sigmoid. The daughter had the same kind of colon, and the granddaughter has that kind of colon now. The grandfather, the daughter and the granddaughter have shown a severe degree of intestinal poisoning, but the grandmother, who has the achylia gastrica but not the redundant colon and cecum mobile, has never shown intestinal poisoning and is now a very old woman. I think that heredity from the two grandparents made a bad outlook for the two generations below.

Dr. Joseph C. Bloodgood, Baltimore: I think perhaps it may be of interest if, in a few words, I give you, as a surgeon, my experiences with lesions of the colon other than cancer, of which perhaps the larger group covers a condition associated with chronic constipation and what may accompany that; that is, leaving out all the cases in which, from a cross examination, there is no pathologic condition of the colon—no colitis in the sense of an ulcer, no organic stricture the result of an ulcer, no multiple polypoid tumors, no diverticulitis, no appendicitis—at least outside of the appendix in the region of the cecum—but a patient with chronic constipation and following, with its duration, other symptoms. I do not believe this is a single disease; I feel that it is a terminal disease. I want to impress that on you. My experience is that in the beginning I operated on more patients than I have in the last two years. I think my entire number is sixty, and in the last two years I have had two. Now, what is the explanation of that? In the first place I have never proceeded to an operation in any of these cases unless the patients were referred to me by medical colleagues who told me that they had done everything they could and wanted some help from surgery. Now, why has that taken place? One explanation is that there are more well trained gastro-enterologists in the clinic. This is absolutely true in my clinic, because, until a few years ago, we had no department at Johns Hopkins, or associated with me at St. Agnes, but since we have had such a department the men in my own room see more patients and operate on less.

Is all the credit due to the gastro-enterologists, or is there another element? I feel there is another element. Even if we cannot agree with Lane, and feel that some of the surgery, much of the surgery, or even all of the surgery of this type of colon lesion of the past has not been justified, nevertheless he has given to the colon, not only to the profession but to the public, more publicity than any other method of treatment.

Dr. Emmett H. Terrell, Richmond, Va.: It is absolutely essential for success in the treatment of constipation to be able to distinguish between conditions due to general causes and those resulting from obstruction. At times it is easy, but frequently an examiner is called on to exert all his ingenuity to define these cases. I find that a great many people are constipated because they think they are constipated. By that I mean that they are so in the habit of taking pills each night on retiring that they never give the bowels a chance to move naturally. If these people can be induced to stop the use of laxatives for a short time, with the proper regulation of their diet and the administration of a little petroleum oil, a great many cases will respond readily and without trouble.

I should like to refer for a moment to a condition commonly called mucous colitis. In these cases, while there are frequently several movements of the bowels in twenty-four hours, the patients are really constipated. The ordinary remedies which have been suggested for the treatment of mucous colitis in my hands have been absolutely worthless, and, in fact, I think irrigations of the rectum and the colonic flushings with various medicinal substances do more harm than good. I hesitate to suggest a remedy which has been found very beneficial because I cannot explain its action. I refer to the administration of large doses of bile salts.

Dr. Jerome Meyers, New York: I have followed the subject of intestinal autointoxication for a number of years and believe it is a mistake to speak of autointoxication. It is better to use the term indicanuria. The most important causes of indicanuria are improperly digested protein, the colon bacillus, constipation, with injury to the intestinal mucous membrane, possibly a lack of detoxifying power of the liver, and possibly the reaction of the intestinal contents, whether acid or alkaline.

I was interested in Dr. Soper's mention of sugar in autointoxication. Sugar does not give indican, but indolacetic acid in the urine. I followed this for a number of years, but obtained no practical results either in treatment or the examination for this acid in the urine.

With regard to protein decomposition and the colon bacillus, in fully fifty cases I have obtained results with the Bulgarian bacillus. I cannot agree with the gentlemen who hold that this treatment is of no value. Together with a low protein diet, I have seen it repeatedly clear up the most marked indicanuria in one to three weeks. One can expect no results unless a live bacillus is used and its use is persisted in for at least three weeks. The more ptotic the intestines are, the more difficult it will usually be to clear the urine of indican.

One other consideration is of importance—the intestinal mucous membrane itself, not only through possible gross defects, allowing indican to reach the portal blood, but the escape of indican through physiologic changes in the membrane, either of osmotic pressure or acidity or alkalinity. Protein decomposition is an alkaline process. It is interesting that the use of the *Bacillus bulgaricus*, which causes an acid reaction, should cause a diminution in the amount of indican. Again, in the use of Carlsbad or Vichy salts, both of which are strongly alkaline, I have been highly interested to note that whether the protein were restricted or not, or whether *B. bulgaricus* were given in conjunction or not, the amount of indican in the urine, even though the patient felt better, was never very materially decreased, and might even be increased.

Dr. Martin E. Rehfuss, Philadelphia: We know the roentgen ray gives a so-called cast of the interior, and absolutely nothing regarding the chemical functions of the bowel, stomach or any of the organs. Today we are in a position in which we need methods of precision. One of the matters recently investigated was the question as to what actually exists chemically in the bowel and the method of obtaining samples for analysis. Diagnosis is based on the examination of a test meal, the roentgen ray and physical examination. By suitable apparatus it is possible to remove material from different parts of the bowel and demonstrate the changes in the bowel itself. We know the cecum is rich in bacterial mediums. The observations on this are too numerous to mention. This has been borne out in examinations of a number of Lane's cases seen in Paris and in this country. None of Mr. Lane's patients are in perfect condition for any length of time. The curious thing is that the material removed from different sections of the bowel is different. I do not know the explanation of this phenomenon, but as one continues to irrigate the bowel one can demonstrate unquestionably the difference in the intestinal liquid. One can fill up the colon with liquid and cannot outline the dulness because almost invariably there is air in the bowel. Therefore, that method must give way to the method of palpation which differs with the degree of retention in each individual case. As the bowel is emptied the material will change and get lighter in color, and suddenly there may be found a large amount of putrid material, darker in color. Then again, for a half hour one may obtain nothing. We have used this procedure in several hundreds of cases but are not yet prepared to say what method is best for examining the specimens after removal. We simply examine the specimens from different levels microscopically. Although a half hour's irrigation frequently gives nothing, we then get material which may contain cellulose, leaving no doubt in our minds whatever, as to the fact that material is from high in the bowel; then we get another type of material. We use on an average from 6 to 8 gallons of liquid, and never introduce the rectal tube beyond 4 inches in the bowel, because further introduction is difficult. All the cases have been proctoscoped. Most of the problem remains to be solved, and until we do this we cannot possibly realize what autointoxication means.

Dr. W. L. Chapman, Providence, R. I.: We have been talking about autointoxication and have been told a number of times that there is no such thing. The painstaking labors of many clinicians and chemists have either been forgotten or discounted. Not once have natural methods of cure been mentioned. There are many cases of hard-working, sedentary people who have to be careful in their diet, but let them browse around on a farm for a few weeks, live out of doors, swim, play tennis, or work in a garden, and they can eat all sorts of indigestible things and "get away with it." Take the poor dyspeptic shop girl and give her two or three weeks in the country and see how her digestion improves!

We see many cases in which the abdomen sags, and by simply exercising the abdominal muscles the abdominal tone is restored and the first thing one knows the bowels will act without any medicine at all. Physical therapeutics will do much.

Every patient who comes to the gastro-enterologist should have a complete physical examination beginning with the teeth. The nose and throat men take out the tonsils because they are carriers of infection, leaving decaying teeth which should be removed at that time. If not competent to extract teeth, a dentist should be in attendance, thereby saving the patient the trouble of another anesthetization, which in children is difficult to obtain. Again, it is not beneath the dignity of a surgeon to clean up the mouth after an abdominal operation, or have it done.

Every patient should have a complete roentgenologic study of his entire gastro-intestinal tract. Until one has this one knows nothing about the orientation; whether the colon goes in a straight line or is soldered to the bladder by adhesions. If the patient is to be operated on all the important points should be recorded for the surgeon.

Dr. Milton J. Lichty, Cleveland: Gastro-intestinal autointoxication, nervous headaches and the uric acid diathesis are things talked about in my office by my patients, who know practically as much about them as I do. If we could get rid of some of this talk it would save time and also help the patients. I really believe that what Dr. Bloodgood mentioned with regard to the relation of the internist, the gastro-enterologist, to the surgeon is the thing which is going to help us out. There is no doubt whatever in my mind that many of the cases of so-called neurasthenia or constipation years ago were nothing more or less than surgical conditions, and yet we find now that they are not. The teeth and tonsils have just been mentioned. In addition to the teeth and tonsils, we have Jackson's membrane, retrocecal appendix and surgical conditions of the rectum, as well as the surgical appendix to account for symptoms. I want to remind you that the first attempt must not be considered as final. I have a record of three patients who said their appendixes had been removed, but the constipation persisted, and on a second operation the appendix was found there still making trouble.

Dr. Thomas Charles Martin, Washington, D. C.: I wish to call attention to three mechanical factors: the proctoscope, the patient in the knee-chest posture, and the rectum. The rectal valve is a factor in the production of organic obstipation. The hypertrophied valve becomes obstructed to a further degree, rectitis resulting, with infiltration; fixation results, establishing annular stricture, further contraction, and then the establishment of a tubular stricture of the rectum, the foundation being a normal stricture of the rectal valve resulting in symptoms of obstipation. We have the same form with a congenital condition.

Another form of obstruction is that due to angulation of the sigmoid flexure on the rectum. The proctoscope would indicate the obstruction within the rectum. The roentgenogram will only show such a condition as this when the picture is stereoscopic. We must be able to get the third dimension—the depth—shown by the use of the stereoscopic method of taking roentgenograms. One point already made must be emphasized: the importance of training the muscles on the front of the abdomen.

Dr. J. A. Rubin, Pittsburgh: In considering the part the colon plays in this question, let us for a moment examine the anatomic position this section of the alimentary canal occupies in the abdominal cavity as revealed to us by the fluoroscope. As Dr. Chapman has said, it is only by the aid of the roentgen ray that we can accurately study these parts. The following may be found:

1. A normal condition; that is, ascending colon to liver, transverse colon above umbilicus to spleen, and descending to the sigmoid. In chronic constipated cases this condition is rarely found.

2. Prolapse of the ascending colon over the cecum. The transverse colon, starting from the pelvis, passes up to the spleen and turns a sharp angle to form the beginning of the descending colon.

3. Complete prolapse of the transverse colon, which lies on the pelvic floor with the hepatic and splenic flexures at about the level of the anterior superior iliac spines. Between these extremes there are innumerable variations.

The next question anatomically is whether this colon in its abnormal position is freely movable and can be pushed into normal position or is adherent. A movable colon may functionate fairly well even when in an abnormal position, but I have not as yet found an abnormally placed colon bound down by adhesions that was able to do so.

Dr. G. Reese Satterlee, New York: There are five points which I wish to bring up—three old and two new ones. First, the education of the patient is an important thing. Patients now find that their cases have been wrongly diagnosed as neurologic when they are really intestinal. In fact, these patients are able to make a better diagnosis than some of the physicians, and send their friends to the gastro-enterologist.

The second point is that intestinal toxemia can be made more simple if classified into putrefactive cases, absorption of amins and diseased conditions of the colon.

Third, familiarity with the roentgen ray, not the technical side necessarily, but with the reading of the plates and with the fluoroscope, ought to be a part of the training of every internist and gastro-enterologist.

Fourth, a chemical blood examination is necessary in any patient on a diet, and carbohydrates should not be given to patients who have a high blood sugar.

Finally, I find that autogenous forms of vaccines are most efficient, and employing them often relieves us from the trouble of using massage and other measures, and in addition affords a chance to study the patient's anaphylaxis. It is essential to obtain the feces for culture after catharsis in order to get cultures from the cecocolon. I have secured satisfactory results in this way.

Trained Nurses in France.—It is not so many years since European physicians publishing their "Impressions of America." in their home medical journal always paid amazed tribute, if not in the first paragraph, at least on the first page, to the "American trained nurse." In France, the quarters appropriated to the nurses in the tradition-bound hospitals were not such as to invite the gentlewoman class to take up nursing as a profession. All this has now been done away with, and even before the war excellent training schools for nurses were well under way. The Assistance Publique, the centralized organization of all the charity hospitals and asylums in the Paris district, has now a fine new building as the training school for nurses to serve in the institutions caring for the sick poor. This new building is located in the maze which forms the great Salpêtrière hospital, founded in 1656 as an asylum for beggars. The new training school was inaugurated in 1907 and gives a three year course. The graduates pledge themselves to serve for three years in some of the institutions in charge of the Assistance Publique, after which they are free to take up private nursing. But those that remain with the Assistance Publique are entitled to a retiring pension. Before this hospital was founded, however, a training school for nurses recruited from the ranks of gentlewomen was founded, practically at her own expense, by Mme. A. Fould, in 1905. This school is said to be a model, and attractive in every respect. It gives a two year course, and the nurses pay about $20 a month during the first year. Other well equipped and well managed schools were founded about the same time by Miss Chaptal and others. One is now affiliated with the new Edith Cavell hospital school.

Clinical Notes, Suggestions, and New Instruments

ROENTGEN PLATE ILLUMINATOR, GIVING A PERSPECTIVE VIEW

J. J. Singer, M.D., St. Louis
Instructor in Clinical Medicine, Washington University Medical School

A roentgen-ray machine is no better than its plate when viewed in an illuminator; consequently, the better the illuminator, the better the value of the roentgen-ray machine.

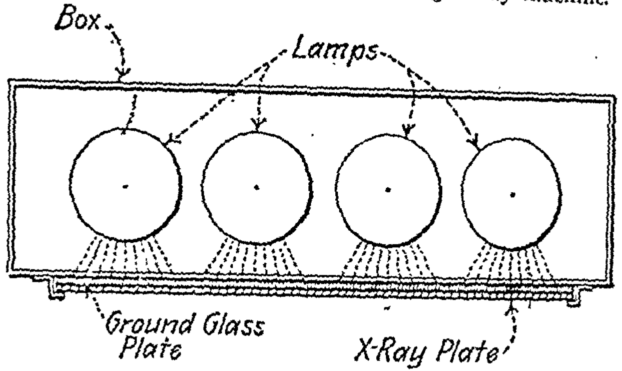

Fig. 1.—Top view of ordinary illuminating box.

Figure 1 is the top view of the ordinary illuminating box, with the lights directly back of a ground glass plate. This plate then becomes a source of light, emitting light rays of equal intensity through the roentgen plate. It will be necessary here to call attention to the fact that a roentgen plate represents in black and white the obstruction to the roentgen rays as they penetrate the body; therefore, the plate represents an uneven distribution of rays caused by the varying densities through which the roentgen rays must travel; in other words, the plate has been produced by uneven light.

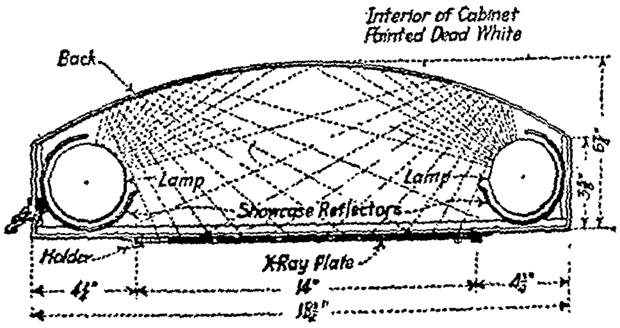

Fig. 2.—Top view of box described by the author.

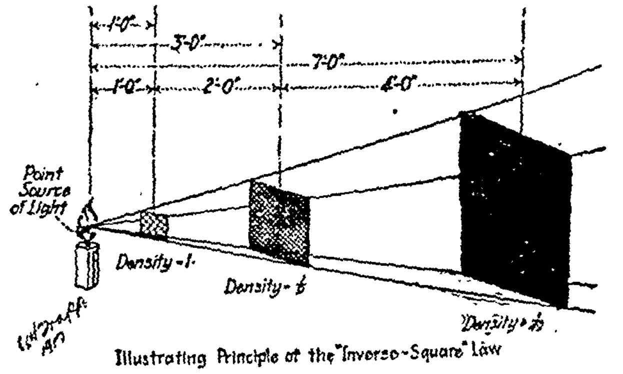

Fig. 3.—The principle of the "inverse square law."

Figure 2 is the top view of my box, in which a light is hidden on each side, the rays being reflected from a curved back, as indicated. It will be noticed that there is no ground glass plate to distribute the light evenly, the rays penetrating the plate according to the strength of the individual rays.

The center of the roentgen plate is lit up by rays of considerable length and consequently of weaker strength, and owing to this fact a weak illumination is produced in the center of the plate, which accounts for the perspective view.

In Figure 2 are given exactly dimensions best suited to my illuminator.

Figure 3 illustrates the principle of the "inverse square law." One can readily see from this drawing that the penetrating power of the light wave becomes rapidly weakened, that is, inversely as the square of the distance from the source.

Figure 4 gives a perspective view of the box, which is made of sheet tin, iron or steel, with a curved back.

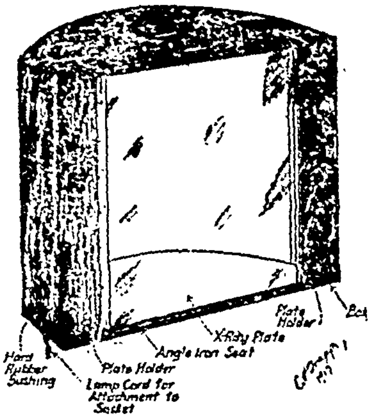

Fig. 4.—Perspective view of the box.

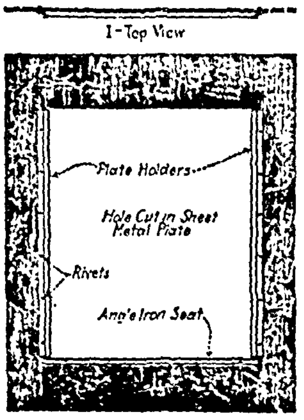

Fig. 5.—Adapter for smaller plates.

Figure 5 shows an adapter for smaller plates, the outside dimensions of the adapter being 14 by 17 inches. The inside opening can be made for any size plate desired.

The box is being used with satisfaction at the tuberculosis clinic in Washington University Medical School.

While there are other boxes being used that have indirect lighting, I do not know of any box in use that resembles the one I have described.

CONCLUSIONS

1. The box is simple, portable, light and cheap. Any mechanic is able to construct one.
2. The perspective effect of this box depends on a proper interpretation of the physics of light waves.
3. A roentgen plate should be unevenly illuminated, just as the plate was originally produced by an uneven light.

Carleton Building.

DEVICE FOR ROENTGENOGRAPHIC LOCATION OF BULLETS AND OTHER FOREIGN BODIES IN WOUNDS

Sinclair Tousey, A.M., M.D., New York

Localization by means of roentgenography presents no difficulty in the case of a finger. Here there are distinct landmarks, and it is easy to take two pictures in planes at a right angle to each other. If we employ a ray vertical to the plate at the supposed position of the foreign body, the latter is so near the plate that no correction is required for the slight lateral displacement of its shadow if not exactly at the spot where the ray is normal. In many other situations, however, two pictures at a right angle are either impracticable or inadequate, owing to the thickness of the part, the absence of very accurate bony landmarks, and often the great distance of the foreign body from the surface. The exact depth at which the foreign body is located is the difficult problem.

The methods of localization now in use fall into two groups: (1) the McKenzie-Davidson type, and (2) a method to which no distinctive name is attached. My new device is a modification of the latter type.

DETAILS OF METHOD

Apparatus Required.—1. A piece of galvanized iron netting measuring 8 by 10 inches, with meshes one-eighth inch square, the wire being of such a thickness that there are seven meshes to the linear inch. 2. A single distinctive lead marker like a small ring. 3. A set of lead numbers. 4. Facilities for moving the roentgen tube laterally a measured distance after the first exposure. 5. A stereoscopic plate holder for the exceptional cases in which two exposures should be made on separate plates.

Manipulation.—The distinctive lead marker is fastened to the skin at a point where it will be in contact with the center of the plate during the exposure. The position of this marker is indicated on the skin with an indelible pencil. The plate, covered by the wire netting, is laid on the table. The lead serial number is invariably placed over the lower external corner of the plate. The same number should be marked on the skin with an indelible pencil. Lead markers R and L (right and left) will be of occasional service. For the thigh or any part of the head or trunk, the anticathode is placed at a distance of 21 inches from the plate; it is displaced laterally 3 inches after the first exposure. For the forearm or leg the distance from the anticathode to the plate is 14 inches and the lateral displacement 2 inches. Each subdivision of the wire mesh (one-seventh inch) that the image of the foreign body is displaced corresponds to one-half inch distance from the plate to the foreign body when the exposures were made. If this distance is considerable, one must bear in mind the fact that the foreign body is located in a direction from one image to the corresponding position of the anticathode, not necessarily in a direction vertical to the plate. Each exposure should be of the same intensity and duration as for a single picture whether the exposures are made on the same or on separate plates.

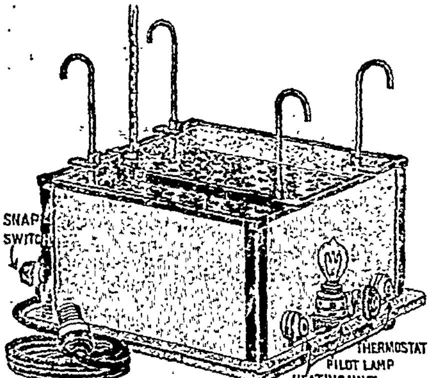
The advantage of this method lies in the small space required for the apparatus and in the absence of any mathematical calculation.

850 Seventh Avenue.

AN ELECTRICALLY HEATED CONSTANT TEMPERATURE WATER-BATH FOR SEROLOGIC WORK *

Oscar T. Schultz, M.D., Chicago

For serologic work a constant temperature water-bath is a necessity, and a bath heated and controlled by electricity has manifest advantages over any other kind. While there are several electric water-baths on the market, they are not entirely satisfactory, either because the size is excessive in comparison with the available working space, or because the regulating and heating attachments are cumbersome and in the way. A bath made according to our specifications appears to overcome these objections. Modifications as to size, but which will still retain the more important features of the bath, may suggest themselves.



CHICAGO SURGICAL & ELECTRICAL CO.

Fig. 1.—Water-bath with two test tube racks.

The bath illustrated in Figure 1 was designed to carry two metal test tube racks, each measuring 8¾ by 4 inches and 2¾ inches in height, and each with a capacity of forty-eight tubes of the 3 by ⅜ inch size, as shown in Figure 2. These racks are suspended by adjustable supports from the sides of the bath in such a way that the tubes can be submerged to any desired depth. To overcome the waste of space which is one of the features of a circular bath, this bath is made square in shape, the inside dimensions being 9 by 9 inches and 5 inches in depth. The bath is made of No. 19 sheet copper, the inner surface of which is tinned. Outside of this is a layer of hair encased in building paper, and this in turn is covered by transite (a mixture of asbestos and Portland cement) three-sixteenths inch thick. With this insulation there is no appreciable loss of heat from the sides or bottom of the bath. The total thickness of the wall is five-sixteenths inch.

---

* From the Nelson Morris Memorial Institute for Medical Research of the Michael Reese Hospital.

The bath is heated by two replaceable units placed in copper tubes 1 inch in diameter at the bottom of the bath, the tubes being entirely surrounded by water. Regulation of the temperature is effected by a removable, pencil type, bimetallic thermostat, also placed in a copper tube one-half inch in diameter at the bottom of the bath between the heating units. The latter are so wound and connected that one half of each unit, controlled by a single snap switch, may be thrown out of the circuit as soon as the desired temperature is reached. The remaining half of each unit, which is entirely independent of that portion of the system for rapid heating, is controlled by the thermostat, and serves to maintain the uniform temperature desired.

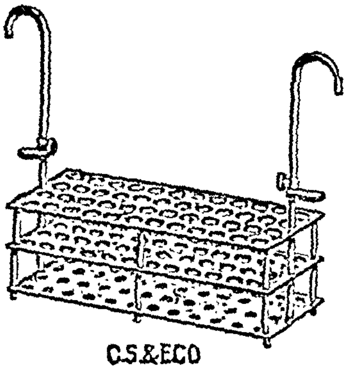


Fig. 2.—Test tube rack.

The advantages of the bath described are neatness of appearance, compactness, and absence of bunglesome attachments.

A CASE OF GAS EMBOLISM

Edward von Adelung, M.S., M.D., Oakland, Calif.

A man, with advanced pulmonary tuberculosis of the lungs, and extensive pleuritic adhesions, was given nitrogen injections in an attempt to induce pneumothorax.

The treatment was begun at 3:15. The manometer failed to register oscillations so necessary for safety. This fact, however, was unfortunately disregarded, and from 15 to 20 c.c. of gas were allowed to flow slowly into the left thorax. In two or three minutes the patient complained of "cramp" in the right leg. He was turned over, on the supposition that the "cramp" was due to position, strain or compression. The operator's attention was then distracted for a moment, and when he again looked at the patient he noticed that the head rotated to the right, that the right arm and leg were paralyzed, and that the patient was unconscious. The eyes were turned to the right, the skin was pale, and the veins stood out prominently over the right shoulder and arm. Gas embolism was immediately recognized, and the following treatment was begun, after discontinuance of the nitrogen inflation:

A hypodermic or camphorated oil (0.2 gm. of camphor) and a hypodermic of 2 c.c. of whisky were given. Then 10 c.c. of blood were withdrawn by syringe from the right arm. Hot wet cloths were applied to the head, chest and abdomen.

The pulse was small, the blood pressure 100, and the respiration and pulse regular. There was slight cyanosis of the ears and fingers. The knee tendon reflex was active. Presently the eyes began to roll. The pupils were moderately dilated.

After forty minutes the patient was able to move his right leg and arm, and he gradually improved. In forty minutes after the onset he was able to answer questions, but he was still dazed. He did not complain of pain. Fifty minutes after the onset, he was much improved, regaining control of the right arm. At 4:10 he was smiling and laughing, but was not feeling natural, and he had slight numbness in his right arm.

The patient was put in a hospital bed for observation, and the next morning the numbness had disappeared. As he felt quite well, he went home.

This case is placed on record to illustrate the need of guidance by the manometer in the induction of pneumothorax. As the notes were dictated during the time of the accident, they are accurate as far as they go.

Military Medicine and Surgery

THE MILITARY ORTHOPEDIC RECONSTRUCTION HOSPITAL

LEO MAYER,* A.M., M.D.
NEW YORK

In England, under the direction of Sir Robert Jones, and in Canada, through the Hospitals Commission, organized effort is being made to reclaim the crippled soldier. In Germany, a similar movement was initiated by Professor Biesalski, secretary of the Organization for the Care of Cripples and of the Orthopedists' Association. In France, a layman, the mayor of Lyons, Monsieur Herriot, laid the foundation by establishing a school for crippled soldiers. In each of the belligerent countries, the necessity for intelligent care of those crippled by the war has been appreciated, and means, more or less adequate, have been found to meet it.

I wish to emphasize the importance of what is called the orthopedic reconstruction hospital. Of the soldiers unfit for further military service—the blind, those suffering from internal diseases, the psychopathic and the crippled—the first three groups can be cared for by an extension of the existing hospitals and institutions. For the crippled soldier, however, no institution exists that can properly care for his particular need, since he not merely requires medical treatment, but must frequently be equipped with an artificial leg or a brace, instructed in its use, and shown how to earn his livelihood despite the physical disadvantage under which he labors.

The injuries which tend to cripple may be divided into six classes:

1. Amputations, of which we can unfortunately expect a large number since, despite modern conservatism in surgery, the high explosives used in the present war, all too frequently produce a type of wound that necessitates sacrifice of the limb.
2. Bone injuries, malunited and ununited fractures, and cases of chronic osteomyelitis due to sequestrums or foreign bodies embedded in the bone.
3. Joint lesions. These may be contractures, due to long continued immobilization or to injury in the neighborhood of the joint, bony ankyloses, due to extensive obstruction of the joint, or painful joints due to inequality of the articular surfaces, foreign bodies or to disease.
4. Nerve injuries, either complete division of the nerve, or embedding in scar tissue.
5. Division of the tendons.
6. Static deformities of all types.

Characteristic of these six groups is the lengthy postoperative treatment required in almost all instances. For instance, to discharge a patient with a musculospiral paralysis from a hospital immediately after the operative wound has healed is to leave the task half finished. The patient must be given effective aftertreatment—massage, electricity, and the proper splint—if the operation is to result in a return of function. Or take the case of a patient whose flexor tendons in the palm have been divided by a bullet. The operation is almost certain to be a failure if adequate postoperative exercises are not carried out under the eyes of a competent physician. Even those who have suffered amputation are not ready for an artificial limb immediately after the wound has healed, but the stump must be hardened and must reach a constant form before the proper prosthesis can be applied. Learning to use the artificial limb also requires time, since, particularly in the case of an artificial hand, its use is a fine art. To give a patient an artificial hand, with instructions to go ahead and use it, is like presenting a man with a violin and telling him to go ahead and play it.

---

* From September, 1914, until February, 1917, orthopedic surgeon to the Red Cross Base Hospital "Am Urban," Berlin, Germany.

Thus from the very nature of the injuries, the orthopedic reconstruction hospital has to include departments which in times of peace are not thought of in connection with medical institutions. The operating room and the ward must be supplemented by the workshop, the agricultural school and the business college. The vocational department serves numerous important purposes. In the first place, it affords the most rational and effective means of exercising joints and muscles, stiffened and weakened by long continued disuse. The Zander exercises, which have hitherto been in vogue, are exceedingly irksome for the patient and uninteresting to the physician. To the soldier, naturally depressed by a long drawn out recovery from a severe wound, the therapy should not only be directed toward physical recuperation, but should also give a psychic stimulus. Few things appeal to a man more than manual work in the carpenter shop or in the smithy, and the interest in the product of his labor will frequently enable him to perform movements that would otherwise be impossible. Thus, for instance, I recall in particular the case of a 6-foot petty officer whose right shoulder had been stiffened by an extensive periarticular gunshot wound. After the wound had healed, he was exceedingly depressed because he maintained he could no longer continue at his trade. After three weeks in the carpenter shop, under careful medical supervision, beginning with light work, such as varnishing and gradually progressing to the heavier —hammering, sawing, etc.—he had regained at least 75 per cent. of the normal movement of the shoulder and, still better, his psychic condition had become normal. He was now convinced that he could remain a carpenter.

In other instances the workshops are particularly important in training those who have undergone amputation. The first reaction of a man who has lost a limb is the sensation of hopeless crippledom. He is usually convinced that he will have to retire and live on his pension or at best eke out a living by a porter's or janitor's job. My experience, however, has been that practically every such patient can continue in his own vocation or in one allied to it. Amputation of the hand does not prevent a man from continuing to be a carpenter, smith, brace-maker, bookbinder or farmer, since with practice the lower arm stump acquires sufficient dexterity to replace the amputated hand. In the crippled children's hospital, with which I was associated, we had a 16-year-old apprentice who, despite amputation of the right hand, had become an expert brace-maker. This lad acted as instructor to soldiers with a similar type of amputation, and within two months taught them to work with a skill and enthusiasm equal to his own. When the amputation has occurred above the elbow, the problem is much more difficult. Here recourse must be had to an artificial limb. Many men can, with the aid of a suitable prosthesis, such, for instance, as the Siemens-Schukert arm, continue at the previous occupation. If the amputation has occurred near the shoulder, or if the arm has been disarticulated, it is, however, extremely difficult to handle the usual tools of carpenter, smith or cobbler. Then the patient must be trained in an allied branch. The carpenter, for instance, may become a foreman or he can learn to be a piano polisher, since in this trade practically all the work is done with a sweeping motion of one arm. Those who have suffered amputation of a leg require comparatively short training before they realize their fitness to continue in their old occupation. For them a few ingenious devices, such as the cobbler's bench with mechanical device to hold the shoe in place with a strap, are of great advantage. To all patients who have been equipped with artificial limb or with brace, the workshop affords ample opportunity to test the efficiency of the apparatus.

To the hospital the workshops are a distinct economy and a convenience. No need for plumbers, glaziers, bookbinders, printers or carpenters, when all this work can be done in the shops conducted by the hospital itself. Particularly advantageous is the brace-maker's shop. Even in times of peace the number of expert brace-makers hardly suffices for the need of the orthopedist. In times of war, when the number of maimed multiplies with tremendous rapidity and when the number of brace-makers diminishes because of conscription, it is practically impossible to supply the needs of crippled soldiers unless adequate provision is made for training men in this complicated handicraft. With two or three skilled men in charge of the shop, the soldiers with a mechanical turn can be taught one branch of the craft, and those with experience in leather work—saddlers and cobblers—can be taught another, so that in time skilled workers can be supplied.

As a necessary adjunct to the vocational department is the employment bureau. It is manifestly unfair to discharge a crippled man who has risked his life in the service of his country without helping him to secure a position of maximum advantage to himself and to the community in whose service he has been crippled. Here is opportunity for the hospital to cooperate with the state employment agencies.

It is distinctly advantageous to include the vocational department in the hospital instead of establishing separate institutions for it. Time is gained, the method is more economical and, above all, vocational work can be begun at the psychologic moment. The treatment of gunshot wounds of the extremities involves in almost all cases a lengthy after-treatment. During this time, while the patient is under medical supervision, vocational work should be begun. The physician, to whom the patient naturally looks as guide because he, far more than any other, has the patient's confidence, helps overcome the inertia which the crippled are almost certain to feel. Having workshop and hospital ward in the same institution helps build up an *esprit de corps* which it is difficult to secure in any other way. Of course, a necessary condition to the success of such a hospital is the character of the medical director. He must not only be a well trained orthopedic surgeon, but he must have a social conscience and be interested in the individual needs of each one of his patients.

The vocational work should include not only shops but also courses in farming and dairying, business courses, culture courses, training for civil service examination, etc. For every man, no matter what his previous calling has been, the hospital should offer some means of instruction that will enable him, despite the physical disadvantage he has suffered, to leave the hospital a more productive member of the community than at the time of his enlistment.

It would be unwise and unjust to leave work of such importance to local control or to private initiative. The national government itself in its war program must include not only the equipment of its armies and its hospitals for treating wounds in the acute stage, but also the adequate medical, vocational and social care of the crippled soldier. Under the direction of Major E. G. Brackett, this work has already been begun. The movement deserves the hearty support both of the medical profession and of the entire community.

41 West Eighty-Third Street.

DIGITALIS THERAPY AND THE PRESENT SHORTAGE IN DRUGS

ROBERT A. HATCHER, M.D.
Professor of Pharmacology and Materia Medica, Cornell University Medical College
NEW YORK

The following brief review of the present status of the materia medica of the digitalis group and its relation to therapeutics has been prepared at the request of Prof. Julius Stieglitz, chairman of a committee on synthetic drugs, appointed by the National Research Council, because of the present want of many preparations of this group that have come into more or less widespread use.

All of the members of this group, including many crude drugs and their galenic preparations, as well as glucosidal active principles, exert a qualitatively similar therapeutic action on the heart when they are brought into the blood stream; but the various members of the group vary enormously in their activity and in the rate of their absorption from the alimentary tract.

These differences in behavior of the different members of the group have resulted in the development of faith in one or the other of the numerous preparations and specialties, and a corresponding distrust of all others on the part of those physicians who have not appreciated the importance of dosage and the several methods of administration best suited to the individual preparation in securing the results aimed at. Those who are thus left without the preparation to which they are accustomed feel the want keenly, and the present discussion is designed to point the way to relief from these conditions.

Digitalis, digitoxin, strophanthus, strophanthin and ouabain exert the same kind of action on the heart directly, and on the circulation indirectly, as previously stated in different words; but the action of digitalis and its most active principle, digitoxin, is far more lasting than that of the others. It is necessary to caution the reader against confusing "actions" and "effects" in this connection.

When an attack of acute cardiac dilatation is relieved by any member of the group whatsoever, the effect is permanent, provided the cause of the failure is not continuously active; but in various forms of chronic cardiac disease which require more or less continuous digitalis medication, the duration of effect and the duration of action are nearly the same. In such cases the duration of action and effect of digitalis and digitoxin are far greater than those of the other members of the group, in which case the difference is overcome by increased frequency of dosage, or, what amounts to the same thing, a relatively—not actually—larger dose of equal frequency.

Digipuratum is one of those specialties that have come into wide use partly through their intrinsic value, but mainly because of a most persistent and effective campaign of adroit advertising, and it may be taken as an example of the specialties on which all too many clinicians have come to fix their sole reliance in digitalis therapy. It is certainly true, however, that while digipuratum, like many other specialties, exerts a satisfactory cardiac action, it is in no way essential, since exactly the same actions can be induced by official members of the group in the hands of any one who masters the really simple technic of administration.

In all cases requiring digitalis therapy, digitalis itself in the form of the powder, the tincture, fluidextract, extract or infusion may be used orally with the sole exception of those relatively rare cases in which immediate relief is imperative, and which require intravenous or intramuscular administration. In such cases the typical digitalis action can be induced immediately by the intramuscular or intravenous injection of strophanthin or crystalline ouabain (so-called crystalline strophanthin, not true crystalline Kombé strophanthin, which is not commercially available).

It is necessary to call attention again to the difference between an immediate action and immediate effect, because it has long been taught, without a particle of real evidence, that the action of digitalis cannot be induced promptly. The whole range of digitalis action up to the maximum, that is, cardiac stoppage, can be induced within from five to fifteen seconds by the intravenous injection of digitalis tincture, deprived of its alcohol, or digitoxin. This simple experiment disposes forever of the mischievous claim that digitalis action is slow. The *effect* of therapeutic doses is *gradually* induced; the *action* is *immediate*. A bullet fired through the heart *acts* instantaneously; the *effect* is a fatal hemorrhage, the rapidity of which depends largely on the size of the wound. With suitable dosage, digitalis exerts its action in much less time than was formerly believed to be possible.

The action of an intravenous dose of strophanthin or ouabain is not so lasting as is that of a corresponding dose of digipuratum, but it lasts until it can be supplemented by the oral administration of digitalis.

Another fallacy that dies hard is that digitalis and digitoxin act on the vessels and cause high blood pressure, and that they are therefore contraindicated in cases in which the blood pressure is already high. This has been the greatest stumbling block in the way of the use of digitalis, next to that of regulation of dosage. Every one of the digitalis bodies acts on the vessels when enormous doses are passed directly into them, but this action is never induced by therapeutic doses. The contrary belief rests on the observation of the effects of massive doses in animal experimentation, and is not supported by any careful clinical observations or experiments with therapeutic doses.

Among the less important fallacies that have severally contributed to the distrust of digitalis and have been utilized by manufacturers to their own advantage, the following may be mentioned briefly: All drugs, preparations and active principles of this group without exception cause nausea and vomiting in overdoses through their action on the vomiting center in the medulla—not through any direct action on the stomach; hence it cannot be avoided by any mere change in the mode of administration, or mere choice of preparation, but only by proper regulation of the dosage—and by dosage I mean the amount which actually enters the blood stream and which alone can act on the heart.

None of the drugs of this group are actively diuretic through any direct action on the kidneys. They induce diuresis solely through an improved circulation. That does not mean either a higher or a lower blood pressure in every case; it means a more effective circulation, one better adapted to the needs of the individual patient. This sometimes means an increase, sometimes a decrease, in pressure.

All digitalis galenicals, tincture, infusion, extract and fluidextract, exert the same kind of action, because they all contain all of the active principles of the drug.

All digitalis bodies without exception have the disadvantage of being absorbed somewhat slowly and irregularly from the alimentary tract. Digitalis tincture, as well as the infusion and fluidextract, are absorbed *fairly* promptly; strophanthus and strophanthin, ouabain, convallaria preparations, apocynum preparations, and wahoo are absorbed very irregularly. This is of prime importance, because it requires the administration of large doses of these drugs in order to insure the therapeutic effects; but rapid absorption occurs occasionally under conditions that are not understood, and severe, or even fatal, poisoning may result. The latter drugs should never be used for oral administration.

There is no difficulty in getting standardized digitalis preparations, and these do not deteriorate rapidly. Slight deterioration is not important, because the drug must always be given until a definite action is induced, and this varies with every patient; since there is no fixed dose that is applicable to different patients.

Tincture of digitalis contains only traces of fat, and that is no more disturbing to the stomach than an equal amount of other fixed oils or fats.

Granted that a correct diagnosis has been made, digitalis therapy becomes largely a matter of correct dosage, including the proper method of administration, which is nearly always oral. It is beyond the scope of this paper to consider dosage and methods of administration in detail, the present purpose being to point out to the clinician the resources that he has at his command; but he will find valuable suggestions in the following papers:

"A Clinical Study of Crystalline Strophanthin," by Harold C. Bailey.[1] In this paper the author reports most careful clinical observations with crystalline ouabain, formerly called crystalline strophanthin.

"The Toxic Actions of Digitalis on the Heart," by the same author.[2] This is an excellent study of the toxic actions of digitalis that frequently escape attention.

"Digitalis Dosage," by Cary Eggleston.[3] This is perhaps the best recent study of the method of administering digitalis whereby prompt effects are induced after oral administration.

Fraenkel and others have published numerous papers dealing with the intravenous administration of strophanthin.

I am well aware that many readers will be inclined to deny many statements made in this brief article, but I can only assert that they are based on careful clinical and experimental observations and are not contradicted by any recent careful studies.

[This report was submitted in manuscript to Dr. Joseph L. Miller, Major, M. R. C., U. S. Army, Camp Dodge, Iowa, and Dr. Miller writes: "I agree fully with all the statements made by Dr. Hatcher. He has expressed exactly my views on this subject."

Dr. Richard Weil, New York, writes: "I have not only been familiar for some years with the work done in Dr. Hatcher's laboratory on the digitalis drugs, but have made practical application of much of it in my service in Mount Sinai Hospital with gratifying results. I can therefore express myself as in full agreement with the suggestions made in the present paper."—Ed.]

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

PARAFFIN FOR FILMS (SURGICAL PARAFFIN, PLASTIC PARAFFIN)

Paraffin intended for application to burns, etc., should be solid at body temperature, but be more ductile and pliable than the official paraffin (Paraffinum, U. S. P.) and be liquid at or below 50 C. A thin film when prepared and tested as described below should be pliable at or below 28 C. and ductile at or below 31 C. At body temperature (38 C.) it should be pliable, and adhere to, but permitting ready detachment from the skin.

Actions and Uses.—Paraffin for films acts mechanically. When applied to burns and denuded surfaces, it provides an air-excluding dressing which relieves pain, forming a soft, pliable splint-like covering to the wounded surfaces, keeps the parts at a relatively uniform temperature, immobilizes the epidermal tissue, and may aid in the formation of new tissue by acting as a scaffolding for newly formed cells.

Paraffin for films is used mainly in the treatment of burns. It is said to be useful in the treatment of "frostbite," "chilblains," and for covering denuded surfaces. It is also employed to prepare "paraffin-covered bandages" and to seal gauze dressings.

Dosage.—In the paraffin treatment of burns the wound, after preparatory treatment, is dried and a thin coating of either liquid petrolatum or melted paraffin for films (at a temperature of about 53 C.) is applied by means of an atomizer or brush. This is followed by the application of a thin layer of cotton and then another layer of the melted paraffin; the dressing is finished by covering with cotton and bandaging.

The melting point of paraffin for films is determined by the method of the U. S. Pharmacopoeia, IX, p. 596.

The pliability and ductility of paraffin is determined as follows: A little of the melted substance is poured on water having a temperature of about 40 C. so as to form a number of separate films. The temperature of the bath is then gradually lowered by the addition of cold water to determine the pliability and ductility. (Pliability test). The film while immersed in water is doubled on itself and the temperature of the water observed at which the film breaks sharply on *one* fold. (Ductility test.) The film is stretched while under water and the temperature of the water noted at which the film breaks sharply and evenly.

A small surface of the forearm is painted with melted paraffin, covered with a thin layer of cotton, another coat of paraffin painted on the cotton, and then dressed with cotton and bandage. After one hour, the film should remain attached to the skin, showing it is adherent, but be easily removable.

STANOLIND SURGICAL WAX—A brand of paraffin for films, melting at 47 C., being pliable at or below 25 C. and ductile at or below 29 C.

Actions, Uses and Dosage.—See under general article on Paraffin for Films.

Manufactured by the Standard Oil Company of Indiana, Chicago.

VITAMINS AND TUMOR GROWTH

Tumors in general and cancers in particular are tissues growing under special conditions. A comparison between the laws determining tumor and tissue growth will determine our knowledge of the physiology of tumors as well as of tissues. There exist similarities and analogies in the behavior of both, and there are differences either real or due to a gap in our knowledge. The differences will suggest new problems. These were the statements made by Leo Loeb of St. Louis at a symposium on cancer before the Section of Experimental Medicine of the American Association for the Advancement of Science in New York, last December.[1] It has come to be recognized in recent years that normal growth is dependent on a number of nutritive factors, the importance of which is only beginning to be understood. Thus for the purpose of growth a diet may be deficient with respect to both the quantity and the quality of its protein, to its inorganic salts, or to its total calorific content; but beside an adequate quota of these components, there is recognized the necessity of certain as yet unidentified substances now popularly known as vitamins.

So far as known at present, the vitamins which are essential to growth, and without which life cannot even be maintained over a reasonably long period, are furnished to the organism with the diet. They do not seem to be produced de novo in the animal body. Benedict and Rahe[2] have accordingly investigated the question whether tumor cells, like somatic cells, are dependent on a supply of vitamins from outside sources, or whether tumor cells possess a power of synthesis of vitamins. If the latter supposition should be correct, then, the investigators state, we should have a fundamental difference between tumor and body cells, a difference as great in this respect as between plant and animal cells. The former of these synthesize vitamins; the latter have never been shown to do so. If tumor cells possess the power of vitamin synthesis, then they have indeed a unique and tremendous advantage over ordinary tissue cells.

Obviously, as Benedict and Rahe further remark, this question is an important one worthy of detailed study. The relation of diet to the growth of tumors has frequently been investigated in the past. The novelty in these new researches consisted in comparing the growth of the same strain of tumor in experimental animals, in the diet of which, in one group, no more vitamin was supplied than was necessary barely to maintain the animals without growth, whereas, in the other group, the ration was sufficiently rich in vitamin to facilitate liberal growth. The authors argue that, if on the diet deficient in vitamins the animal plus the tumor increases in weight, approximately in accordance with the weight of the tumor, it is obvious that the latter tissue is independent of an outside source of vitamin so far as its growth is concerned, since a quantity of vitamins is supplied in the food that will suffice for the maintenance only of the animal's original tissues. If, on the contrary, the tumor grows, but the total weight of the animal plus the tumor remains unaltered, then we are justified in concluding that the tumor is dependent on vitamin from outside sources, and that, through increased avidity, it is able to appropriate the vitamins of the host's tissues to its own uses, so that a given quantity of the host's tissue is practically transformed into tumor tissue. In this event there would be no appreciable change in weight in the animal, though the tumor might conceivably grow to a considerable size before the death of the host. Another possibility would be that during the growth of the tumor, the weight of the animal would increase more rapidly than could be accounted for by the growth of the tumor. In this instance we should have to assume that the tumor produced a growth-promoting substance that escaped into the circulation and affected the growth of the host.

The animals on both groups of diets—those comparatively deficient in vitamins as well as those richer in these substances—readily developed tumors after appropriate inoculations. But, on the vitamin-restricted diets, the total weight of the animals failed to exhibit any increase, despite the development of tumors equivalent to about one third of the total body weight. The very rapid growth of tumors under conditions that completely prevent the growth of body tissue indicates the remarkable avidity that tumor cells may show. Benedict and Rahe tentatively assume that tumors, like the somatic cells, are thus dependent on growth stimulants from outside sources, either from the food or from the tissues of the host. Their experiments show, furthermore, that even a very rapidly growing experimental neoplasm does not liberate into the circulation any substance that may act as a stimulant to body growth in the absence of growth-promoting vitamins in the diet.

THE HUNGRY INFANT

The problems of alimentation in infancy have been greatly delayed in their solution because of a lack of objective signs and accurately established facts on which rational procedure can be based. In the adult, the subjective symptoms can be consulted; and the progress in the expert analysis of the physiologic and chemical functions has reached a stage of considerable precision. Hunger and appetite, the responses of the digestive glands to various types of stimuli, the movements of the successive segments of the gastro-enteric tract, and other factors are now understood with considerable accuracy.

It requires little argument to indicate the difficulties that beset the student of the comparable questions in the case of the infant, in which the personal factor of cooperative intelligence is lacking and the technical hindrances to experimentation or instrumentation are obviously great. Yet certain items of information are plainly needed in the routine of infant feeding. It is important, for example, to have a defensible basis on which to determine the periods between the successive administration of food, or to know whether difficulties in nursing have an alimentary background, so to speak. Two years ago, Carlson and Ginsburg[1] made a noteworthy contribution to the analysis of the hunger sense in the new-born by actually demonstrating the hunger contractions of the stomach in these infants. It was thus shown that, as in adults, contractions of the empty stomach cause the hunger sensation, but occur with even greater intensity in infants. The "pangs of hunger" are associated with the rhythmic contractions of the stomach wall. As one writer has expressed it, impulses set up by these contractions and carried to the higher centers are, in the normal consciousness, recognized as hunger. These impulses produce secondary effects, such as restlessness and irritability. However, he adds, the prime factor in the desire for food depends not on the basis of distress due to the contractions of a hollow viscus, but on "the memory processes of past experience with palatable foods." This psychic factor is appetite, and its absolute distinction from the physical factor, hunger, must be kept in mind.

The studies of Carlson[2] and his co-workers have been corroborated in the Department of Pediatrics at the University of Minnesota by Taylor,[3] who has further shown that still greater hunger contractions occur in the stomachs of the prematurely born. In the adult, in general, the taste of salt, sour, bitter or sweet, or the chewing of agreeable, disagreeable or indifferent substances all produce temporary inhibition of the gastric contractions. The chewing of palatable foods by the adult when hungry causes an inhibition, made more lasting by the flow of appetite juice in the stomach. Local stimulation in the mouth is almost invariably inhibitory. Food in the stomach likewise stops the hunger contractions, this form of inhibition being less transitory than that from the mouth. Taylor[3] has now found that inhibition of the hunger contractions from the mouth does not occur in young infants. Inhibition of the hunger contractions from the mouth in older infants is present only as the result of stimuli that the babe has learned to associate with food. It does not occur with substances which produce equally strong sensory impressions but are not considered by the infant as food. Inhibition from the mouth is psychic in character. On the other hand, reflex inhibition from the presence of food in the stomach is present in infants of all ages, though it may be developed only partially in young infants.

There is a widespread belief that the crying infant is hungry. Taylor has expressed the view that hunger is not an immediate cause of crying in a normally developing breast-fed baby, so long as the periods between feedings are not unduly protracted. In his own words, neither the hunger contractions themselves nor the increased irritability due to them are ordinarily immediate factors in the production of crying. Young infants sleep throughout strong contraction periods. Older infants often do the same, and are frequently quiet even from twelve to sixteen hours after a feeding. Mental factors produce crying at a very early age. And the fact that crying ceases when food or water is administered may mean only that the infant's attention is diverted to the performance of a pleasurable act.

Some time ago, Ginsburg, Tumpowsky and Carlson[4] reported the average time between nursing and the appearance of hunger contractions to be two hours and forty minutes, with a minimum of two hours and twenty minutes, and a maximum of three hours and thirty minutes. Under like conditions, Taylor has observed that the average time required for the development of hunger in healthy infants gaining in weight and receiving a known sufficient amount of food is, in premature infants under 1 month, one hour and forty minutes, with a maximum of two hours and twenty minutes and a minimum of forty minutes; in full term infants under 2 weeks, two hours and fifty minutes, with a maximum of four hours and a minimum of two hours; and in infants from 2 weeks to 4 months, three hours and forty minutes, with a maximum of four hours and thirty-five minutes and a minimum of three hours and twelve minutes.

One might be inclined to utilize these data in determining the ideal interval that should elapse between feedings. It appears, however, that it is only in normal babies, receiving well tolerated food in sufficient quantity, that the development of hunger waits on the emptying of the stomach. In the case of infants with chronic disturbances of alimentation, hunger contractions may occur long before the stomach is emptied. Consequently, Taylor remarks, their presence is not in itself an indication that the stomach is ready for food. Another current view that has been upset by further observations of Taylor[5] concerns the response of the secretory apparatus of the stomach to the process of feeding. Contrary to what has been found in adults, there is no appetite or psychic secretion of gastric juice in the young infant.

THE VITAL CAPACITY OF THE LUNGS—ITS SIGNIFICANCE IN DISEASE

The vital capacity of the lungs is the expression applied to the volume of air that can be expired after the deepest possible inspiration. Among the factors affecting the vital capacity are the age, sex, height, weight, the size and flexibility of the thorax, and the state of physical training of the individual. Recent measurements made at the medical clinic of the Peter Bent Brigham Hospital in Boston furnish the following standards for the vital capacity of the lungs of normal men: for men over 6 feet tall, 5,100 c.c.; between 5 feet 8½ inches and 6 feet, 4,800 c.c.; between 5 feet 3 inches and 5 feet 8½ inches, 4,000 c.c. In women of the same heights it is about one fifth less. When compared with these standards, the vital capacity of healthy persons very rarely falls below 90 per cent. of the normal standard, although it may rise considerably above the normal. According to the Boston data, the most important factor inducing extreme variation in the vital capacity of normal subjects of similar size appears to be athletic training. The average vital capacity of ten highly trained athletes was 120 per cent. of the normal standards. The increase of vital capacity had persisted in some of them for several years after strenuous exercise had been last indulged in.

Although this feature of respiration has been measured in literally thousands of persons, the determination of its magnitude has found a limited application at best in relation to pathologic conditions. Peabody and Wentworth[6] at the Harvard Medical School have found, in a study of a variety of diseases, that the tendency to dyspnea corresponds closely to a decrease in the vital capacity of the lungs. This is not true of the anemias; and in diseases in which dyspnea is not a prominent symptom the vital capacity is usually within the normal limits, although general weakness and old age may cause a slight decrease. Patients with heart disease afford the typical illustrations of the close relation between the vital capacity and dyspnea. Peabody points out that the essential difference between normal subjects and patients with heart disease with regard to the production of dyspnea is not that cardiac patients are necessarily more sensitive to any given stimulus to the respiratory center, but that they cannot stand so *great a stimulus.* Cardiac patients become dyspneic easier than normal subjects because they are unable *to meet the rising stimulus to respiration* with an adequate increase of pulmonary ventilation. The limitation of the depth of breathing is thus an important factor in the production of dyspnea in patients with heart disease.

Peabody and Wentworth have found further that compensated patients, who do not complain of dyspnea on exertion, have a normal vital capacity. Patients with more serious disease, in whom dyspnea is a prominent symptom, have a low vital capacity, and the decrease in vital capacity runs parallel to the clinical condition. Changes in the clinical condition are usually associated with changes in the vital capacity. As a patient improves, his vital capacity tends to rise, and as he becomes worse, it tends to fall.

Among the obvious causes of decrease in vital capacity are pleural effusion, emphysema and ascites. The distention of the pulmonary vessels, owing to an insufficiency of the heart, has also been suggested. If this is true, then, as Peabody and Wentworth propose, the determination of the vital capacity of the lungs may be of value as an early sign of cardiac weakness. Finally, in giving quantitative information as to the tendency to dyspnea, such estimations have a practical value and incidentally give some indication of the actual clinical condition and reserve power of the patient.

FACTORS AFFECTING THE GERM CONTENT OF MILK

As we have stated before, the modern demand for sanitary milk of a higher grade inevitably involves an increased expenditure in labor and equipment appropriate to bring about the desired results. In the interests of economy, it is imperative, therefore, to provide dependable information regarding those factors which are especially responsible for the supply of satisfactorily clean and wholesome milk. Obviously, it would be an extravagant folly to incur unnecessary expense in connection with items that cannot at best contribute anything to the improvement of the milk supply; whereas every effort must be made to safeguard a food as important as is milk, at every step in its production, whenever the possibility of deterioration unquestionably exists.

The quality of milk from the sanitary standpoint is at present judged essentially on the basis of its chemical composition and its germ content. The latter in particular has come to be regarded as an index of cleanliness and wholesomeness. The limit of bacterial contamination permissible has been fixed by law in many communities. Says Professor Harding of the University of Illinois:

---

[5] Taylor, Rood: Hunger and Appetite Secretion of Gastric Juice in Infants' Stomachs, Am. Jour. Dis. Child., October, 1917, p. 258.

[6] Peabody, F. W.: Clinical Studies on the Respiration, III, A Mechanical Factor in the Production of Dyspnea in Patients with Cardiac Disease, Arch. Int. Med., September, 1917, p. 433. Peabody, F. W., and Wentworth, J. A.: Clinical Studies of the Respiration, IV, The Vital Capacity of the Lungs and Its Relation to Dyspnea, ibid., p. 443.

> No matter what is our personal judgment regarding the wisdom of such bacterial standards, the legally constituted authorities having thus established these limits of bacterial content, the burden rests on the producer and the retailer to observe them. When adjusting their business methods to such variable limits as those mentioned above, it is important that the dairymen have fairly accurate knowledge of the relative importance of the various dairy operations upon the germ content of the milk.

It is widely believed and insisted on for the guidance of dairymen that the construction and condition of the cow stable plays a very important part in the production of sanitary milk. The ubiquitous inspector is continually emphasizing the influence of barn conditions, so that large expenditures are continually being made by dairy farmers to meet the supposed necessities for securing recognition in the retail market. These features obviously cannot fail to add more or less to the item of cost in the production of milk—an item which should be cheerfully borne by the consumer if the expenditure is fully justified. It is surprising, therefore, to learn from investigations made in a large number of ordinary dairy barns by two of our prominent experiment stations that, when the influence of the utensils employed is excluded, the dairy barns themselves exert little measurable influence on the germ content of the milk.[1] Perhaps too little attention has been paid in the past to the utensils as a source of contamination. Competent dairy bacteriologists now tell us that, even under wide extremes in barn conditions, it is possible to produce milk with a germ content of less than 10,000 bacteria per cubic centimeter when the utensils are properly prepared.

Harding remarks that the mistaken impression respecting the relative importance of barn conditions in connection with germs in milk should not be taken as a criticism of health officials. Such officers are charged with the protection of the public health. When the facts are available, they utilize them. When exact information is lacking, they must proceed in accordance with their best judgment even though they recognize the fallibility of such judgment. Furthermore, as Prucha and Weeter[1] remark, this result must not be construed as a defense of dirty barns. They simply point to the fact that the large numbers of bacteria commonly found in milk do not have their origin in the barn. The findings of these recent investigations, substantiated by a series of independent investigations, cannot fail to be helpful to sanitary authorities, and may serve to readjust certain unnecessary economic burdens.

THE COMPOSITION OF MILK FATS

The ordinary fats are regarded by chemists as glycerids; that is, compounds of glycerol (glycerin) and fatty acids. It must be borne in mind that as they occur in nature the fats and oils are never single chemical substances; indeed, they are seldom composed entirely of glycerids. Just as up to only a few years ago the proteins of nature were commonly considered as a class in their biologic functions, and distinctions between different types of proteins were rarely if ever made in a physiologic sense, so fats have until the present time been dealt with groupwise in practically all considerations of their nutrient or biologic significance. We know today, however, that the rôle of individual proteins in the organism depends on their digestibility and on the character of the amino-acids which they can yield. Certain of the amino-acids, like tryptophan, seem to be far more indispensable, for instance, than others like glycocoll, so far as their production from the dietary proteins is concerned.

May not some similar point of view be applicable to that somewhat heterogeneous group of glycerids known as fats? In any fat or oil there is a mixture of several glycerids, with varying quantities of cholesterol or substances related to it, and often free fatty acids or soaps as well. These considerations, Leathes[1] remarks, show that the number of compounds of fatty acids which have to be dealt with in biologic chemistry, and for which we have no single comprehensive name, is very large; and also that the precise constitution of any one such compound may, even when it is not complicated by the presence of phosphoric acid, be difficult to determine; whereas, when this complication does exist, the difficulty is bound to be greatly increased. In fact, at present these more complicated compounds of the fatty acids are among the most obscure of those with which animal or vegetable chemistry has to deal, more obscure and indefinite even than many of the proteins in human diet.

Evidently, in the case of the fats, the first point of attack in the move toward progress must consist in a better understanding of the nature and proportions of their constituent fatty acid groups. And no fats appear to be more worthy of elaborate analysis and study than those which go to make up part of milk, the prototype of perfect foods. The glycerids of a very large number of fatty acids occur in nature, and the possibilities of their mixtures and combinations must consequently be manifold. We can only agree with a recent student of the subject who remarked that no problem presents greater difficulties to the analyst than the quantitative separation and determination of a mixture of fatty acids, and the acme of difficulty is reached in the case of the most complicated mixture of fatty acids which is found in butter fat. For this reason, investigators have mostly been content to limit their attention to the determination of various more or less well defined groups of acids, such as steam-volatile, or water-soluble, or unsaturated acids, etc., whereby naturally only a very imperfect record of the variations in composition has been obtained by the research to date.

---

[1] Leathes, J. B.: The Fats, London, 1913.

In a general way it has, of course, long been known that the mixture of glycerids of the fatty acids occurring in milk, and spoken of as butter fat, differs conspicuously from the other fats likewise rich in olein, palmitin and stearin by yielding more butyric acid (the volatile acid to which the odor of rancid butter is said largely to be due) and less stearic acid than other food fats. We heartily welcome, as a conspicuous step in advance, the investigation of the distribution of the fatty acids in the milk fat of the cow and the sheep, carried on by Crowther and Hynd[2] in the Institute for Research in Animal Nutrition at the University Department of Agriculture, Leeds, England. They state that there is clear evidence that the only acids present in more than minimal proportions are the unsaturated acid, oleic acid, and the eight saturated acids of the acetic series, representing the members with an even number of carbon atoms from C_4 to C_{18}, namely, butyric, caproic, caprylic, capric, lauric, myristic, palmitic and stearic acids.

The new values for butyric acid (4.3 per cent. for cow's milk fat and 6.5 for sheep's milk fat) are higher than those usually given. The presence of a very considerable content of lauric acid (about 5 per cent.) was firmly established, so that, as the English investigators state, the usually accepted idea that only traces of lauric acid are present in butter fat must be modified. They further find that palmitic acid is present in much smaller proportions than usually assumed, while myristic acid is more abundant. The content of stearic acid, regarding which there has likewise been considerable debate, was found to be 3.4 per cent. for cow's butter fat and 4.4 for that of the sheep. About two fifths of the total fatty acids consist of oleic acid.

The more precise appreciation of the nature and quantities of these various fatty acid groups which can be liberated by the digestive processes for absorption from milk, cream or butter may pave the way for a better understanding of the rôle of fats in the economy. In any event, the complex mixture conventionally termed "fat" is revealed in the case of the milk product as a source of a considerable number of definite compounds. Thus the relation of fats to their antecedents in metabolism, the precise mode of the degradation of fats when they furnish energy to the body, and the origin of intermediate stages of fat catabolism which sometimes crop out as pathologic products—these and other problems come appreciably nearer to an intelligent solution when the substrate involved is clearly understood.

Current Comment

MEDICAL RESERVE OFFICERS AND ORDERS TO ACTIVE DUTY

"How soon shall I be called on to report for active duty?" This question and the uncertainty of its answer has been probably the most trying experience of the civilian physician who has accepted a commission in the Medical Reserve Corps. This uncertainty began on the day on which the commission was accepted because on that day the newly made medical officer realized that he had become subject to call, and must be ready to respond. There was a time in the early weeks of the war when medical reserve officers were ordered out on very short notice, often giving them only one or two days in which to close up their personal affairs. Some physicians, aware of this condition, even gave up their offices, practically closed their business, or made arrangements which they would not have made had they not presumed that they would be ordered out very shortly. These emergency conditions have now passed. No such uncertainty rests on the man who accepts a commission today, for the Surgeon-General's Office has announced that members of the Medical Reserve Corps will be given at least fifteen days' notice before being ordered into active duty. It is quite possible that even more than fifteen days will be given those who require more time in which to arrange their affairs.

THE NEW YORK CATSKILL WATER SUPPLY

The formal dedication, October 12, of the great Catskill aqueduct should not pass without notice in these days of absorption in warlike activities. It is not a question merely of the gigantic features of the undertaking from an engineering standpoint: a storage reservoir that can hold 132,000,000,000 gallons of water; an aqueduct 120 miles long starting at 610 feet above tide line and dropping to 1,114 feet below sea level when it passes under the Hudson River; a delivery capacity of 500,000,000 gallons daily; the cost to date of about $140,000,000; there is also the fact that this greatest of all water systems supplies a water probably as pure and free from all liability to produce disease as any in the world. The best expert advice in the country on sanitation has been obtained and acted on. A carefully prepared and controlled watershed, full utilization of the natural purification effected by extensive storage, filtration, aeration and chlorination have all been brought into play to create a high degree of safety and potability. No stone has been left unturned to make the new Catskill supply, what it probably really is, the best large water supply in the world. It is pleasant to learn that the whole undertaking has been carried out in a spirit of the highest citizenship.

"The construction of the Catskill aqueduct, covering a period of ten years, affords a model of honest, clean and efficient municipal government in which every citizen should take pride. It is being finished within the original estimate of expense, and is a commendable example of municipal economy. It has been completed within contract time, without a labor strike, and is a tribute alike to the commission which directed the work, the contractors who carried it out, and the workmen who labored faithfully to build it. In its inception it was fostered by citizen bodies having the public interests at heart, and in its execution it had their invaluable support. It is a testimony of what disinterested civic spirit in cooperation with faithful public officials can accomplish."[1]

The *Engineering News-Record*, Oct. 11, 1917, has this to say:

> Among the great dams of the world now stand, as a result of the water board's work, the Ashokan and the Kensico. The Hudson River and the Narrows siphons are the only two of their kind, while the many miles of aqueduct—in tunnel, cut-and-cover and steel pipe siphon—are without precedent, capacity and length both considered, in water-works records. All of this work, involving an expenditure of millions, has been kept free from suspicion of the honesty of any one connected with it, and from ugly controversy about the capability of the designers or the quality of the work; and this in a city where political contests have been fought bitterly, and where many efficient heads have been removed because principles were upheld. The engineering bureau has kept out the inefficient; has successfully resisted the onslaughts of those who might have sought improper advantage, and has given to the city a set of structures which experts have pronounced excellent in the highest degree.

"THE BASE HOSPITAL AND THE ICE MACHINE"

Some months ago, under the above title, we commented on the fact that one local Red Cross organization had refused to approve the appropriation of money for the purchase of an ice machine by a base hospital. The directors could see little use for an ice machine as part of the equipment of a base hospital. Now, far be it from us to take the credit through that little comment for the sequel, but it is very interesting to note in the *Official Bulletin* for Wednesday, October 24, that the Red Cross War Council has appropriated $70,200 for ten portable ice making plants for use in connection with the Red Cross base hospitals in France. The appropriation was made at the request of the American Red Cross Commission to Europe. So the base hospitals will now have their ice machines.

DEATH OF REVERE OSLER

In announcing the death of Sir William Osler's only son in the issue for September 8, The Journal stated that Revere Osler had been wounded while on active duty in France, and was taken to England for treatment, where he died. Recently Dr. D. L. Moore of Columbus, Ohio, sent to The Journal a quotation from a letter dated September 21 written by a nurse in one of the American hospital units in France. She said: "One of the saddest things that happened during our stay in Belgium was the death of Sir William Osler's only son. He was brought to our station one night with a bad chest wound, a perforating wound in the intestines, and an injured thigh. Drs. Brewer and Darracks got Dr. Crile, who was in a station back of us, and also Dr. Harvey Cushing, who was near, in consultation. Major Darracks, with whom I worked, did the operating, Major Brewer assisting, Dr. Crile giving a direct blood transfusion, and Dr. Cushing consulting generally. Everything was done that could have been done in any hospital, but the boy died several hours later. He was in the Royal Field Artillery service." A letter has just been received from Sir William Osler, dated Oxford, October 7, from which we quote: "My son Edward Revere was wounded in the chest and abdomen by a shell August 29, was taken to the Casualty Clearing Station, at which my good friends George Brewer of New York, and George Crile were stationed. Darrack of New York operated and Crile transfused. His life-long friend Harvey Cushing was also with him. Everything possible was done, but he died about twenty hours later. Many of my friends would be glad to know of this." It is gratifying to the thousands of American friends of Sir William Osler that when his son was mortally wounded the best medical and surgical skill was available, and especially that this skill rested in old-time American friends of both the father and the son.

BACTERIA AND VITAMINS

It is evident, Lusk writes, that the science of nutrition includes something more than the production of energy from fat, carbohydrate and protein. There must be certain salts and certain qualities of protein in the diet, and there must be minute amounts of vitamins. The food hormones, which are present in small amounts in various natural foods of both animal and vegetable origin, are essential to "the harmonious correlation of the nutritive functions." They have already entered into the popular literature of nutrition. This is highly appropriate; for although these as yet unidentified components of the diet are present in very small amount in most foods, healthy life seems to be impossible for any considerable time without them. Even among plants, with their large synthetic powers, growth seems to be influenced by factors similar to the food hormones of animal nutrition, if one may judge from the researches of Bottomley in England. He believes that vitamins or comparable hormones may be destined to play an important part in the cultivation of vegetable foodstuffs. And now come the bacteria to claim the need of such hormones. In an investigation on the chemical factors involved in the growth of the meningococcus, conducted at Cambridge by Dr. Dorothy Lloyd,[1] the vitamins have found recognition. We are told that the primary cultivation of the meningococcus in vitro is possible only in the presence of certain accessory growth factors (the so-called vitamins) present in blood, serum, milk and other animal fluids, and probably present also in vegetable tissues. These accessory substances are described as substances that are moderately heat stable. The vitamins are not the sole feature leading to success in cultures. The presence of suitable amino-acids is equally important; but these have already begun to be recognized as the appropriate bacterial pabulum.

---

Medical Mobilization and the War

NEWS FROM A FOREIGN BASE HOSPITAL

U. S. Army Base Hospital No. 3 (Harper, Detroit)

Major Angus McLean, director of Base Hospital No. 17, Harper Hospital, Detroit, now United States Army Hospital No. 3, writes from France: "We have a fine hospital here of 600 beds, and are enlarging it to a 1,200 bed hospital. The hospital is located in the vicinity of the American troops. There are about fifty American patients here now. The following is a list of our staff as at present constituted: director, Angus McLean; assistant directors, Majors P. M. Hickey, H. N. Torrey, and George E. McKean; Capts. L. G. Hirschman, E. C. Cullen, Rolland Parmeter, W. D. Ford, Robert Owen, James Breakey, John C. Dodds, William E. Spitzley, A. Stirling, Alfred LaFerte, T. K. Gruber; Lieuts. Duncan Campbell, E. J. O'Brien, Fred Buesser, C. B. Lockwood, B. H. Larson, B. B. Belt, L. J. Cushman, H. Gregory; dentists, Earl Barkley and William T. Shannon."

PATRIOTIC PHYSICIANS OF MURPHYSBORO

Dr. Charles Molz of Murphysboro, Ill., writes that Murphysboro is a city of 9,000 people, and that of the seventeen physicians in the city, thirteen have taken the examination for the Medical Reserve Corps. Of the remaining four, two were too old, one a lady, and the other was physically disqualified. Of the thirteen physicians who applied, nine were accepted and four were rejected. Six of the nine are now on active duty.

UNITED STATES DENTAL SCHOOL IN PHILADELPHIA

Announcement is made that the Surgeon-General has ordered the establishment in Philadelphia of a school for training in oral surgery and plastic reconstruction of the face and jaws of men who have been maimed in the war. Twenty-five or thirty recently appointed officers of the medical reserve service will be detailed for didactic and laboratory study at the institution. Dr. Wilmer Krusen, director of public health and charities, has agreed to afford facilities in the dental wards of the Philadelphia General Hospital for clinical demonstrations, and has offered his office in city hall for meetings of the teaching board. Dr. Charles R. Turner, dean of the Evans Institute of Dental Surgery, will have charge of the organization of the teaching staff. He will be assisted by Dr. Herman Prinz of the institute in selecting the staff. Lecturers and operators from other medical and dental schools of Philadelphia, who are specialists in oral surgery, will become members of the staff.

NEWS OF THE TRAINING CAMPS

At Fort Riley

The campaign for the sale of liberty bonds in the Medical Officers' Training Camp at Fort Riley was a marked success. Six hundred and eighty-seven medical officers subscribed for a total of $95,000; the total for the camp was $213,000, an average of $73 per man. The total for the post was $6,000,000.

Equitation at *Fort Benjamin* Harrison

The real meaning for the concentration of energy in the training camps for medical officers is beginning to come to the surface. Physical conditioning has been in progress from the first, and still continues. How necessary it is to "be fit" is best evidenced by the test of endurance needed for "equitation," for "periods in the trenches," for "gas mask exercise," and for all the advanced military work now in progress. Very few of the doctors before the training in "setting up exercises" and the "fours right" and "fours left" drills could have stood up under the fatiguing work of the present.

At the medical officers' training camp at this post the A. B. C.'s have been well learned, and the actual work needed in campaign, as developed by the present war, is well under way. Not the least of this is horsemanship.

You may wonder at this assertion, believing, as do many, that cavalry no longer is needed. Even though cavalry is not conspicuous at present, it still exists, and must have medical officers attached to its units. Likewise, in the artillery, only the heavy type of gun is moved by motor. Most of the guns are horse-drawn, and those artillerymen who do not ride on the guns go horseback. Thus, here, too, the regimental surgeons must know how to ride. As a matter of fact, all surgeons in the Army are classified as mounted officers, and, therefore, must know the essentials of horseback riding. Not only is it necessary for the medical officer to be able to "stick on" an ordinary horse, but he must be familiar with the art of the care of the horse, and blanketing, saddling and bridling must be mastered.

The students on duty here have a most excellent advantage in this connection. It happens that there are a goodly number of fair horses for our use, and, better still, both the instructor and his assistant are expert horsemen. Hence, equitation, a part of the course which all must take, finally becomes a pleasure.

"You may think it is fun to teach civilian physicians to sit and stick on horseback; it is *not*." That was the remark of the assistant teacher in equitation when I asked him what he thought of his job. An active cavalry officer for seven years, but now a physician and medical officer, he felt the responsibility that rested on him, yet his natural humor was expressed when he remarked, "I cannot but think vividly of Don Quixote and his Rosinante when I see the equitating medicos."

All joking aside, here is what is actually being undertaken and accomplished: Under the supervision and tutorship of Major H. McC. Snyder, M. C., U. S. Army, himself a most accomplished horseman, and his assistant, Lieut. V. C. von Unruh, M. R. C., U. S. Army, who served as a cavalry officer for seven years in one of the European armies, the doctors are taken out for lessons in horseback riding from 1 to 5 o'clock every afternoon. At the picket line they find 130 horses standing, waiting in awe, and most assuredly in humor, for of this horses possess an abundance. Here the doctors are taught to fold the saddle blanket, to put it on the horse's back, to put on the saddle, tighten the cinch, measure the proper length of stirrups, and bridle their mounts. Next comes the difficult task of mounting, which feat must be mastered before the ride begins. Mounting inside the picket line is forbidden, and the horses must be "led out" to the line that forms for the start of the ride. When at last, after many trials and tribulations, with fractious horses loath to leave their feed boxes, the embryo cowboys are in line, the critical eyes of teacher and assistant inspect the squad. Here a blanket is put on wrong side out. "Unsaddle and put it on right" is the order. There a cinch is artistically woven with a beautiful figure-of-eight between the rings—truly a testimony to this surgeon's accomplishment in bandaging. Off must come that cinch, and on it must go correctly and quickly—mayhap, against the loud protestations of the doctor, who has "saddled a hundred horses," and thinks that the cavalry drill regulations may be improved vastly by his wise and valuable suggestions. Some cinches have been drawn so tight that the poor horse, when the doctor mounts, feels a constricting shortness of wind and there is a bolt and a kick, a jump and a lunge, and the poor "doc" kisses the sod, not from choice, but of sheer necessity. The saddle of another is so loosely cinched that, on mounting, the reserve corps surgeon gives a clear exhibition of "reversion to type." The saddle slides down on the left side of the horse, and the lieutenant or captain, or perhaps the major, hangs nervously holding on to pommel, saddle, stirrup and reins. You could not tell, on a bet, whether that struggling mass of living tissue was a doctor or his quadrumanous prototype of man.

When some eager enthusiast forgets to keep off the horse until the order to mount is given, he is usually taught his lesson by the horse, which sticks to the line like glue and refuses to advance. Instead of responding to the rider's "clucks," he bolts, rears and kicks until Mr. Caballera becomes detached from his *Equus caballus*. All that is left in such an emergency is to regain possession of that homeloving critter and "lead out," amidst the jeers of the waiting line of horsemen.

"Prepare to mount," "Mount" is commanded. All except three doctors manage somehow to climb to the Olympian heights of their saddles. Three unfortunates, however, now perform a veritable rococco minuet with their horses, circling around and around, *vis-à-vis* and *dos-à-dos*, until some kind orderly helps to hold the mount, and at last the seat is gained. "To have and to hold," the poet said—and this same thought was mine when I saw how easily a medico will part from his horse—almost as easily as the proverbial man from his money.

"Forward—March," and the squad moves on to the practice grounds, there to be divided into groups of from twelve to fifteen men, so that each may receive individual instruction in the use of thigh, knee, stirrups, reins and last, but not least, of the glutei. Some of the latter get "burned" because of stirrups too short, and many are the complaints on the following day. The lessons continue, however, and so do the "burns." Once a "burned one" was sent home, and on reaching the picket line a commiserating soul asked, "What's the matter, Doctor?" "Well, Doctor, you see, it's this way: My blisters broke, and so I had to come home."

The initial exercises mastered, the squad goes out for a cross-country ride—aye, more than this—to jump ditches and hurdles! All goes according to program, until some captain's horse bolts and races wildly for home, at a furious gallop, with half the squad following helplessly in his wake. No pullying on reins, no "Whoa, boy," no bracing hard in stirrups is of any avail. Mr. Horse has seen the leader's example, and now has his nose homeward set. Off they go like the phantom hunt, even the hounds at their sides gathering from along the roadway as the wild chase passes on.

On some other occasion a "medic" approaches the teacher with a broad smile hiding his face: "Oh, I can ride quite well, I've been on horseback all my life." (And he is 50 now.) Teachers are wise to such presumptuous assertions, and, of course, delight in giving this kind a special opportunity to prove his claims. When, a little while later, the command comes: "Gallop—March," Mr. Wise Horseman's arms flop like an eagle's wings, and his glutei imitate the steam engine's piston-head. Ah, yes, such "physical sitting-up" exercises do prove painful from more than one point of observation.

However exhilarating and fascinating the trip may have been, much of the joy evaporates when, on arriving back at the picket line, the order goes out to dry your horse with straw and, when dry, curry and brush him clean. How the ambitious rider now wishes he had curbed his desire for that last gallop which started the sweat on his horse. The horse, however, must be dried and cleaned, and, with firm resolves to stick to a walk as long as possible on the next ride, the doctors get back to camp to satisfy their ravenous appetites.

After all is said and done, our "medics" really like horseback riding. When their temerity has been subdued, and they have become accustomed to horse and saddle, they make quite a different picture. At the end of the four weeks' course in this work, although not expert horsemen, the students have learned how to ride.

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

The camp is undergoing an epidemic of measles. Every regiment brought in measles, and in some the disease has spread until several hundred cases have occurred. But three cases have been followed by pneumonia, and in no case has death or any serious permanent result followed.

Thirty-three cases of pneumonia have occurred in this camp with but one death. A careful, detailed record is kept of every case with the hope and expectation that tabulation and study of these cases will throw much light on this fatal disease.

Colonel Duncan spoke at a meeting of the Chamber of Commerce, Friday, called for the purpose of combating prostitution in Macon. Those who took part in the meeting were of one mind as to driving out street walkers and cleaning up malodorous hotels. The colonel addressed the Red Cross chapter the same evening.

Shortage of overcoats, blankets and heavy uniforms is believed to have been a factor in the recent increase in sickness.

The commissioned medical personnel of the Third Division is almost complete. Half a dozen medical men are now here, caught by the draft net. They will be examined for commissions.

BASE HOSPITAL NOTES

With seven wards of the 500 bed hospital incomplete and unoccupied, 642 patients are being well cared for tonight, just nine days from the opening.

As is to be expected in a new camp, measles and venereal diseases comprise a large majority of the cases, there being 271 of the former and 135 of the latter.

There is one case each of diphtheria, cerebrospinal meningitis and varioloid, and twenty cases of pneumonia.

The admissions are already well over the 900 mark.

The commanding officers' quarters were burned on the night of the 24th, and it required strenuous efforts on the part of the corps to save the hospital; but not a patient was injured or even disturbed. Before the ashes were cold, rebuilding began.

The enlisted men have met the situation as soldiers should, and have done the work, though there are no nurses to help and the corps itself consists of only 126 men, being about seventy short. This shortage was supplied today by drafting on the field hospital for men; the Nurse Corps is expected soon.

The base hospital subscription to the Liberty Loan was the highest per capita of any organization in the division, and entitled to first place in review; but officers and men were too busy to attend.

ONE HUNDRED AND SIXTH SANITARY TRAIN

At the Division Review, with the organizations rated according to their per capita subscriptions to the Liberty Loan, the sanitary train occupied the position of honor on the extreme right of the division. With a commissioned personnel of thirty-four and enlisted strength of 378, the total per capita subscription per man was $65.16. The total amount subscribed by officers was $5,750, a per capita credit of $168.82; the enlisted subscription was $21,100, or a per capita of $55.82. The ambulance company battalion led the train, having a few more dollars per capita to its credit than the field hospitals. The leading company of the entire train was Ambulance Company No. 121, commanded by Capt. Robert F. Ashworth, Medical Corps, Alabama National Guard. The passage in review was well conducted, alinements were accurately maintained, and favorable commendation was heard on the appearance of the medical troops in comparison with their brethren of the line.

The camp site formerly occupied by the camp hospital has been cleared and burned over. The removal of the many hospital ward tents of the field hospital companies has left a void to which, as yet, our eyes are not accommodated. Despite the size of the task we had, we frankly admit that we miss it.

On the night of the fire at the base hospital, the Florida, Georgia and Alabama field hospitals held themselves in readiness to pitch their canvas to accommodate the 400-odd patients of the base hospital, should the spread of the conflagration require it. The ambulance companies stood ready with their entire motor and mule-drawn equipage to evacuate the wards should it become necessary. Fortunately the flames were confined to the small building in which they started, and we were enabled to turn in with our minds at ease.

The work on the framing and flooring of the tents of this command is now practically completed, with the resulting increase of comfort of the men during the chilly nights.

The tremenduous amount of work being thrown on the base hospital, with its inadequate enlisted personnel, has necessitated the detailing of a total of seventy-two men from the train, thirty-six from the field hospitals, and thirty-six from the ambulance companies. While this interferes, to some extent, with the maintaining of a uniform drill schedule, it is evident that the knowledge acquired by these men at the base hospital will be invaluable and tend more rapidly to complete their training as members of the medical department.

On Wednesday evening, last, the weekly social of the officers was held with its usual success. The brisk air of the evening added to the enjoyment of the dancing. Luncheon, with coffee, was served in the mess hall between dances. The orchestra of the Florida field hospital augmented by a new violinist rendered the music.

The anticipation of a roast possum dinner was destroyed by the fact that some unkind person liberated Brother Possum from his cage. Said possum was captured in a foot race by Major Job C. Patterson, director of field hospitals. The genial major must secure another animal in order to make good his repeated promise of "possum and 'taters."

The organization of ladies' committees for the procuring of delicacies for sick soldiers is progressing favorably, the idea being to concentrate especially on those men who are convalescing from serious illness.

The missing flat car has finally arrived, containing the two motor ambulances necessary to complete the full complement of one company now on hand. This now gives us twelve standard GMC ambulances and No. 13 Car, known as Spare Parts and Repair Car. The good news that another complete motor ambulance equipment is on the way has been received. The motorcycle cars, with their "bath tubs," we understand, are also en route.

Fortieth Division, Camp Kearney, Linda Vista, Calif.

The cantonment of the Fortieth Division is located on a plateau, 17 miles northeast of San Diego. The surrounding country is sparsely settled and furnishes enough variety of contour to allow maneuvers of all kinds to be made. It is covered with a scrub brush of greasewood, sage brush and cactus. The soil is shallow, of the type known as gumbo. A few inches below the surface is a strata of hard pan impervious to drainage. All excavations in the cantonment had to be blasted. The amount of the annual rainfall in this vicinity is very limited and confined to the winter months. There are no streams or springs in the vicinity of the camp and very few wells. The water supply of the cantonment is furnished by the city of San Diego, which installed a complete pipe line, with reservoir, to take care of the cantonment. A complete sewer system was installed, with septic tanks. The garbage is removed by contract. Refuse is hauled to a designated dumping ground some distance from the camp. The climate is equable, the temperature never reaching the freezing point. Variation from noon to midnight is great, but no provisions have been made for heating the tents. The ocean is only a few miles from the camp so that fogs are often found in the early morning. The number of cloudy days is practically nil.

PERSONAL

There are several medical officers attached to the Fortieth Division who have seen active service abroad. Major W. A. Jolley served with the American Red Cross at Belgrade, Serbia, during the typhus epidemic and was present during a bombardment and capture of Belgrade by the Germans. Major J. R. McDill was sent to Germany for the American Physicians Expeditions Committee of New York in June of 1916. Major Phillip S. Chancellor was in France for several months in 1916. Lieut. Kenneth Beymer Turner was an officer in the English Expeditionary Force in Serbia. He was given a commission in the French Army after the invasion of Serbia. On the entrance of the United States into the war he returned to America and joined the army of the United States. Capt. Byron Stookey served in France with the Harvard Surgical Unit during 1915. These officers will be a great value in preparing the division for foreign service.

Forty-First Division, Camp Greene, Charlotte, N. C.

This camp is made up of militia organizations of the several Western States, to wit, Washington, Oregon, Idaho, Montana, Wyoming, New Mexico, North Dakota and South Dakota. It makes a distinctive unit, as a war factor, because many of the men served on the Mexican border. Of course there have been quite a few new enlistments since then, but a good nucleus for a fighting machine had already been started. The change from the West to the East has added "pep" to the men. All want to show what good material the West can produce to help win victory for our country.

The camp is pleasantly situated in a rolling country and mostly in cotton fields. The climate is good, and the surroundings aid to make a good training camp. All officers and men are housed in tents, with floors and sides. For heat, the Sibley stoves are used, thus making it comfortable for all.

The base hospital has an area of about 67 acres, and has buildings erected for all conveniences of patients and attendants. Major W. L. Sheep, M. C., U. S. Army, is the commanding officer, and there are thirty-one medical officers and 125 enlisted men. All those with contagious diseases, all who require medical or surgical treatment, other than those slightly ill or wounded, and those under observation are sent there. At the base hospital a staff for dental work is established, besides the regimental units, which have one or more dentists assigned to duty with those units.

Capt. John T. Rugh, M. R. C., has been assigned as instructor in orthopedic work. Lieut. Paul V. Anderson, M. R. C., is in charge of the neurologic department. Major Francis W. Palfrey, M. R. C., has charge of the tuberculosis and heart examinations. These medical officers examine the men of the division in their separate specialties, and weed out the noneffectives, all of which aids in the building of a very effective fighting machine.

Capt. Leonard A. Ensminger, M. R. C., is the medical officer assigned to give instructions to all the officers and men of the division in gas defense.

Lieut.-Col. O. G. Brown, M. C., U. S. Army, is the division surgeon. The assignment of all the medical units is made through his office, which entails an immense amount of good judgment and experience.

The sanitary train is composed of four field hospitals and four ambulance companies. Its quota is practically completed.

The percentage of sickness in the camp has been the lowest, with one exception, of all the cantonments. One death has been reported thus far from pneumonia. Meningitis has appeared in the camp; two cases were positive, one reported not positive. All the patients are recovering. Strict quarantine and other measures are taken to prevent the spread of the disease, including microscopic examinations of cultures taken from the posterior nares of all men in quarantine.

SOCIAL AND PERSONAL

Brig.-Gen. Henry Jervey and wife entertained, Saturday, October 13, from 2 until 6 p. m., for officers of the division.

Regimental bands play daily at the commanding general's headquarters from 4 to 5 p. m.

The study of French has been taken up by officers and men, and classes are held at regular intervals.

Eightieth Division, Camp Lee, Petersburgh, Va.

When the last notes of Camp Lee were sent to The Journal there were 38 medical officers assigned to the base hospital and 80 medical officers in the division. Since that time 59 medical officers have reported.

With the steady increase in the number of troops at Camp Lee the increase in the medical commissioned personnel was warmly appreciated and it will considerably lighten the labors of the medical officers. There are a number of training battalions at Camp Lee as well as the regular units of the division. The medical officers attached to these battalions have been constantly busy with physical examinations and mustering and then when they see the end of this work they suddenly learn that these new troops are to be transferred to some other camp. A surgeon accompanies each group of men that are transferred, and when the medical officer returns he finds physical examinations and muster awaiting him again. Captain Williamson, Lieutenants Tunnell, Stover and Miller have recently been through this experience and Lieutenant Miller's report of his work since his arrival shows what the medical work of these battalions means. Lieutenant Miller arrived in the middle of September and began the work of completing the physical examinations. Just as he was nearing the end of his work he was assigned to assist another medical officer's unit in their mustering work. This work completed, he accompanied 600 men to Camp ——. Entrained at Camp Lee, Friday morning, Capt. Alfred Degerman in charge, and reached Camp ——. Though the skies were overcast, not so the spirits of the men, who were joyous as they marched to the training station led by the junior line officers who had labored with them for several weeks to get them in shape for movement. So diligent was this work that, amazing as it may appear, these men, mostly from the farm, workshop and mine, were transformed in this quite short period to acceptable looking and acting soldiers. Their behavior en route was excellent and the medical officers had but two unimportant cases to attend. In contrast to other troop trains reaching Camp —— at or about the same date, this command was unfortunate in that there were no sleeping accommodations provided for officers or men. In addition, through failure to provide a key for the gas supply, the train was in darkness until between 8 and 9 p. m.; a station was reached where a key was procured, but in spite of these discomforts and the unfortunate inability of the supply officer to procure coffee for the men Saturday morning, they still had "kick" and were full of "pep" as they marched to the receiving station on leaving the train. Here we were met by the receiving officer and our commanding officer, relieved of further responsibility, every man responding to his name at roll call. Camp —— is beautifully situated, just 13 miles from —— with a fine approach of improved road. While we were favorably impressed with the camp, we all voted Camp Lee, Va., "Premier," and were not loth to return, arriving at Camp Lee, Va., on Tuesday.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

SOCIAL WORK FOR SOLDIERS

Since the number of men on the streets of Louisville has been increased by the soldiers in the cantonment at Louisville, the civic bodies have again begun the agitation in favor of the establishment of public comfort stations in the downtown district. The importance of these stations was emphasized by the Louisville Commercial Club, during the presidency of Dr. Henry E. Tuley, but succeeding city administrations have plead limited finances as an excuse for not erecting one or more stations. It is now pointed out that the daily population of Louisville is about one fifth more than at the beginning of the war, caused by the presence of the soldiers and the visitors brought to Louisville. The opening of the new Soldiers' Club House, at 619 Fourth Street, a four-story building, with all conveniences, will greatly aid but not meet the demands for such stations.

A special detail of officers clad in private's uniforms set out on Saturday for the purpose of securing information as to whether soldiers are securing intoxicating liquors, and in a general way investigating all form of vice. Col. C. F. Crain, provost-marshal, is endeavoring to limit both bootlegging and pandering in the outskirts of the camp reservation and in the city.

The Sick Soldiers' Cheer-Up Club is a new organization composed of the wives and daughters of out-of-town officers stationed at Camp Zachary Taylor. The club made its first visit to the camp base hospital and brightened the day for many a sick and convalescent soldier with gifts of flowers, fruit, cakes, cigarets and matches.

THE BASE HOSPITAL

At present, there are about fifteen wards occupied, three isolation, four medical wards, four genito-urinary, two surgical, one eye, and one nose and throat. There are about 400 patients in the hospital. Of these there were fifty-five measles, nineteen mumps, twenty-eight pneumonias and one cerebrospinal meningitis. There have been two deaths from pneumonia and one from streptococcic cerebrospinal meningitis. The medical staff is preparing to use the pneumococcus serum Nos. 1, 2, 3, 4 as soon as it can be sent from Washington, D. C. They are also examining for meningitis carriers and are planning to use in them the prophylactic treatment with meningococcic vaccine.

EXAMINATION OF DRAFTED MEN

Capt. Philip Stewart, Paducah, in charge of the surgical service at the base hospital, examines for the general surgical conditions such as hernia, flat-foot, joint injuries and for alleged or supposed defects which make the recruit limp in drilling. There are many of these, and it requires great skill and clinical judgment to detect those suspected of malingering. Capt. Victor Meddis, Louisville, has charge of the venereal cases. A great many cases of active syphilis are rejected. A great many recruits enter the camp with acute gonorrhea. These are isolated and treated for a few days, and if no complications exist, are then assigned to duty. Tertiary syphilis patients are not discharged but treated under Wassermann control. The neurologic cases are under the charge of Major Milton Board of Louisville. The neurologic ward is well equipped with special rooms for the observation of special cases such as dementia praecox, epilepsy and the acute insanities. Major William H. Wilder, Chicago, acts as consultant to the ophthalmic division of the reviewing board, while during his absence the work is in charge of Captain Barton. A great many cases of trachoma have been found. These are promptly rejected. At one time there were forty-five cases in an isolation ward under observation. Major Frederick Menge, Chicago, is in charge as consultant of the ear, nose and throat division. During his absence this department is looked after by Capt. Lawrence Littig, Davenport, Iowa. Capt. M. J. Lichty, Cleveland, examines all suspected cases of tuberculosis. A board of tuberculosis examiners, consisting of ten officers of the reserve corps, contract surgeons, will shortly begin an examination of every accepted man in the camp, including all officers. The cardiovascular examinations have been made by Dr. Willard J. Stone, Toledo, contract surgeon. About 50 per cent. of all recruits referred for alleged disease of the heart are rejected. The remaining 50 per cent. are found fit after tests designed to show the fitness of the recruit to stand effort. A large number of hearts showing functional murmurs are accepted, while many supposed functional or accidental murmurs are found to have definite evidence of earlier infective damage to the valves or myocardium. In questionable cases the heart is examined by the fluoroscope and roentgen-ray plates are made by Captain Sprague, in charge of the roentgen-ray laboratory.

The action taken by the reviewing board as to physical fitness for service is final when approved by the division surgeon, Colonel Allen, to whom all papers are referred for final action. A great many letters are received from anxious parents, public officials and interested friends of him concerning the disability of certain recruits. Considering the manner in which the recruits were examined by local boards for the selective draft it is surprising that more gross errors of judgment are not found. About 3,000 cases have been referred to the reviewing board for decision, out of approximately 27,000 men in the camp. Of this number referred approximately 50 per cent. have been found to be unfit for service. The reviewing board has had some interesting cases of malingering follow certain rejections for genuine disabilities. Cases of malingering have followed rejections for pulmonary hemorrhages, nocturnal enuresis, chronic rheumatism, defective vision, and peculiar gaits.

PERSONALS

Major John Ridlon spent several days at Camp Zachary Taylor recently, during which time he gave two lectures to the medical and line officers on the care of the feet. Dr. Ridlon spent one summer at Plattsburg with the Medical Officers Reserve Corps in training there.——The officers of the reviewing board are: chairman, Major Walter Hamburger, Chicago; recorder, Lieut. Willard J. Stone, Toledo. Major Hamburger is also president of the disability board, chief of the Medical Service and member of the auditing and hospital council. The disability board has to do with the examination and discharge of enlisted men. Many new recommendations are being made by the Surgeon-General's Office to meet new war conditions.——Under Major Worthington, M. C., U. S. Army, commanding officer of the base hospital, all medical men attached to the hospital are drilling one hour a day, four days a week, and four night classes are being held a week on "Army Regulations" and the "Manual of the Medical Department of the Army."——Major-General Hale has extended the hours of leave for the drafted men to Wednesday and Saturday afternoons and Sundays. Medical officers have leave also on these days.——A wonderful service is being rendered the base hospital staff by a local organization known as the Woman's Service League in supplying needed equipment for the hospital. Ice bags, refrigerators, instruments of all descriptions, and special nurses in certain cases have been supplied on request of the commanding officer.——Steam was turned on in the officers' barracks at the base hospital for the first time on October 27. This was a welcome addition to the comfort of these hard-worked men. Pending the heating of the wards all seriously sick soldiers were sent to the soldiers' ward at the City Hospital. At the request of Major Worthington, the City Hospital Committee representing the University of Louisville recommended the appointment of Major Hamburger and Lieutenant Flexner, as members of the medical visiting staff, and Captains Stewart and Price, of the surgical staff, and Captain Sprague, visiting roentgenologist. One death has occurred at the City Hospital of a soldier from acute mania.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Oct. 19, 1917

1. Total strength of troops 988,372
   Admission rate per 1,000 (disease only) ....annual 974
   Non-effective rate (all causes) 21.6
2. National Guard—strength 314,174
   Admission rate per 1,000 all camps (disease only) ..annual 952.6
   Non-effective rate all camps (all causes) 23.5

The following camps show admission rates for disease higher than average: Camp McClellan, 1,077.4; Camp Wheeler, 1,043; Camp Logan, 959.3; Camp Cody, 1,146.5; Camp Doniphan, 1,504.6; Camp Bowie, 1,001; Camp Shelby, 1,253.4; Camp Beauregard, 1,689.9; Camp Kearney, 1,279.5; Camp A. L. Mills, 1,221.7.

The following camps show non-effective rates (all causes) higher than average: Camp MacArthur, 36.6; Camp Logan, 29.05; Camp Doniphan, 27; Camp Bowie, 27; Camp Shelby, 38.1; Camp Beauregard, 33.9; Camp A. L. Mills, 31.4.

3. National Army—strength 421,619
   Admission rate per 1,000 all camps (disease only) ..annual 1,014
   Non-effective rate all camps (all causes) 17

The following camps show admission rates for disease higher than average: Camp Dix, 1,091.4; Camp Lee, 1,148.7; Camp Gordon, 1,079; Camp Pike, 1,220.3; Camp Dodge, 1,098.7; Camp Travis, 3,493.7.

The following camps show non-effective rates (all causes) higher than average: Camp Dix, 17.5; Camp Dodge, 24; Camp Travis, 40.6; Camp Lewis, 25.1.

4. Venereal Disease—
Admission rate Regulars 77.8
Admission rate National Guard (Camps) ....annual 118.8
Admission rate National Army 146.4

The following camps, National Guard, have rates above average: Camp Sevier, 254.7; Camp Wheeler, 168.2; Camp Logan, 158.5; Camp Cody, 148.5; Camp Bowie, 153.3; Camp Sheridan, 146.9; Camp Shelby, 142.3; Camp A. L. Mills, 186.8.

The following camps, National Army, have rates above average: Camp Jackson, 367.9; Camp Pike, 629.8; Camp Funston, 174.6; Camp Travis, 486.4.

5. Number of cases of pneumonia 198
Highest number in any one camp ....(Travis) 41
Number of cases of meningitis 12
Highest number in any one camp ....(Funston) 4

6. SPECIAL DISEASES REPORTED DURING THE WEEK ENDING OCTOBER 19, 1917

THE CONTROL OF VENEREAL DISEASE IN THE ARMY

The meeting of the College of Physicians of Philadelphia, Oct. 3, 1917, was devoted wholly to a discussion of the control of venereal disease in military life. Major George E. de Schweinitz, M. R. C., presided. Before the meeting Dr. W. W. Keen presented to the college the retractor used in the operations on President Cleveland in 1893.

The Problem of Dealing with Venereal Diseases in Great Britain

Col. T. H. Goodwin of the British Army was warmly greeted. "Estimates made by the Royal Commission on Venereal Diseases," he said, "indicate that *in the* larger towns in England at least 10 per cent. of the total number of inhabitants is *infected* with *syphilis*, and that *gonorrhea* is even more prevalent. This would mean that in London alone there are 450,000 *syphilitics. Sir William Osler places this* disease as third on the list of what he terms 'killing diseases.' That venereal diseases have *not been* adequately *grappled* with as have other infectious diseases is due to the mistaken *policy of silence." In the Army, notwithstanding that the* best methods of treatment are in vogue and that the incidence *of the disease has been diminishing, it was found that in* 1912 the average number of men incapacitated was 593 which, with an army of *107,000* men, represented a *loss of over* 216,000 working days in the year. The rate of the incidence of the disease in the Army in 1913 was 5.3 per cent. per annum; for 1916 it was 2.1 per cent. per annum. During active service the disease is more adequately dealt with than during peace. Improved methods of educating the soldier on this matter, the provision of greater facilities for recreations in cantonments, and the decrease of alcoholism have had a very considerable effect in decreasing the incidence *of* venereal diseases. The national council for combating venereal disease, with Lord Sydenham as president, embraces many leaders of the medical profession, representatives of the churches, and many women social and philanthropic workers in close coöperation. The aims of the council are briefly: (*a*) provision for education and enlightenment; (*b*) provision of greater facilities for treatment; (*c*) provision of increased opportunities for study of these diseases on the part of medical practitioners and students, and (*d*) promotion of legislative, social and administrative reforms.

Up to June of last year, more than 600,000 soldiers had attended the lectures *given. The point of* view taken by the royal commission is that it is both the duty and to the interest of the state to see that venereal disease is promptly cured. Facilities for diagnosis are organized so far as possible in connection with existing laboratories in universities and in general and county hospitals. Wards in general hospitals for indoor patients are allocated to venereal patients. For outdoor patients, evening clinics are provided. The objection to the provision of special hospitals lies in the resulting publicity. It is recommended that salvarsan should be provided gratuitously, under proper safeguards, *to private practitioners* for use among the poorer patients. Sir Malcolm Morris believes that under present conditions *compulsory* notification and treatment are impracticable. Sir William Osler would welcome notification. The conclusion *of* the *royal* commission was against this measure. "I myself am strongly in favor of the adoption of compulsory *notification*," said Colonel Goodwin, "and believe that with the advance of education and the recognition of the gravity *of the* matter, this will be enacted. The commission emphatically recommends the prohibition of all advertisements *of remedies* for venereal *diseases*, and favors the legal prohibition of treatment by unqualified persons. Some difficulty *obtains*, however, in securing such a law at present. I believe," he continued, "that unauthorized treatment of these diseases *should* constitute a *penal* offense. I also think that it should be the duty of a medical man to acquaint the parents *of any* girl who contemplates marriage with a man whom he is treating for venereal disease, and that such *communication* should be recognized as *privileged*. The wilful communication of venereal disease should, in my opinion, constitute a legal crime. While the proof *of* knowledge might be difficult, the measure would tend to the good of the community. This present world-wide war, apparently productive of nothing but evil, is teaching us to regard life and death *as less* important than the future welfare of mankind; and if such matters as adequate control of venereal diseases, world-wide prohibition of alcohol, and an increasing, instead of a decreasing, *birth* rate result, it may possibly be found that, terrible as it is, it was not without some good results."

The Preventive Tide of Social Disease

The next speaker, Mr. George W. Braden, of the Central Y. M. C. A. of Philadelphia, stated that the moral standards maintained in a military camp greatly affect the venereal disease ratio. A study of the Mexican border situation made by Mr. Max Exner of the Y. M. C. A. International Committee and a member of the Fosdick Commission on Training Camp Activities states that when men were kept busy with wholesome games and amusements, proper educational service was rendered and temptation removed as far as possible in nearby towns, the number of men applying for prophylactic treatment was very low. Mr. Braden cited figures from several of the camps under varying conditions which showed definitely that the incidence of application for prophylactic treatment was far less when proper recreation was provided.

Social Diseases in the Army as Affected by the Soldiers' Environment

Major William F. Snow, M. R. C., emphasized the practical details which the Army is carrying out in the prevention of venereal diseases. "As a medical profession we have not quite become convinced," he said, "that the venereal diseases are amenable to the same methods of attack that we have applied to the other communicable diseases. We are, however, on the eve of carrying this application into effect. In venereal disease we have a problem of the human carrier, and therein lies our difficulty because the carriers spread the disease through the development of habits opposed to the moral standards of the community. The circumstances connected with the control of these individuals is such that we either have to legalize their immorality or interfere with the liberty of large numbers of persons. Controlled prostitution has been found inadequate in the epidemiology of venereal diseases, to say nothing of the opposition of the public to this method. It has taken this war with the ten or fifteen years of effort and education to bring about a crystallization of public opinion to try other methods of controlling venereal diseases." Education and recreation, he believes, are the chief steps. The control of alcohol has been put forward by almost all persons interested in this problem as one of the biggest factors in the control of prostitution and therefore in the control of these diseases. The government combines these agencies in two major groups, the group dealing with education, recreation and entertainment, and the group dealing with police power with control of alcohol and the repression of prostitution. Congress has given the President and the Secretary of war authority over zones around all our military camps. The secretary of war has created the Commission on Training Camp Activities, which is developing a network over this country of voluntary cooperation to do whatever can be done along these lines of effort. So far as the Army is concerned, the various commanders are finding groups in the communities who are interested in the stimulation of this effort. There will be some soldiers, however, who will expose themselves, and stations are being established for treatment, and the Army is making a special effort to render the treatment station an educational matter. Some will fail to receive treatment in time, and will develop the disease. The genito-urinary men attached to the Surgeon-General's staff will make every effort to obtain the social facts from the soldiers to make it possible to trace the carriers. In Canada there has been much encouragement felt by the cooperation of the soldiers in tracing the carriers in civil life. In order to combine all these efforts, the Surgeon-General has created under Colonel Russell a department that will devote its efforts primarily to this preventive phase of the venereal diseases. Inside the camp, certain officials will be working with the regimental surgeons in studying the cases that develop. Sergeants who are especially trained will work with the officials in ascertaining the facts without embarrassing the soldiers or making the matter appear to be a disciplinary measure. In order that such information may be used wisely, a series of officials are being appointed who will work in the extracantonment areas whose chief business will be to know the attitude of the community toward the problem, to know the health official and the other forces that may be counted on to carry through any effort to find carriers in the civil community.

Social Diseases in the Army

Col. Frederick F. Russell, M. C., U. S. Army, chief of the division devoted to laboratory work, said that syphilis and gonorrhea can now be placed with other infectious diseases and not classed merely as moral and social problems. The Army surgeon in the United States has absolute control of the soldier inside the reservation. In time the new citizen soldier will learn that he is a part of the great world machine, and his ideal will be to keep himself in the pink of condition. We have a large number among our recruits who immediately become patients. In the old days most army posts were surrounded with evil places over which the Army had no control. At present the law gives us control of a zone surrounding each camp where the commanding officer has almost complete police power. We shall have to contend with more venereal disease in the Regular Army this winter than ever before. The third week of the draft Army showed an astonishing increase in the number of cases of venereal disease. Whether this means that these diseases are much more common among young men of military age in the civil population than we ever supposed, I do not know. Certain it is, however, that we have almost 400 per thousand, whereas our highest rate in the last twenty years in the Army has been 162. Treatment begins from the first day the men begin to assemble, and we now have hospitals full of draft men with venereal disease which they contracted before joining. The most interesting point is not of recovery but of how many days it will be before the patient is returned to his military duty. In their order, the commonest diseases in the service are venereal diseases, tonsillitis, influenza, bronchitis, diarrhea and enteritis. The Surgeon-General has had prepared a small manual on the present day methods of diagnosis and treatment of venereal diseases. We hope by means of this manual and the service of qualified specialists as consultants to standardize and develop this field of medicine, and bring home to every physician the great value of modern scientific treatment. We shall institute early treatment of venereal infection by all the so-called prophylactic methods, if possible within a few hours of exposure. We shall make frequent inspection of the troops to discover concealed cases. We shall penalize a man who develops venereal disease by taking away his pay and his liberty until he is cured. If he develops venereal disease and does not avail himself of the facilities of treatment, he will in addition be courtmartialed, and if found guilty he will be placed in confinement at hard labor. If in spite of these requirements he develops disease, he will be sent to the hospital, put to bed, and be given a course of intensive treatment until he is no longer a source of contagion to others and is well on the road to recovery. Without the cooperation of the civil practitioner, the help of the social worker and of the public as represented by the civil and state authorities, the Army surgeon will not be able to accomplish more than has been done in the past. Success depends on the earnest support of the entire medical profession of the country.

General Discussion

Dr. Edward Martin described plans for the cooperation of the civil medical profession of Pennsylvania. "We mean to have our health officials treat the man with gonorrhea and syphilis, or both, who cannot be kept under medical control, with as little respect as to his rights as they would treat one suffering from smallpox. Our state committee will recommend to the legislature that places be provided for the treatment of such patients. There is no reason why hospitals receiving state aid should not take these patients within their doors and keep them until they are no longer sources of danger, except in institutions in which girl babies are cared for. Here gonorrhea should be excluded. In every county of each state there is a subcommittee of the Council of National Defense, and before the war is over we hope to have a law by which these diseases under national restriction must be reported, and by which a person conveying them knowingly or otherwise may be liable for criminal prosecution or damages.

Major E. H. Siter stated that when the war is over and the men in the Army have seen the efficient treatment there instituted and have known the ravages made in the ranks, the great etiologic factor will, he believed, be corrected. It is not the professional prostitute who does the damage, but the casual prostitute hanging about the cantonment. The disease must be treated intensively. This cannot be done except in a hospital.

Dr. Jay F. Schamberg mentioned the recent organization at Cincinnati of the American Society for the Control of Syphilis. The membership is composed of specialists who will develop the activities along medical, legislative and educational lines, cooperating so far as possible with the American Society of Social Hygiene. "Until recently, a dose of salvarsan has cost $4.50 an ampule, which prohibits its adequate use with all the indigent sick. It has been impossible for those making salvarsan or its equivalent in this country to supply the drug directly to the profession because of the patent laws. The Adamson bill, however, which has just passed House and Senate, authorizes the President to license American citizens to prepare and market products patented by alien enemies, and provides for the payment of 5 per cent. of the gross receipts to be deposited in the United States Treasury until the end of the war. The Dermatological Laboratories have made application for license to distribute arsenobenzol. Over 125,000 doses of this drug have been used already in the United States. It is our purpose progressively to lower its price, that it may be freely available for the indigent sick. We propose as soon as licensed to place arsenobenzol on the market at $1.50 to physicians, and to hospitals in larger sized ampules at such a price that an individual dose may be administered for about 80 cents. The adequate use of salvarsan on the ambulatory dispensary patients is of vital importance in the stamping out of contagious syphilis."

Dr. H. M. Christian believed that we must protect the man in the Army from the result of his own immorality, for the benefit of the service and his associates. "That which is of vital importance is prophylaxis; and I regret," he said, "that more emphasis was not placed on the prophylactic treatment of men on their return to camp. Statistics tell us that when prophylaxis is carried out as a routine, the percentage of development of venereal disease has been very small. Prophylaxis is not a compromise with evil, as so many regard it. We as physicians have no discussion here of morals; we are interested in the safeguarding—at this of all times—of the health of our Army. It is all very well to give these men instruction and entertainment, but far better to my mind to safeguard them by enforced prophylaxis."

Colonel Goodwin said in closing that he did not think the soldier is more immoral than men of the same class in civil life. We can do an enormous amount to keep him away from the opportunity of getting venereal disease, and the measure which has helped more than anything else in the Army to carry this out is the increased facilities for amusement. In this connection the Y. M. C. A., he believes, is of utmost importance.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA

"War Session"

SECOND EVENING

The second evening session was held in the Gold Room of the Congress Hotel, Tuesday, October 23. The meeting was called to order by the president, Dr. John T. Clark.

Symposium: Sanitation and Sepsis

THE WORK OF THE ARMY SURGEON

Surgeon-General Gorgas introduced the general subject of the work of the military surgeon. He said his personal experience in military surgery was nil; he had been in service for forty years, but during that time we had been involved only in the Spanish-American War, and since that time military surgery had been practically born over. This war has demonstrated the fact that we shall have to add enormously to the procedures that will have to be adopted before victory comes. The whole situation revolves on the question of sepsis. The endeavor of the military surgeon should be to get at the wound as quickly as possible and render it free from infection as soon as he is able. The principal rôle of the administrator will be to get the men at the earliest practicable time, and with this object in view we should have our hospitals as near the front line as possible. All our plans will be bent toward this end.

THE WORK OF THE NAVY SURGEON

Surgeon-General Braisted said it was impossible in the time allotted him to give a compresensive idea of what had been done, or of the problems and the enormity of the task before us. He called attention to the enormous increase in the number of enlisted men in all departments of the Navy, and to the fact that the medical department must also look out for all the men engaged in the construction work for the Navy, which made the total between a fourth and a half million people for whom the Navy was responsible. There were formerly 394 medical men in the Navy; there are now 828 in the regular service, this being the full authorized strength of the corps. They were obtained through a campaign which was instituted in the Class A men of the large medical schools of the country, and are a credit to every one. The Navy has twelve hospital units organized under and in conjunction with the Red Cross, and five small naval stations, the majority of which are rendering service. Four excellent hospital training schools are maintained by the Navy, and there are sometimes 100 men in training. Two ships are being transformed into hospital ships, and one is being built from the keel up as a hospital ship that is of a type never before contemplated in the history of the world. The Navy is well equipped in every way and able to meet every demand that may be made.

IN THE TRAINING CAMPS

Col. E. L. Munson, M. C., U. S. Army, in charge of the medical officers' training camps, told of these splendid camps that have been established for medical officers. There were approximately 500 medical men at the outbreak of the war who were capable of playing the medical war game as it should be played. The law authorized seven medical men per thousand, but experience abroad has shown that ten per thousand is better. The corps has been increased until now the doctors and dental surgeons alone outnumber the whole Army of the United States when it went to war with Spain. The Surgeon-General was confronted with the problem of training these men, and at once secured authority to establish training camps for this purpose. There are now three of these camps, besides one for negro officers and one for the Ambulance Corps. The training is at first physical, for the average doctor who comes in is in need of vigorous training to fit him for the tasks ahead. He is trained as a soldier until he can go as far as the rest in every way, and stand a full days' work beside. He must be taught how to do everything necessary, for he will have to tell others how to do it when actually in service.

Col. Munson's talk was illustrated by lantern slides and moving pictures showing the life in the camps.

MILITARY LABORATORIES

Col. F. F. Russell, M. C., U. S. Army, director of laboratory activities, spoke of the necessity of having well equipped laboratories that could be operated on the same principles that are now carried out only in the larger cities. New laboratories are now to be established at all cantonments and in general hospitals at the posts throughout the country. Those at the cantonments must be able to carry on the work of a community of from 20,000 to 50,000 people. The difficulty in securing supplies and apparatus is now being met; the principal articles have been delivered at all cantonments; and additional supplies will be furnished as rapidly as possible. A great many women laboratory workers have offered their services, and will be used as civil service employees as the need arises. Two classes of work will be done: clinical pathology for diagnosis in connection with the camp hospitals, and the routine examination for typhoid carriers, hookworm carriers and infectious diseases. The laboratories will also prepare all the vaccines and serums necessary for all the work done in the cantonments, and hope to do all the work that is now being done in the best institutions in a city. Much work has already been done in the new diseases of the war—trench fever, trench jaundice and gas gangrene. Many research institutions have offered their services, and all who have worked under General Gorgas have complete confidence in the future of the Medical Corps under his charge.

Gunshot Wounds and Their Treatment

Sir Berkeley Moynihan, Leeds, England, was sure that surgeons who were called on at the outbreak of this war to treat gunshot wounds in men coming over from France were never likely to forget their experience. They had occasionally encountered cases of suppuration, but never in the experience of medical men in our generation had cases of virulent infection like these been seen. The surgeons were scoffed at and told that they had never learned the lessons that Lister has spent his life in teaching, or, having learned them, had made haste to forget them. On reviewing Lister's books he found that he clearly distinguished in every one of his writings between the prophylactic work of antiseptics and their therapeutic values. The original idea of the antiseptic system was the exclusion of all microbes from the wounds, and the more or less successful attempt to restore wounds already septic to the aseptic state, so it was no just tribute that was brought against the surgeon when he was told that Lister had lived in vain and that aseptic surgery had fallen grievously to the ground.

Sir Berkeley described the way in which a German rifle bullet travels, and the different types of wounds made by it. The soldiers claim that the enemy uses an explosive bullet; and he said that while he knew the kaiser could use every iniquity that could possibly pay, and every kind of infamy if it pays at the moment to do it, he does not use the explosive bullet because it lacks the accuracy of aim that is present in the one he does use. One effect of the utmost importance produced by this bullet as it charges its way heavily and clumsily through the tissues, with the terrific momentum of 1,000 meters per second, is that it not only tears apart the tissues but also kills them by means of its terrific velocity. It also drives into the tissues everything with which it comes in contact; and if a bone is encountered, every tiny fragment becomes a projectile in itself and is driven into the tissues all around. These bullets have been shown to penetrate not only the body of one man but also the bodies of two, or even three, in succession. It is interesting to know that you may take the parts of one man out of the wound of another man through whom the bullet has passed. A part of a pocketbook of one man may be driven into the side of another, and the golden sovereigns in the hip pocket of one man may be removed from the buttock of the man who stood behind him. During the last two years, wounds produced by high explosives and shrapnel have increased in number. A gunshot wound depends for its qualities not only on the missile which is used but also on the man whom it meets. "It is impossible to exaggerate the intimacy of the contact between the soldier and the soil on which he is fighting." Flanders is probably the most highly cultivated region in all of France, the soil having been fertilized and refertilized for many years, with the result that the mud is of a particular bacterial malignancy. All the kinds of infection that occur in gunshot wounds are those which come from the fecal bacteria found in this soil, the streptococcus and bacillus of Welch being the most frequent. The men receiving these gunshot wounds are weary almost beyond endurance, are suffering shock, and all the circumstances both local and constitutional are in favor of a rapidly spreading infection. From a surgical point of view it is evident that there should be brought together at the earliest possible moment after the infliction of the wound the wounded man and the best surgical help that is available. This means that we want the best surgeons who are young at the most advanced point in the service to which it is safe to send them, and where they can have all the material surroundings which make for safety in surgery. The one thought should be to obtain complete closure of the wound at the earliest possible moment, either by primary or by secondary closure. Primary closure consists in excising the wound as completely as possible and in one piece, in order to avoid the reinfection of the new wound that the operator is making. This is capable of being carried out in a very large proportion of cases if the surgeons have the courage to do it, probably in 80 or 90 per cent. of the suitable cases. The principles and ideals for which to strive in badly infected wounds are to bring in larger quantities and on a rising tide the swarm of leukocytes into the wound, and perhaps to increase their activity by vaccine therapy, or to make use of the increased antitryptic power of the blood in very grave infection; and there must be complete immobilization, to prevent movements which carry poisonous bacteria into the blood.

Regarding antiseptics, Sir Berkeley said that from a military point of view the Carrel-Dakin method was an extremely difficult one to practice. Many people think a large part of the success of this method is due to the fact that the patients are received early, are placed at once under this careful, rigid technic, and are retained for long periods. The great fault of the Carrel method is that if it breaks down it fails lamentably. It has never taken hold in a wide area of the French Army, and in England has rarely been accepted as the method of choice. The Carrel method has, in his judgment—"speaking with the utmost respect of the work that Carrel has done for many years past"—achieved its greatest successes in cases in which it need never have been used. A second method was introduced by Rutherford Morrison, and has been used by him for two years. It consists in the free, mechanical exposure of all parts of the wound, the scraping away of all granulation tissue, and the removal of all dead and seriously injured portions and all fragments of bone; then the wound is dried with gauze, and "a very thin smear of what Sir Rutherford calls by the perfectly hideous name of 'bipp' is applied to all the surfaces." Bipp consists of bismuth, one part; iodoform, two parts, and petrolatum, one part. The wound is then stitched up without drainage, immobilized, and left for ten days. These patients do amazingly well; but Sir Berkeley has found by much experience that they do equally well when he "bipps them without bipp." He has since persuaded Morrison to try treating some of his cases without bipp, and had his authority to say that they had done just as well without it as any he had ever treated with it. "With a patient sent back from France with a compound fracture, with suppuration beyond anything ever seen in civil life, these cases can be opened up, curetted, the dead bone removed, and in three weeks can be healed completely, the bone united without any antiseptic whatever having been in contact with the wound, either at the time of closure or at any other time." He thought it did not make much difference what was done to the wounds, provided there is a free, mechanical cleansing, and a careful, scrupulous, rigid technic.

In closing, Sir Berkeley said: "The question is still very open. The last thing that any one must do is to imagine that a method for treatment of wounds has finally, by the industry and immense capacity for research, been found either by Carrel or by Morrison or by Browning with his flavine compound, or by any one else. The one certain thing is that if you get your patient early, if you operate ruthlessly, taking away all dead and contaminated tissues, you will find that you can get an early and a perfect healing of that wound by first intention. And if you cannot get that early access to your patient, and see him only when a definite infection is soundly established in all parts of the wound, then again the essential thing is the free, mechanical exposure and cleansing of all parts of the wound; and having done that you may do such other things as you care to try. One method is as good as another, and no method the equal of any; but the two things that have come out from all this exhaustive inquiry and most painstaking care of patients is that the primary essential is freedom of exposure of all parts, thorough cleansing, and from first to last the most absolute immobility that you can impose on any wound of the parts. It is just as important, or more important, to immobilize as firmly and as rigidly as you can a wound of the soft parts of the body as a compound fracture of the bone."

DISCUSSION

Major George W. Crile, in discussing Sir Berkeley's paper, said that he had found practically all of his preconceptions concerning surgery to be wrong. The missiles produced the most extraordinary wounds; and the one that surprised him as much as any was that the supermud acted as a missile in itself. A high explosive shell would dive into the mud and throw the mud with such tremendous velocity that it would actually cause a penetration of the skin; and through that hole a vast amount of mud would be forced, producing a very bad type of wound, and in some instances death. He agreed with Sir Berkeley as to complete wound excision, and had found that the incision must be much larger than he had ever expected to make; but in time one gets to know that when the tissues cut in a certain way one has gone to a point at which there is a good resistance established. He reflected Sir Berkeley's opinion that physiologic resistance is the biggest single factor in the healing of the wound.

As to antiseptics, the Lakeside Unit took with it a complete outfit for carrying out the Carrel-Dakin technic, use it now in their base hospital, and have also thrown teams forward into the front area. Their experience has been practically the same as Sir Berkeley had intimated; if there is plenty of help and if well done, the wounds do beautifully. He had never seen any wounds do better than those in which a typical and perfect Carrel technic has been carried out from beginning to end without a slip. But the moment one is confronted with the problems presented in the front area, it is absolutely impossible to carry out any complicated technic. The period of contamination is the first twelve hours, and after that the wound goes into the period of infection. The patient should be operated on in the period of contamination, before infection begins. When he first heard of "bipp" there were three reasons why he doubted whether it would be good; first, it contained bismuth; second, it contained iodoform, and, third, it contained petrolatum. He was surprised to find that the patients did very well, but it is necessary to use it lightly and then give perfect physiologic rest. Like Sir Berkeley, he had found that they also do well without bipp. He was sure that the ideal antiseptic for war surgery had not been found. He thought it was true that for men who were carefully trained and taken away from all the problems of an ordinary civil existence, the work in the camp and the simple physiologic business of fighting were to the advantage of the men. These men become vigorous, and present an entirely different problem as to infections than the average civilian. Who would think in civil life of attacking a wound in the knee joint, washing it out with salt solution, and closing it up without drainage? As a matter of fact, 70 per cent. of the wounds so treated get on without any trouble whatever. In large chest wounds of all sorts and descriptions, they open the chest widely, take out foreign bodies and remove the blood, close up the wounds tight without drainage, and nearly all of them heal without any infection. They are not dealing with the same type of physiologic resistance in the well trained, selected individuals who are soldiers as they are accustomed to deal with in the civilian population. Gas gangrene has been practically mastered by learning that it attacks principally the muscles; if they are excised there is practically no spread of the disease. It has now almost disappeared from the acute casualties. In the wounded who lie out in "No Man's Land" for two or five or ten days, it has been found that the wounds that have done best are those that contain maggots. The reason for this is that there is devitalized tissue; the maggot lives on this devitalized tissue, and if it destroys that tissue it does in time what the surgical operation does. He believed it was in the power of General Gorgas to do the greatest task of surgery for our armies if he could carry out his plan to have our hospitals out near the front so that our soldiers can be brought in early, and receive the necessary care at the hands of good surgeons. That would amount to more than all the antiseptics one could muster in all the world.

Dr. Edward Martin, Philadelphia, said they had been advised by one eminent member of the profession to take all the antiseptics and throw them into the sea, and another had advised them to raise a brood of tame maggots to take care of wounds. What Sir Berkeley had done most of them could not do; what they were after was what they could do best for the good of the Army; and the majority still believed that there was a germicide that kills the germ and that was what they were after. They are still searching for the best and least injurious. Now Dakin thinks he has found it, and he has asked Lee to make a trial of his preparation; the results have been very good. They had been taken to the gentlemen of the Army and Navy, and they had detailed Dr. Furness and Dr. Lee to carry on the research. They had selected surgeons with large hospital and industrial plants, and the reports were enthusiastic with the exception of Boston—and that was in its favor. He advised that we await the outcome of these experiments before throwing away all antiseptics and treating every wound with courage and the knife and nothing else.

Dr. E. H. Dunham said that as a result of laboratory investigations it appears that there are three things to know about an antiseptic: the speed of disinfection, the stability of the antiseptic, and the degree of concentration in which that antiseptic can be used. There are three classes of hypochlorids: the Dakin solution, chloramin-T and dichloramin-T. Chloramin-T is soluble in water, and dichloramin-T is not. There is an enormous difference in the speed of disinfection, and that is an important element. The next point was the stability of the disinfection; the chlorid antiseptics are very unstable. He explained the action of the chlorins, and in closing said that if one could have a rapidly acting antiseptic that was not so unstable that it would keep up its action for a long time, it would be a real help.

Dr. W. Estell Lee, Philadelphia, reported 7,228 cases in which dichloramin-T has been used, and said it had also been used in many war wounds in France. From this clinical experience the conclusions offered in the first report had developed into firm convictions. Their experience shows that the chlorin preparations have proved superior to all other antiseptic preparations. However, if used for any length of time, they produced marked irritation of the skin; various modifications, therefore, were tried, and the best had been that suggested by Dakin. The original solution was very unstable, and had to be prepared almost daily. It contained such a small germicidal agent that it was necessary to have it at all times in contact with the wound. It was necessary frequently to renew the solution every two hours day and night. Most of these faults have been overcome by the development of a beautiful and complicated technic which consumes a great deal of time on the part of the surgeon and nurse, and an unnecessary expense for both apparatus and dressing material. They made a search for a new antiseptic, and Dr. Dakin had asked them to try out dichloramin-T. By the use of oil as a menstruum, a large amount was brought into contact with the infection in such a manner that it was slowly infused into the tissues; and during this period its action is in all respects equal to that of the chloramin compound. This eliminated at the start the necessity for the complicated Carrel technic. The results of these clinical tests have been the realization of Dakin's hopes.

Dr. Lee gave the results obtained in a vast number of wounds of various sorts, and showed lantern slides demonstrating the method of applying the solution and the dressings, emphasizing the economy in dressings required. By this means they are able to treat eighty patients in an hour at their clinic, and have handled 100 in an hour on certain occasions. They use less than one fourth of the gauze formerly used, less than one tenth of the bandages, and have cut down the time of healing from fourteen days to ten.

Dr. William O'Neill Sherman spoke in defense of the Carrel method, and said if the impression was allowed to prevail that antiseptics have no use there is no use in going to France. We could simply let them put on a bandage over there and send the boys home. He had spent five months in France and England, and every man in France and England was infected. Carrel's hospital was 8 miles back from the lines, but not a man was infected who had received this treatment, and there was not a drop of pus. He spoke of the work of Chutro, who had 300 beds in Paris and was using this method with good results. Dr. Sherman exhibited lantern slides showing wounds of various sorts at different stages under treatment by the Carrel method.

Evening Session, October 24

This session included the presidential address on "The Use of Radium in Gynecology," by Dr. John G. Clark, Philadelphia, and a symposium on "Military Surgery and the Specialties." The heads of the various special departments organized by the Surgeon-General's Office outlined the work that these departments expect to undertake, and described what has already been done.

Evening Session, October 25

Surgery of the Spinal Cord

Dr. Charles M. Frazier of Philadelphia read a paper on surgery of the spinal cord, dealing largely with the neurologic problems encountered. In discussing the paper, Dr. Allen B. Kanavel, Chicago, said he was well acquainted with the excellent course of instruction being given to the neurologic service, and was certain that before the war had begun for us we shall have a corps of men trained to do this work to the credit of the entire profession of America. He thought he could best discuss the subject by drawing attention to a few cases in which he has been permitted to perform a laminectomy. He showed lantern slides of several cases, and said he was convinced that the best time to operate was after the patient has recovered from shock.

Surgery of the Stomach

Major William J. Mayo, M. R. C., U. S. Army, Rochester, Minn., stated that 30 per cent. of all cancers of civilized man are in the stomach, and that this condition is uncommon in primitive man and in the lower animals, although there is no mechanical and secretory difference in the construction of the stomach. He believed that chronic gastric ulcer is not often cured medically, and is not seldom a source of cancer. He called attention to heat as a source of irritation, and was of the opinion that cancer occurs more frequently in man than in woman because man is in the habit of taking his food and beverages hotter than the average woman does. Woman sits at the foot of the table and pours the tea and coffee, serving the men of the household first and drinking hers after it has cooled somewhat. In the Chinese the same rule holds true with the rice that is eaten, for the women eat at the second table.

In closing, he said that food and drink should not be taken into the stomach hotter than can be borne comfortably in the mouth. The mouth and the throat are protected by sensitive nerves, but the stomach is not. Early diagnosis of cancer depends on the roentgen examination. The antecolonic end to side anastomosis between the stomach and jejunum greatly accelerates closure. The results of operation for cancer of the stomach are now fairly good and are improving; 38.4 per cent. are cured.

DISCUSSION

Dr. A. J. Ochsner, Chicago, said we were impressed at once with the fact that a condition to which every one is exposed is an important condition in the production of this most fatal of all diseases. We have known for a long time that there is no superficial cancer anywhere which occurs without preliminary irritation, and that this preliminary irritation gives rise to disturbed circulation. He was of the opinion that human beings are afflicted with cancer because they are manure eaters. We fertilize our soil, and in that way take unclean food into the stomach which produces an irritation. Cancer occurs most frequently at the point at which there is interference with the circulation, and he was convinced that this was a large factor in its production; and that smoker's cancer occurred most often on the lower lip because the circulation was interfered with owing to the weight of the pipe. Although we have not yet found the organism that causes it, we have found the condition that makes it possible for this agent to live successfully under these conditions. He thought we should endeavor to avoid all irritation, stop boiling our insides, and at the same time insist on having clean food to put inside the alimentary canal. He was sure that when that was done there would be an enormous decrease in the amount of cancer.

Dr. L. L. McArthur, Chicago, agreed with Dr. Mayo that irritation was a predisposing cause to cancer, and was convinced that irritation made a doorway through which the infective element finally gains access. This atrium he has called attention to in various ways. He was sufficiently neutral to call Dr. Mayo's attention to the fact that the male stomach in Germany has the same frequency of infection as the female, and yet in Germany the man sits at the foot of the table and pours the tea and has his cold. Cancer of the skin has been shown to be due to the yeast plant, and has been sloughed off from the great group known as cancer proper. He thought the great lesson to be learned was that the operation formerly considered as formidable is being lessened, and that the extent of the operation continually grows. When hearing Dr. Mayo's remarkable statistics that 38.4 per cent. were cured in the understanding of the term that for three years they have lived and were free from evidence of other disease, we are not to deduce the fact that this represents the mortality of the stomach when operated on, but only as the mortality which followed selected cases—not cases selected to improve the statistics to be presented to a medical society, but selected cases in which operation can be performed with reasonable hope of success. The diagnosis is very difficult in many cases even after the abdomen is opened, and when the diagnosis is made, even then the prognosis cannot be accurately prognosticated.

He called attention to an operation for putting the stomach at rest after operation, especially in cases of cancer of the stomach complicated with gallstones, by inserting a tube into the gallbladder and bringing it outside the abdomen. In this way the bile is prevented from getting into the bladder, salt solution can be introduced into the duodenum, the intestines can be flooded, and the patient can be made much more comfortable.

War Surgery of the Lungs and Pleura

Sir Berkeley Moynihan, Leeds, England, read an exceedingly interesting paper on this subject, recounting the experience of himself and others, from which he drew the following conclusions:

1. The approximate mortality from gunshot wounds of the chest, after the patients get into the hands of the doctors, is 20 per cent.
2. Causes of death are hemorrhage, as a rule within from eighteen to forty-eight hours, sepsis beginning after the third or fourth day.
3. Local conditions in the wounds of the chest wall and lung are in all respects similar to those in wounds elsewhere; the missiles are the same, destructive elements the same, and infective organisms the same.
4. The lung tissue is more resistant to attack than many other tissues. The opening of the cavity and the exposure of the contents add a danger of the most threatening character.
5. The chief essential in the treatment of all penetrating wounds of the chest is rest.
6. In clean wounds of the chest, rest together with dressing of the wounds of entrance and exit will lead to recovery in the great majority of cases.
7. In cases of open thorax, the earliest and most complete effort must be made to secure closure of the wound.
8. In grave cases of hemorrhage when blood escapes from the wound, the wound in the lung must be treated by suture or by plugging of the cavity from which the blood escapes.
9. When the blood is sterile and remains so, no operative procedure is necessary.
10. In cases of hemothorax in which the blood remains sterile, aspiration after the tenth day certainly hastens convalescence and permits expansion of the lung and free movements.
11. In cases of hemothorax, whether the amount of blood is small or large, when infection takes place operation is necessary. Early operation, whether the Carrel or the Morrison method is adopted, saves many weeks of convalescence and permits functional recovery.
12. Small rifle bullets or other projectiles in the lung often cause no symptoms, and may be safely removed.
13. Large foreign bodies may cause symptoms, and in such cases they should be removed. Pieces of metal so removed, whatever the period of time has elapsed since their introduction into the wound may be, are almost always found to be infected.

ORDERS TO OFFICERS OF THE MEDICAL CORPS

Alabama

To Atlanta, Ga., Medical Supply Depot, for duty as assistant, Capt. ROBERT E. HALE, Bellamy.

To Camp Dix, Wrightstown, N. J., for duty from Fort Oglethorpe, Lieuts. MOSES E. SHERRER, [illegible]; MANNIE A. FORT, Grand Bay; FRANK H. McCONNICO, [illegible]; JOHN F. JENKINS, GILMER H. MOORE, Opelika; JULIUS F. PEAVY, JR., Robertsdale; JAMES W. BEARD, Troy; MAXWELL MOODY, Tuscaloosa; BRYANT B. EDWARDS, Union Springs.

To Camp Gordon, Atlanta, Ga., for duty from Fort Oglethorpe, Lieuts. WILLIAM C. DABNEY, Birmingham; FRANK W. YOUNG, Hartford.

To Camp Hancock, Augusta, Ga., for temporary duty, from Fort Oglethorpe, Lieut. JULIAN K. LEGARE, Forkland.

To Camp Jackson, Columbia, S. C., for temporary duty, Lieut. WILLIAM E. SHERMAN, Albertville.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieuts. ANDREW L. GLAZE, JR., Athens; CHARLES W. BRASFIELD, Linden; JAMES P. VANSANT, Piedmont; DANIEL W. WARD, Tuscaloosa.

To Camp Pike, Little Rock, Ark., for duty from Fort Oglethorpe, Lieuts. SOLON W. WRIGHT, Bessemer; ORLANDO V. LANGLEY, Loachapoaka; CHARLES D. MASON, Scottsboro; JAMES H. SOMERVILLE, JR., Tuscaloosa.

To Camp Upton, Yaphank, L. I., for duty, from Fort Oglethorpe, Lieuts. BEAMAN S. COOLEY, Boaz; WILLIAM A. SEWEL, Center; HORACE VAN DE VOORT, Gastonburg; WALTER E. ALLEN, Ward.

To Camp Wheeler, Macon, Ga., and report to commanding officer of the base hospital for temporary duty, Lieut. EDWARD C. HAGLER, Northport.

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Capt. WILLIAM H. OATES, Mobile; Lieut. AUSTIN F. J. BOYD, Emelle.

To Fort Oglethorpe, for instruction, Lieut. WILLIAM M. CAFFEE, Edgewater.

Arizona

To Fort Oglethorpe, for instruction, from School of Military Roentgenology, Los Angeles, Capt. WILLIAM H. SARGENT, Phoenix.

Arkansas

To Camp Dix, Wrightstown, N. J., for duty, from Fort Oglethorpe, Lieuts. MORGAN C. BERRY, Donaldson; ROBERT E. WEAVER, Hope.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. IRA W. ELLIS, Monette.

To Camp Grant, Rockford, Ill., for duty in the division of ophthalmology, section of surgery of the head, Capt. JOHN H. HARVEY, Waldron.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieut. JOHN B. WELLS, Scott.

To Camp Upton, Yaphank, L. I., for duty, from Fort Oglethorpe, Lieut. EDWARD R. COTHAM, Monticello.

To Rockefeller Institute, New York, N. Y., for a course of instruction in laboratory work, from Fort Oglethorpe, Lieut. JOHN C. SIMPSON, Hamburg.

California

To Army Medical School, Washington, D. C., Lieut. CLYDE E. SHEDD, San Francisco.

To Camp Greene, Charlotte, N. C., base hospital for temporary duty, Capt. GUSTAV J. BERGENER, San Francisco.

To Camp Kearny, Linda Vista, Calif., for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, Lieut. OSCAR O. YOUNG, Garden Grove.

To Camp Lee, Petersburg, Va., for duty in his specialty, Major JAMES R. MOORE, Los Angeles.

To Fort Bayard, N. M., for duty, Lieut. ROBERT C. KIRKWOOD, Alta.

To Fort Oglethorpe for instruction, Capt. THOMAS W. O'REILLY, Los Angeles; Lieut. ANDREW B. WESSELS, San Diego.

To Letterman General Hospital, San Francisco, Calif., for duty in his specialty, Capt. FREDERICK E. ALLEN, Hayward.

To Los Angeles, Calif., for a course of instruction in military roentgenology, Lieut. ORRIN S. COOK, San Francisco.

To New York, N. Y., for orthopedic instruction, from Army Medical School, Washington, D. C., Lieut. JOSEPH R. JONES, Yreka.

To report by telegraph to the commanding general, Western Department, for assignment to duty, Capt. HENRY E. MORRISON, Dixon; Lieut. LOUIS A. FRARY, Oakland.

To the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, from Camp Kearny, Lieut. HARRY F. WORLEY, San Diego.

Colorado

To Honolulu, Hawaii, Dept. Hospital for duty, from Schofield Barracks, Lieut. RAY L. DRINKWATER, Denver.

Connecticut

To Camp Cody, Deming, N. M., for duty in connection with orthopedic work, Capt. JAMES C. WILSON, Hartford.

To Camp Devens, Ayer, Mass., for temporary duty, Capt. FRANK P. TODD, Danielson; for duty, from Fort Benjamin Harrison, Lieut. ULRIE PLANTE, Hartford.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. FRANCIS J. CARROLL, Bridgeport.

To Fort Oglethorpe, for instruction, Capt. JAMES L. MORIARITY, Waterbury.

District of Columbia

To Camp Dix, Wrightstown, N. J., for duty from Fort Oglethorpe, Lieuts. CHARLES BELL, Washington, D. C., WILLIAM O. WETMORE, Washington, D. C.

To Camp Sevier, Greenville, S. C., for duty from Fort Oglethorpe, Lieut. GEORGE Y. MacMURPHY, Washington, D. C.

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Lieuts. HOWARD W. BARKER, Washington, D. C.; HARRY M. PRICE, Washington, D. C.

To Philadelphia, for a course of instruction in orthopedic surgery, Lieut. JOEL A. TILTON, Washington, D. C.

To Washington, D. C., and report to the Surgeon-General of the Army for duty in his office in connection with the division of brain surgery, section of surgery of the head, Lieut. HARRY H. KERR, Washington, D. C.

Florida

To Camp Dix, Wrightstown, N. J., for duty from Fort Oglethorpe, Lieuts. JOHN M. WHITFIELD, Malone; HAROLD M. BEARDAL, Orlando; FRANK P. HIXON, Pensacola; DREW R. HANDLEY, Raidford; EARLE H. McRAE, Tampa.

To Camp Greene, Charlotte, N. C., for temporary duty, from Fort Oglethorpe, Lieut. GASTON DAY, Jacksonville.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieuts. DWIGHT G. RIVERS, Lake City; BALDWIN S. STUTTS, Pt. St. Joe.

To Camp Meade, Annapolis Junction, Md., for duty from Fort Oglethorpe, Lieuts. HARRY C. GALEY, Key West; DANIEL B. WILLIAMS, South Jacksonville.

To Camp Pike, Little Rock, Ark., for duty, from Fort Oglethorpe, Lieut. CHARLTON C. WHITTLE, Nocatee.

To Camp Upton, Yaphank, L. I., for duty from Fort Oglethorpe. Lieuts. JOHN D. GRIFFIN, Lakeland; RICHARD LEFFERS, Lakeland.

To Camp Wheeler, Macon, Ga., for duty, Lieut. NECY L. GACHET, Century.

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Lieut. ARCHIE C. WATSON, Live Oak.

To Linda Vista, Camp Kearny, Calif., for temporary duty, from Camp Cody, Deming, N. M., Capt. RAYMOND B. McLAWS, Tampa.

To Mincola, L. I., Hazelhurst Field, for duty with the 201st Aero Squadron, Lieut. JAMES L. PENNINGTON, Fountain.

Honorably discharged from the Medical Reserve Corps of the Army on account of being physically disqualified for active service, Lieut. DANIEL M. ADAMS, Panama City.

Georgia

To Camp Gordon, Atlanta, Ga., for duty from Fort Oglethorpe, Lieuts. STEPHEN T. BROWN, Atlanta; JAMES H. BUTLER, Augusta, Ga.; WHITFIELD W. CROOK, Cuthbert; LOWNDES W. SHAW, Savannah.

To Camp Lee, Petersburg, Va., for duty from Fort Oglethorpe, Lieuts. LESLIE L. BLAIN, Marietta; HUGH W. WADE, Quitman.

To Camp Meade, Annapolis Junction, Md., for duty from Fort Oglethorpe, Lieuts. A. NATHAN DYKES, Columbus; JOHN F. BURKHALTER, Morven; HARRY C. WILLIS. Rome.

To Camp Pike, Little Rock, Ark., for duty, from Fort Oglethorpe, Lieuts. DeLAMAR TURNER, Milledgeville; BURTON P. BRADLEY, Rome.

To Camp Wheeler, Macon, Ga., for temporary duty, from Fort Oglethorpe, Lieut. CYRUS K. SHARP, Arlington.

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Lieut. JAMES T. CALLOWAY, Atlanta.

To Mincola, L. I., Hazelhurst Field, for duty with the 200th Aero Squadron, relieved from present duties at this Field, Lieut. THOMAS E. BLACKBURN, Swainsboro.

To Philadelphia, for orthopedic instruction, from Fort Oglethorpe, Lieut. EVERARD A. WILCOX, Augusta.

To Camp Pike, Little Rock, Ark., for duty, from Fort Oglethorpe, LEROY UMBURN, Albion; JAMES W. SILLIMAN, Bradenville; IGNATIUS A. BEDNARKIEWICZ, Erie; JOHN H. LLOYD, Erie; LAWRENCE N. BREENE, Farrell; ARTHUR E. BOGART, Philadelphia; BENJAMIN WEINER, Pittsburgh.

To Camp Sevier, Greenville, S. C., for temporary duty, from Fort Oglethorpe, Capt. MATTHEW J. SHIELDS, Scranton; Lieut. GEORGE S. DEIBERT, Allentown; HEISTER V. HOWER, Scranton.

To Camp Upton, Yaphank, L. I., for duty, from Fort Oglethorpe, Lieuts. FRANK L. BAUM, Athal; JAMES R. SMITH, Erie; PAUL TIDENCE YOUNG, Erie; JOHN H. HUMES, McKees Rocks; SAMUEL H. PETTLER, New Brighton; JACOB L. ENGLE, Philadelphia; FREDERICK C. PETERS, Philadelphia; AUGUST G. HINRICHS, Pittston; EARL C. WAGNER, Wilkes-Barre.

To Camp Wadsworth, Spartanburg, S. C., for temporary duty, from Fort Oglethorpe, Lieut. FRANK A. BRIDGETT, Philadelphia.

To Camp Wheeler, Macon, Ga., for temporary duty, from Fort Oglethorpe, Lieuts. JOHN J. HISLOP, Miners Mills; PERCY H. SHAW, Philadelphia.

To Chickamauga Park, Ga., for duty, from Fort Oglethorpe, Lieuts. THOMAS O. WILLIAMS, Brooklyn; HERBERT E. SIMRELL, Clark's Summit; ELMER HESS, Erie; RICHARD L. McNEER, Philadelphia; EDMOND R. LETT, Fallassee; MARTIN W. FREAS, United; GEORGE K. STRODE, Westchester.

To Cornell Medical College, New York, for a course of instruction in military roentgenology, Lieut. BOYD E. WILKINSON, Trevorton.

To Fort Oglethorpe, for instruction, from Jefferson Hospital, Philadelphia, Lieuts. W. LATIMER S. LANDES, Philadelphia; JAMES W. LEVERING, Philadelphia; WILLIAM H. G. MacKAY, Philadelphia; LOUIS R. WILEY, Philadelphia; JOHN E. LIVINGOOD, Womelsdorf.

To Philadelphia, for a course of instruction in orthopedic surgery, from Army Medical School, GEORGE H. FAGGART.

To Pittsburgh, for instruction in military roentgenology, from Fort Benjamin Harrison, Lieut. EDWIN P. BUCHANAN, Pittsburgh.

To Rockefeller Institute, for a course of instruction in laboratory work, from Fort Oglethorpe, Lieuts. JOHN W. GOODSELL, New Kensington; PHILIP F. WILLIAMS, Philadelphia; ERNEST J. ATEN, Pittsburgh.

To his home and the inactive list of the Medical Reserve Corps of the Army, Capt. FREDERICK PROESCHER, Pittsburgh.

Rhode Island

To Camp Dodge, Des Moines, Ia., for duty in the base hospital laboratory, from Rockefeller Institute, JAMES HAMILTON, JR., Providence.

South Carolina

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Capt. ISADORE SCHAYER, Columbia.

To Camp Gordon, Atlanta, Ga., for duty from Fort Oglethorpe, Lieut. WILLIAM B. ACKERMAN, Walterboro.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieuts. FITZHUGH P. SALLEY, Buffalo; CLARENCE D. JACOBS, Kingstree; FRANK M. HARVIN, Pinewood.

To Camp Meade, Annapolis Junction, Md., and report to the commanding officer of the base hospital, for temporary duty, relieved from present duties at this camp, Lieut. HERBERT H. HARRIS, Anderson; for duty, Lieut. LACY W. CORBETT, Bishopville.

To Camp Upton, Yaphank, L. I., for duty from Fort Oglethorpe, Lieuts. THOMAS M. MOORE, Hagood; WILLIAM J. BURDELL, Lugoff.

South Dakota

To Camp Logan, Houston, Tex., for duty in charge of the division of ophthalmology, section of surgery of the head, from Camp Gordon, Atlanta, Ga., Lieut. DENNIS F. O'CONNOR, Elkton.

To Camp Meade, Annapolis Junction, Md., for duty from Fort Oglethorpe, Lieut. ARCHIE McCALLISTER, Crow Creek.

To Kelly Field, South San Antonio, Tex., for duty, from Fort Riley, Lieut. SIGFRED ENGH, White Rock.

Tennessee

To Camp Cody, Deming, N. M., for duty in the base hospital laboratory, from Rockefeller Institute, Lieut. GEORGE L. BROWN, Memphis.

To Camp Dix, Wrightstown, N. J., for duty, from Fort Oglethorpe, Capt. OTEY J. PORTER, Columbia; Lieuts. LEON D'CASTO COTTEN, Alexandria; GUY C. ANDERSON, Eads; JOHN G. SEAY, Germantown; WILLIAM G. SAUNDERS, Jackson; FREDERICK W. LEE, Springfield.

To Camp Lee, Petersburg, Va., for duty from Fort Oglethorpe, Lieuts. WILLIAM R. BOOHER, Bristol; WILLIAM H. BALLARD, Laconia; WILLIAM D. CAGLE, Lobelville; CHARLES W. BROWN, Nashville; ROBERT L. DOSSETT, Tullahoma.

To Camp Meade, Annapolis Junction, Md., for duty from Fort Oglethorpe, Lieuts. LAWRENCE L. KELLER, Memphis; JOHN H. MORRIS, Pulaski.

To Camp Pike, Little Rock, Ark., for duty, from Fort Oglethorpe, Lieuts. WILLIAM C. SAIN, Bolivar; DAVID A. WALKER, Friendship; THOMAS H. INGRAM, Memphis; FRANCIS M. BOYATT, Oneida.

To Camp Sevier, Greenville, S. C., for temporary duty, from Fort Oglethorpe, Lieut. FLEETWOOD BRUBER, Nashville.

To Camp Upton, Yaphank, L. I., for duty from Fort Oglethorpe, Lieuts. HARRY E. HALL, Apison; E. GACOVIA MAXWELL, Darden.

To Phipps Clinic, Baltimore, Md., for intensive training in his specialty, from Fort Oglethorpe, Lieut. GEORGE A. HATCHER, Nashville.

To Washington, D. C., and report in person to the commanding officer, Quartermaster Repair Unit No. 1, for duty, from Army Medical School, Lieut. WILLIAM V. PRUETT, Brownsville.

To the inactive list of the Medical Reserve Corps from duty at Camp Wadsworth, Lieut. THOMAS W. RHODES, Whiteville.

Texas

To Army Medical School, for a course of instruction from Fort Sam Houston, Tex., Lieut. WILLIAM E. NESBIT, San Antonio.

To Boston, Mass., for instruction in orthopedic work, and upon completion of this course to return to the inactive list of the Medical Reserve Corps, Major CHARLES S. VENABLE, San Antonio.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. EUGENE M. PARRISH, Dallas.

To Camp MacArthur, Waco, Tex., for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, Capt. ISIDORE S. KAHN, San Antonio.

To Richmond Medical College, Richmond, Va., for a course of instruction in military roentgenology, Capt. WILLIAM R. FICKESSEN, San Antonio.

To Rockefeller Institute, for a course of instruction in laboratory work, Lieut. RICHARD C. CURTIS, Temple.

Vermont

To Camp Lee, Petersburg, Va., for duty with the Engineer Service Battalions, from Fort Benjamin Harrison, Lieut. FRANK L. GILBERT, Grafton.

To Camp Vail, Little Silver, N. J., for duty with the Signal Corps, from Fort Benjamin Harrison, Lieut. WALTER F. McKENZIE, Burlington.

To Syracuse, N. Y., Reorganization Camp, for duty, from Fort Ontario, N. Y., Lieut. VICTOR P. GENGE, Newport.

Virginia

To Camp Dix, Wrightstown, N. J., for duty, from Fort Oglethorpe, Lieuts. CHARLES A. YOUNG, Gore; MERIWETHER L. ANDERSON and JAMES G. BOISSEAU, Richmond.

To Camp Doniphan, Fort Sill, Okla., for duty in the base hospital laboratory, from Rockefeller Institute, Capt. ERASMUS G. HOPKINS, Richmond.

To Camp Lee, Petersburg, and report to commanding general, Eightieth Division, for duty, relieved from present duties at this camp, Capt. HUGH T. NELSON, JR., Charlottesville; Lieuts. WILLIAM F. MERCHANT, Manassas; HARRY R. SEELINGER, Norfolk; for duty, from Fort Oglethorpe, Lieut. WILLIAM F. PASSER, City Point; for temporary duty, Lieut. CARROLL E. FOLEY, Lovettesville.

To Camp Pike, Little Rock, Ark., for duty from Fort Oglethorpe, Lieut. WILLIAM A. LUCAS, Toms Creek.

To Camp Upton, Yaphank, L. I., for duty from Fort Oglethorpe, Lieuts. OLIVER F. BLANKINGSHIP, Richmond; WALTER C. TROW, Warrenton.

To Chickamauga Park, Ga., for duty from Fort Oglethorpe, Lieut. JAMES M. DAVIS, Westboro.

To Fort Oglethorpe for duty, Major WILLIAM J. BELL, Bristow, for instruction from school of military roentgenology at Richmond, Lieuts. CHARLES L. RUDASILL and HENRY S. STERN, Richmond.

To Fort Ontario, N. Y., for duty with Field Hospital No. 28, from Fort Benjamin Harrison, Lieut. JOHN C. PHILLIPS, Portsmouth.

To Philadelphia, for orthopedic instruction, from Fort Oglethorpe, Capt. HOWARD FLETCHER, Fairfax.

To Richmond Medical College, Richmond, for a course of instruction in military roentgenology, Lieut. FREDERICK P. FLETCHER, Richmond.

Washington

To Camp Lewis, American Lake, Wash., for duty in the orthopedic service, Capt. EDWARD A. RICH, Tacoma; to report to the commanding officer of the base hospital for duty in the genito-urinary and dermatologic section of the base hospital, relieved from other duties at this camp, Lieut. ALEXANDER H. PEACOCK, Seattle.

West Virginia

To Camp Dix, Wrightstown, N. J., for duty, from Fort Oglethorpe, DENNIS B. JARRELL, Woodville.

To Camp Gordon, Atlanta, Ga., for duty, from Fort Oglethorpe, Lieut. RICHARD H. EDMUNDSON, Morgantown.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieuts. FRANK J. BROSCHART, Marting; CHARLES S. COWIE, Martinsburg.

To Camp Pike, Little Rock, Ark., for duty, from Fort Oglethorpe, Lieuts. CLYDE A. HARPER, Amma; REECE M. PEDICORD, Elm Grove; EMERSON MEGRAIL, Wheeling.

To his home and return to the inactive list of the *Medical Reserve* Corps on account of being physically disqualified for active service, Lieut. CHARLES F. MAHOOD, Alderson.

Wisconsin

To Camp Grant, Rockford, Ill., for temporary duty, Lieut. JOHN E. MULSAW, Two Rivers.

To Fort Snelling, Minn., and report to the commanding officer for duty as assistant surgeon, relieved from present duties at this camp, Capt. ROBERT M. NICHOLS, Sheboygan.

To Kelly Field, South San Antonio, Tex., for duty, from Fort Riley, Lieut. GEORGE S. DARBY, Brodhead.

To Sparta, Wis., Camp Robinson, for duty, Lieut. JOHN W. HANSEN, Milwaukee.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Chicago

Personal.—Dr. Heman H. Brown was elected president of the Michigan Society of ,Chicago at its annual meeting, October 27.

Hospital Contract Let.—A contract to build a new wing to the Contagious Disease Hospital was awarded, October 27, for $374,900.

Billings Tells of Russian Experiences.—A testimonial banquet was given by the Physicians' Club of Chicago, in honor of Dr. Frank Billings, at the Auditorium Hotel, November 1. Dr. Augustus O'Neill acted as toastmaster. A silver loving cup was presented to Dr. Billings on behalf of the Physicians' Club.

County Hospital Branch.—Circulars advising voters to vote for the proposition to spend a million dollars for the erection of a Branch County Hospital at Ninety-Fifth and State streets have been sent out by the Branch Association of the County Hospital, which urges the great need for this institution.

Canadian Surgeon-General in Chicago.—Surg.-Gen. John T. Fotheringham, C.A.M.C., K.M.G., who went to France in 1914, with the first Canadian contingent, and was in active service in France until April of this year, when he was made Surgeon-General of Canada, was the guest of honor of the Institute of Medicine of Chicago at its meeting, held November 2, at the LaSalle Hotel, where he delivered an address on "Modern Methods in War from a Medical Standpoint." After the address a buffet supper was served.

IOWA

Hospital News.—The Bertha M. Parsons Building of the Iowa Congregational Hospital Association, Des Moines, was dedicated, October 23. The building is four stories in height, of brick, fireproof, and will accommodate fifty patients.——The 240 acres of land adjacent to the city limits of Shenandoah, making up the bulk of the gift for a memorial hospital by Mrs. Catherine Hand, were sold, October 18, for $65,040.

Southeastern Physicians Elect Officers.—The annual meeting of the Southeastern Iowa Medical Association was held at Fairfield, October 18. Washington was selected as the next place of meeting, and the following officers were elected: president, Dr. James S. Gaumer, Fairfield; vice president, Dr. Elias B. Howell, Ottumwa; secretary-treasurer; Dr. Carl W. Wahrer, Fort Madison, and censors, Drs. Otto A. Geeseka, Mount Pleasant; George W. Hay, Washington, and Samuel K. Davis, Libertyville.

MARYLAND

Personal.—Capt. Alexander D. McConachie, M. R. C., U. S. Army, has left for Plattsburg, N. Y., where he will be in charge of the eye, ear and throat surgical section of the base hospital.——Dr. William S. Thayer, Baltimore, who went to Russia with the Red Cross unit, is in charge of the Red Cross work in Petrograd. He has seventeen men assisting him.——Dr. Archibald C. Harrison, who recently underwent abdominal section at St. Joseph's Hospital, Baltimore, is reported to be convalescent.——Dr. Richard F. Kieffer, Baltimore, who is on duty with a hospital unit on the western front, has recovered from a severe attack of fever.

Physicians Endorse New City Charter.—The Physicians' Civic Club of Baltimore, after a full discussion, has unanimously endorsed a movement to secure a new charter under the Home Rule Amendment. Eighteen years ago the city adopted a charter which earned for itself the title of "Baltimore's Model Charter." Today the charter is out of date. Since its adoption every city but one in the country has changed its charter, incorporating various modern features for securing greater efficiency and greater responsiveness to the will of the people. The physicians stand back of this movement, and will advocate a new charter board to study the needs of Baltimore at the election, November 6.

MASSACHUSETTS

Health Association Meeting.—The regular quarterly meeting of the Massachusetts Board of Health was held in Pittsfield, October 25. The topics considered at the meeting were "The Importance of Modern Public Health Work," "The Work of the Committee on Public Health of Massachusetts Medical Society," "Rural Sanitation," "Industrial Hygiene," "Child Conservation in Time of War," and "Rats, Insects, and Public Enemies."

MINNESOTA

Personal.—Dr. Ernest W. Cowern, North St. Paul, has been appointed physician of Ramsey County. The position carries no salary, and Dr. Cowern is the first man to be officially appointed in ten years.

Minnesota Eye, Ear and Throat Men Elect Officers.—At the annual meeting of the Minnesota Academy of Ophthalmology and Oto-Laryngology, held in St. Paul, the following officers were elected: president, Dr. Frank E. Burch, St. Paul; vice presidents, Drs. James S. Reynolds, Minneapolis, and Conrad W. Wilkowske, Chippewa Falls, Wis., and secretary-treasurer, Dr. John H. Morse, Minneapolis.

New Officers.—At the annual meeting of the St. Louis County Medical Society of Duluth, October 19, Dr. Arthur N. Collins, Duluth, was elected president; Dr. John H. Crowe, Virginia, vice president, and Dr. Charles H. Schroder, Duluth, secretary-treasurer (reelected).——At the annual meeting of the Minnesota Public Health Association, held in St. Paul, the following officers were elected: president, Dr. W. L. Beadie, St. Paul; vice presidents, Mrs. J. R. Brandrup and Mrs. A. L. Robinson; secretary, Dr. Edward L. Tuohy, Duluth, and treasurer, Mr. W. A. Laidlaw. The organization proposes to change from an association to a corporation.

Nurses and the Red Cross Seal Campaign.—In 1916, according to the *Minnesota Public Health Association Journal*, the contribution of the state to the Red Cross and to the Red Cross Seal Campaign was $40,000. It is expected this year that it will amount to $60,000. Through an arrangement with the Public Health Association, each town in the state selling a certain number of seals was entitled to the services of a public health nurse for a period of from one week up, depending on the number of seals sold. Sixty-four towns in 1916 had nurses under this arrangement. The services of the nurse proved so satisfactory in these communities that in almost every instance she was retained an additional week at the expense of the community. For the 1917 campaign, a nurse experienced in all branches of public health work will be furnished free for one week to any community for each 7,000 seals sold. A physician experienced in public health work will be furnished, to any community, with all necessary supplies, for one week for every 20,000 seals sold. This physician will make an intensive health survey, a sanitary survey, school, medical supervision, do infant welfare work, or all of these combined.

NEBRASKA

New Hospital.—Dr. Herschell B. Cummins has recently opened the Seward Hospital, located in the southeast part of Seward.

Lincoln Medical Women Organize.—The women physicians of Lincoln and vicinity have organized the Medical Women's Club of Lincoln, and elected Dr. Daisy M. Hansen, president, and Dr. Laura J. Brown, secretary.

Free Service to Soldiers.—At the annual meeting of the Buffalo County Medical Society, held at Kearney, October 15, it was voted to give free surgical service to men rejected for the Army or Navy of the United States because of minor defects. Dr. Charles K. Gibbons, Kearney, was elected president; Dr. Raymond L. Hart, Amhurst, vice president, and Dr. Joseph L. Bennett, Kearney, secretary-treasurer.

University Hospital Dedicated.—The teaching hospital of the University of Nebraska College of Medicine was dedicated with appropriate ceremonies, October 17, the principal speaker being Chancellor Avery of the university. The new structure, now in full operation with a capacity of 119 beds, was made possible by three legislative appropriations, $150,000 for the building, $65,000 for equipment, and $100,000 for biennial maintenance.

Personal.—Dr. Maurice I. Smith, for several years connected with the department of pharmacology of the University of Michigan, Ann Arbor, has been placed in charge of the department of pharmacology in the College of Medicine in the University of Nebraska, Omaha; Dr. J. A. Kittleson of the University of Minnesota has been appointed professor of anatomy, and Dr. S. A. Rubnitz, instructor in biochemistry.——Dr. Edwin C. Henry, Omaha, has been appointed chief surgeon of the Orthopedic Hospital, Lincoln, during the absence of Dr. J. L. Lord, in the military service.——Dr. J. W. Brendell, Avoca, fractured his wrist, October 6, while cranking his motor car.

NEVADA

State Society Meeting.—The Nevada State Medical Association held its fourteenth annual meeting at Reno, October 18 and 19, under the presidency of Dr. Raymond St. Clair, Reno, and elected the following officers: president, Dr. Henry A. Brown, Reno; vice presidents, Drs. Martin A. Robinson, Reno, and John A. Ascher, Sparks; secretary-treasurer, Dr. John L. Robinson, Reno; trustee, Dr. George L. Servoss, and delegate to the American Medical Association, Dr. William Z. Dahl, Reno.

NEW JERSEY

New County Officers.—At the annual meeting of the Salem County Medical Society, held in Salem, October 10, the following officers were elected: Dr. Henry T. Johnson, Pedricktown, president; Dr. Carey L. Lamborn, Penns Grove, vice president, and Dr. John F. Smith, Salem, secretary-treasurer.

Personal.—Capt. William J. Condon, M. R. C., U. S. Army, New Brunswick, was acquitted, October 27, on the charge of murdering John V. Piper, a student at Rutgers College.——Dr. Edward A. Y. Schellenger has resigned as a member of the board of managers of the Camden County Tuberculosis Hospital, Ancora, and Dr. Edwin C. Pechin has been appointed in his place.——Dr. R. Mills Smith, Camden, October 17, was awarded $1,140 damages for injuries sustained in a grade crossing collision on the Atlantic City Railroad, at Gloucester.

NEW YORK

Personal.—Dr. William E. Gorton, for twenty years a member of the Corning Board of Education, and for the past seven years its president, has resigned, and Dr. E. Eugene Sullivan, Elmira, has been appointed his successor.

Medical Inspectors and Physical Educators' Association.—This organization will hold its next meeting at a place to be designated at one of the sessions of the Section on Hygiene and Physical Education of the New York State Teachers' Association at Syracuse, November 26-28. The purpose of this meeting is to elect officers for the following year and to vote on the constitution of the association.

New York City

Brooklyn Districted.—The health department, January 1, will put into effect its new method of local administration in Brooklyn. This involves the division of the city into fourteen health districts, each with an official in charge, who will report to the city health commissioner.

Microscopic Exhibit.—The New York Microscopical Society will give its annual exhibition at the American Museum of Natural History, November 3, in the evening. In addition to slides of interest in the arts, sciences and industries, there will be a demonstration by the department of health of practical use of the microscope in safeguarding public health.

Eastern Pediatric Societies to Meet.—The combined meeting of the New England Pediatric Society, the Philadelphia Pediatric Society and the Section on Pediatrics of the New York Academy of Medicine will be held in New York City, November 8. There will be clinics during the day, a dinner at the Harvard Club, and after dinner talks on the pediatrician's part in the war.

The Health Department and the Milk Problem.—Loose milk is sold in this city as it has been for years in conformity with regulations of the department of health. A statement made by the department of health emphasizes the fact that the great reduction in infant mortality in this city in recent years is to a large extent due to the general recognition that the only safe milk for babies is Grade A bottled milk. The Bureau of Public Health Education of the department of health is preparing a poster which contrasts the relative costs and food values of milk at 14 cents a quart, porterhouse steak at 35 cents a pound, and eggs at 60 cents a dozen. This shows that even at present prices milk is by far the cheapest of building foods.

Law Does Not Protect Women in New Employments.—A recent *Bulletin* of the department of health relates that an investigation of the conditions under which women elevator operators work, which has just been made by the Division of

Industrial Hygiene, shows that in some instances the conditions under which the women work are insanitary and the hours long; in one instance the night operator was on duty for fifteen hours, less an hour for midnight lunch. These investigations have brought out the fact that the state labor laws regulating the conditions of employment for women only provide for a regulation of conditions of employment of women in factories, shops and stores. The department of health intends to keep the apartment houses where undesirable conditions have been found under observation, and to find a way of safeguarding the health of these women.

Prenatal Instruction to Mothers.—A recent communication from the health department of New York City points out that if a further definite impression is to be made in the infant mortality rates it must come through concerted efforts to reduce the deaths from congenital diseases, and particularly during the first month of life. In order to further this work the health department has organized a special corps of nurses to instruct mother's in matters pertaining to home and personal hygiene, diet, etc., and all matters that will make for healthier mothers and more vigorous children and for reduction in the number of stillbirths. These nurses are assigned to a limited number of baby health stations, and the nurses in charge of the fifty-nine baby health stations throughout the city are prepared to afford similar instruction. The health department feels that the general practitioners of the city should avail themselves of this service to a greater extent than heretofore, and their cooperation is requested to the end that they notify a baby health station nurse of those cases which they believe would be materially benefited by prenatal instruction, so that the nurse may visit and instruct her.

OHIO

Hoover Back in Cleveland.—Major Charles F. Hoover of the Lakeside Hospital Unit, who has recently returned from the western war front, spoke on "The Medical Aspects of the War" before the Academy of Medicine of Cleveland, October 19.

Million for Convalescent Hospital.—The health commissioner of Cleveland has asked that the voters pass on the consideration of the use of the entire apportionment of the million-dollar hospital bond fund for the use of the new convalescent hospital at Warrensville. This, he claims, will relieve the congestion at the City Hospital and at other Cleveland hospitals, and, furthermore, will enable Cleveland to care for wounded soldiers.

Personal.—An explosion, believed to have been caused by gas, wrecked the house of Dr. Leo F. Towers, Toledo, October 19.——Dr. Rush R. Richison, Yellow Springs, has been appointed superintendent of the district tuberculosis hospital, Springfield, succeeding Dr. Henry Baldwin. The appointment will become effective, Jan. 3, 1918.——Dr. Robert C. Longfellow, Toledo, chairman of the Elk's Food Conservation Bureau, who offered his service and that of the Toledo Clinical Laboratories for government use, has been appointed a member of the county committee by the state food administrator.

District Association Meetings.—The annual meeting of the Ninth District Medical Association was held in Portsmouth, October 4. Ironton was selected as the next place of meeting. Dr. W. Wilson Lynd, Ironton, was elected president, and Dr. Ephraim E. Ellsworth, Ironton, secretary.——The Tenth District Medical Association, at its annual meeting in Mount Vernon, October 2, elected Dr. Charles D. Mills, Marysville, president; Drs. Howard E. Jones, Circleville; Charles E. Trimble, Crestline; Oscar W. Bonner, Delaware; Herbert M. Platter, Columbus; Francis W. Blake, Gambier; Amos F. Green, West Jefferson; George H. Pugh, Mount Gilead; Raymond E. Bower, Chillicothe; Argus B. Swisher, Marysville, and Blenn R. Bales, Circleville, vice presidents, and Dr. George W. Keil, Columbus, secretary-treasurer.——The Second Counsellor District Medical Association held its annual meeting and postgraduate clinic course at Dayton, September 24 to 28, under the presidency of Dr. Leora G. Bowers, Dayton. Clinics were held from 9 to 4 on each day of the session, and the following officers were elected, September 27: president, Dr. Edwin M. Huston, Dayton; secretary, Dr. Edgar L. Braunlin, and treasurer, Dr. Herbert C. Haning, all of Dayton. ——The Eighth Counsellor District Medical Society, at its meeting in Zanesville, September 20, elected Dr. John G. McDougal, New Lexington, president, and Dr. Robert W. Miller, Hemlock, secretary-treasurer. New Lexington was selected the place of meeting for next year.

Cincinnati

Personal.—Dr. Harry Freudenberger has been granted a permit in the Probate Court to change his name to Philip Gath.——Dr. Allen W. Freeman assumed his duties as state health commissioner, October 1.——Dr. John M. Withrow has made a plea in behalf of the newly created State Board of Education for funds for the overhead expenses of the board, in applying the Smith-Hughes Vocational Education Tax.

OKLAHOMA

Personal.—At its October meeting, the Board of Medical Examiners of Oklahoma elected as secretary, Dr. James J. Williams of Weatherford, in place of Dr. Ralph V. Smith, Tulsa, who resigned and joined the Medical Reserve Corps.

Antituberculosis Work.—The Oklahoma Association for the Study and Prevention of Tuberculosis has selected Jewell Schevitz, who has been director of the Sanitary Survey of Union Hill, N. J., as secretary of the association, with a special duty of organizing the state for permanent antituberculosis work. Mr. Schevitz has already opened office in Oklahoma City.

PENNSYLVANIA

Glanders Epidemic.—Glanders is reported to be epidemic in Pittsburgh, where in the three weeks preceding October 11, thirty horses afflicted with the disease were shot. Watering troughs throughout the city have been ordered closed.

Cumberland Valley Physicians Meet.—At the fifteenth annual meeting of the Cumberland Valley Medical Association, held in Boiling Springs, the following officers were elected: president, Dr. Percy D. Hoover, Waynesboro; vice presidents, Drs. William C. Schultz, Waynesboro, and Henry C. Lawton, Camp Hill; secretary, Dr. John J. Coffman, Scotland (reelected), and treasurer, Dr. John C. Gilland, Greencastle.

Personal.—Dr. Samuel G. Dixon, state health commissioner, who has been under treatment in the University Hospital, Philadelphia, on account of a nervous breakdown, is reported to be improving.——Dr. Harvey L. Gerberich, Lebanon, who was operated on for strangulated hernia in the Good Samaritan Hospital, October 14, is reported to be making satisfactory progress toward recovery.——Dr. William M. Lynch, Clark's Summit, has been reelected superintendent of the Fairview Hospital for the Criminal Insane.——Dr. Adolph Koenig, Pittsburgh, has been reappointed a member of the State Bureau of Medical Directors and Licensure.——Dr. Howard W. Gibbs, Scranton, has been made surgeon in chief of the Northern General Hospital, Sheffield, England.——Dr. John B. McAlister, Harrisburg, has been appointed a member of the commission to study health insurance.

Hospital Course for War Nurses.—October 25, hospitals throughout the state were asked by the state committe of public safety to provide a special three-month training course for nurses in an effort to meet the shortage caused by the war. The appeal was made by the department of the committee devoted to the work of sanitation and medicine, and was sent to each of the principal hospitals. In urging the adoption of the plan, the appeal says:

> "Such a course is offered at the University of Pennsylvania Hospital to women who do not care to enter for three years' training to become graduate nurses. Women between the ages of 21 and 42 who have completed Red Cross work in hygiene and home care of the sick are admitted to this course. They are required to spend a probationary period of two weeks in the hospital, furnish health certificates and personal references before being accepted for the three-months' work. Their work includes practical training, bed-making, serving food, caring for wards, waiting on patients in minor capacities with full opportunity being given for observing all details of hospital work.

Philadelphia

Contract Let.—The Department of Health and Charities has awarded the contract for the power plant for the Philadelphia General Hospital.

Personal.—Drs. Samuel Wolf and Rae S. Dorsett have been appointed members of the staff of the Philadelphia General Hospital.——Dr. Frank C. Hammond has succeeded Dr. Alexander C. Abbott on the board of health. Dr. Abbott has entered the federal service.

Tree as Memorial to Dr. James William White.—A red oak tree was planted in Rittenhouse Square, October 26, in memory of the late Dr. James William White, noted surgeon and author. The ceremony, arranged by the Walnut Street Business Association, was the feature of fall Arbor Day observances in this city. Edgar Fahs Smith, provost of the

University of Pennsylvania, and Dr. Wilmer Krusen, director of public health and charities, spoke at the Rittenhouse Square celebration. Eli K. Price accepted the tree on behalf of the park commission.

Recommendations Regarding Venereal Diseases.—The following recommendations adopted by the Committee on Health and Sanitation of the Philadelphia District Committee of the Pennsylvania State Committee of Public Safety have been made to the director of the Department of Health and Charities of the City of Philadelphia:

1. That for the best interests of the city, and the sailors and soldiers within its borders, prostitutes, when diseased, be isolated, efficiently treated medically, and quarantined in properly equipped hospitals until their infectious stage has subsided.

2. That a squad of women policemen be created to control street walkers.

3. Realizing the appalling fact that 90 per cent. of dispensary patients afflicted with venereal diseases quit treatment before discharged cured, it is desirable to use coercion through the cooperation of civil and medical authorities, of these moral slackers, if the indiscriminate spread of venereal disease is to be controlled. It is highly important before undertaking such action to abolish the medical imposters infesting communities, whose sole object is to lure and rob ignorant young men; therefore, the Board of Health is urged to adopt and enforce regulations which shall abolish so-called "medical museums" and advertising "specialists" and quacks. Also,

4. That the Department of Health have notices relative to the diagnosis and treatment of venereal disease prepared, stating the names of hospitals fulfilling the standard requirements, their location, dispensary and admission hours; that these notices be framed and placed in all public lavatories, saloons, theaters, hotels, industrial plants, department stores, military bases and cantonments.

5. That the venereal wards of the Philadelphia Hospital have their bed capacity increased so that that institution may properly care for infected prostitutes and misdemeanants referred from the Municipal Court and other sources.

Recommendations made to the State Board of Medical Education and Licensure:

1. That all general hospitals receiving or hoping to receive State aid financially shall maintain a separate Department of Genito-Urinary Surgery and Venereal Diseases with a recognized Staff position distinct from the Department of General Surgery.

2. That this Department shall consist of both an Out-Patient and Ward Service, prepared to receive patients afflicted with acute contagious and transmissible venereal diseases, who at the discretion of the Chief of the Genito-Urinary Department should be admitted.

3. That such hospitals be provided with the proper laboratory equipment for microscopical, bacteriological, serological or other examination and treatment of patients.

4. That in all hospitals maintaining a Department of Venereal Diseases it is advisable for the Social Service Department to provide male as well as female representatives for cooperation in tracing and controlling moral slackers afflicted with venereal disease.

VIRGINIA

Hospital Association Incorporated.—The Prince George Hospital Association has been incorporated at Hopewell with a capital of $50,000. Dr. Johannes C. Bodow, Hopewell, is president of the association, and C. F. Cockey, secretary-treasurer.

Richmond Districted.—In order to promote efficiency of inspection. Dr. Roy K. Flannagan, chief health officer of the city, has divided the city into eight districts, with an inspector for each district. These inspectors will be under the general supervision of Chief Inspector Walter Lowry.

Personal.—Drs. Stuart McGuire, Richmond, and Thomas C. Firebaugh, Harrisburg, have resigned from the state board of health on account of entering military service. Harry T. Marshall, Charlottesville, has been appointed a member of the board to succeed Dr. Firebaugh.——Dr. C. Curtis Hudson, Danville, has been elected full-time health officer of Charlotte, N. C.——Dr. Edward T. Glover has succeeded Dr. Gray G. Holladay, Portsmouth, resigned, as coroner of Norfolk.

New Officers.—At the annual meeting of the James City County Medical Society, held in Williamsburg, the following officers were elected: president, Dr. John M. Henderson, mayor of Williamsburg; vice president, Dr. Albert M. Sneed, Toano, and secretary-treasurer, Dr. David J. King, Williamsburg. A resolution was adopted providing that each member agree to contribute $50 a year toward the fund to be paid monthly to the wife and dependents of any member of the society who may be called into service of the country.

CANADA

Hospital News.—Mr. Horace L. Brittain of the Municipal Research Department, Toronto, has been appointed superintendent of the Toronto General Hospital for one year, Dr. Charles K. Clarke, who resigned over a year ago, continuing as medical superintendent. The Toronto General Hospital has been running behind at the rate of $4,000 a month, and has recently asked the city council for a grant of $50,000. In fact, all the hospitals have been hard pressed, as they are all seeking grants from the city treasury.

New Ontario Laboratories Opened.—October 25, the formal opening exercises of the new laboratories of the Ontario Board of Health were conducted by the Duke of Devonshire. The laboratories are about 8 miles from Toronto, and are the gifts to the University of Toronto of Col. Albert Goodesbane, and represent an expenditure of $75,000. The director is Major J. G. Fitzgerald. They are named the Connaught Laboratories, after the former Governor-General of Canada, and are the only serum laboratories in Canada. Besides preparing tetanus serum for overseas, the laboratories also prepare, both for war and local purposes, meningitis and pneumonia serum, diphtheria antitoxin, typhoid vaccine and the Pasteur treatment.

Personal.—The Canadian Associated Press reports that Gen. Guy Carleton Jones, C. M. G., Ottawa, Ont., is returning to Canada to resume his duties as Director-General, Army Medical Services, which have lately been discharged by Gen. John Taylor Fotheringham, C. M. G.——Dr. Wilmer Denny, who was graduated from the Western University, London, Ont., a few months ago, has been commissioned medical officer in the Royal Navy.——Lieut. W. S. Smith, R. A. M. C., Kingston, Ont., who has served in France and Saloniki, was home for a short time with rheumatism, but has joined the C. A. M. C., and has returned to England.——Major Henry E. Paul, Fort William, Ont., is in command of the Canadian hospital at Etchinghill, England. On the staff are Capts. Henry K. Bates, Toronto; George O. Scott, Ottawa; Allan M. Yates, London, Ont.; John G. Gunn, Ailsa Craig, Ont.; William T. Lockhart, Carnduff, Sask,; Burpee F. Steeves, Claresholm, Alta.; A. B. Jackson, Simcoe, Ont., and Lieut. A. V. Greaves, Toronto.

Dr. Simon Flexner in Toronto.—October 25, Dr. Simon Flexner of the Rockefeller Institute, New York, addressed a large audience of medical men and students in Convocation Hall, University of Toronto. The subject was "Certain War Activities of the Institute." Dr. Alexis Carrel, New York, had been in France since the beginning of the war, and one of the first of the war activities was to deal with the alarming and frequent occurrence of gaseous gangrenes, and even yet no adequate preventive measures had been evolved. From the time of the discovery of the micro-organism responsible for the disease until 1914, only 200 cases had come to light. It became common in France in a very short time, induced largely by the richly fertilized soil. The bacilli clung even to sterilized uniforms. He told of the opening of a small hospital for experimental purposes, and of the use of chlorin and boric acid to eliminate the bacilli from the system. Finally, an antitoxin was compounded which, it was hoped, would dominate the gaseous gangrene curse. He also spoke of the tetanus antitoxin, and looked for much preventive and curative benefit therefrom. Pictures were shown of the experimental hospital.

GENERAL

Southern Physicians to Meet.—The Southern Medical Association will hold its annual meeting in Memphis, Tenn., November 12-15, under the presidency of Dr. Duncan Eve, Sr., Nashville.

Railway Surgeons to Meet.—The New York and New England Association of Railway Surgeons will hold its twenty-seventh annual session at the Hotel McAlpin, New York, November 8, under the presidency of Dr. Halbert G. Stetson, Greenfield, Mass.

The Waring Case.—House Bill No. 6343 has been brought before Congress by Mr. Montague, and authorizes the President to nominate, and with the advice and consent of the Senate, to appoint John B. Waring, late a captain in the Medical Corps on the retired list, increasing the list by one, for this purpose.

New Electrotherapeutic Officers.—The American Association of Electrotherapeutics and Radiology, formerly the American Electrotherapeutic Association, at its annual meeting elected the following officers: president, Dr. Frank B. Granger, Boston; secretary-registrar, Dr. Byron S. Price, New York, and treasurer, Dr. Emil Heuel, New York.

Foundation of Urology.—Under an agreement between the executors of the estate of the late James Buchanan Brady and his heirs, most of the estate, estimated at $3,000,000, is now available for the New York Hospital, and makes possible the establishment of the James Buchanan Brady Foundation of Urology, which is in accordance with the testator's plans. Dr. Oswald S. Lowsley, who was named by Mr. Brady as director, has the plans of the foundation in charge.

New Officers for Public Health Association.—At the forty-fifth annual meeting of the American Public Health Association, held in Washington, D. C., October 17-20, under the presidency of Dr. William A. Evans, Chicago, the following officers were elected: president, Dr. C. O. Hastings, Toronto, Ont.; vice presidents, Drs. George M. Kober, Washington, D. C.; Emanuel S. Iglesias, Vera Cruz, Mexico, and Guilford H. Sumner, Des Moines, Iowa; secretary, A. W. Hedrich, Boston, and treasurer, Lee K. Frankel, New York. The association adopted the resolution favoring the bestowal of the Nobel Price on Major-Gen. William C. Gorgas, Surgeon-General, U. S. Army, for placing yellow fever in the list of preventable diseases.

Georgia Board Investigates Charges.—The Georgia Board of Medical Examiners recently heard charges preferred against Dr. J. A. McLeay, Atlanta, to the effect that, under the charter of the Southern College of Medicine and Surgery of Atlanta, which was closed in 1914, he had been illegally issuing medical diplomas for a stipulated sum. The matter was referred to the solicitor general of the superior court for action. The board also heard charges of using forged licenses against Drs. C. J. Malloy, Helena; S. B. Ellis, Whilesburg; F. C. Bentley, Crandall, and W. R. Rothrock, Athens. There is no record of licenses having been issued to these physicians. The board directed the secretary to assist the county solicitors in prosecuting these men on charges of illegally practicing medicine.

Foreign Patents to Be Open to American Manufacturers.—Since the outbreak of the war there has been a shortage of certain synthetic drugs, especially salvarsan and neosalvarsan. As the patents for many of these drugs were owned by German firms, American manufacturers, of course, could not make them. When the United States severed its relations with Germany, it was realized that some provision should be made to supply articles controlled by enemy-owned patents. As early as June, Congress was considering "the trading with the enemy act," then known as "The Adamson Bill," the purpose of which was to confer authority on the President to license American firms to use German patents. In the latter part of September, the "trading with the enemy act" finally became a law.

During this period, Dr. Marston T. Bogert, chairman of the Committee on Chemistry of the National Research Council, was being aided by a special committee on synthetics composed of Julius Stieglitz, chairman, president of the American Chemical Society; Roger Adams of the University of Illinois, M. Gomberg of the University of Michigan and W. A. Puckner, secretary of the Council on Pharmacy and Chemistry. (Shortage of Synthetic Drugs, The Journal, Aug. 4, 1917, p. 400.) This committee gathered information as to drugs which were difficult to obtain, and considered recommendations which might be made for the enforcement of the law. On October 30, the Federal Trade Commission held a conference in Washington regarding the granting of licenses of enemy patents, at which the material of this and other committees was placed at the disposal of the Trade Commission. According to reports at hand, the discussion covered questions of manufacture, of control of the product, distribution and price.

The regulations issued by the commission based on the law safeguard the interests of patent owners, who, after the war, are to receive some remuneration for the use of their inventions, and provides that licenses will be issued only where the public welfare demands it—that is, to supply a demand not now being met. In this connection it is well to point out that the number of drugs of which there is a serious shortage is not great. Even in Great Britian—which has a law similar to the trading with the enemy act—relatively few German patents have been turned over to English licensees.

FOREIGN

Argentine Medical Bibliography.—Under the auspices of the *Revista Medica del Rosario,* the classified medical bibliography for Argentina during the year 1916 has been published in a 120-page pamphlet. The compilation was done by Dr. M. A. Blanco.

Serum and Vaccine Institute at Naples.—Prof. I. Bandi has been placed in charge of the newly opened institution at Naples for production of therapeutic serums and vaccines and as a center for research in hygiene and biology, with special regard to colonial conditions.

The Argentine Medical Association.—A recent three-day meeting at Buenos Aires of this association was devoted to brain tumors. The differential diagnosis was presented by Drs. Castex, Alurralde, Borda, Chiappori and Houssay, the operative treatment by Segura, Palma and Finochietto, while D. J. Cranwell spoke on echinococcus disease of the brain.

Deaths in the Profession Abroad.—**E. Delens,** *agrégé* professor of ophthalmology at the University of Paris until retirement, aged 78.——**A. J. F. Dastre,** chief of the laboratory for animal physiology at the University of Paris, killed in an automobile accident. From recent casualty lists, British: Surg. **A. E. Panter,** Capt. **W. R. Aspinall** (Australian), Lieut. **J. F. Elliott,** Asst. Surg. **A. R. Underwood,** Lieut. **R. F. Hiley,** Capt. **F. Hardie,** Capt. **R. L. Henderson** (Australian). Italian: Lieut. **G. Maccia;** Capt. **E. Boeri,** Lieut. **G. Polcher,** Lieut. **S. Redaelli,** Capt. **G. Castornio,** Capt. **C. T. Aurelio,** Lieut. **B. Gallotti.**

Medical Supplies in India.—Madras is the center for government medical supplies in India. Since the outbreak of the war, the manufacture and preparation of drugs has been centered in that city. Until 1912, Calcutta had been the manufacturing place, but it has been converted into a distributing center, as has been the case also with Rangoon. At Bombay certain stores have been specializing in the manufacure of surgical instruments. It is expected by the director of stores in Madras to make disinfectants, especially those of the phenol group, emetin, and starch from rice. Castor oil is manufactured and the possibilities of making glycerin are being investigated. It is proposed also, according to *Commerce Reports,* to increase the production of field dressings, bandages, etc. Quinin is now manufactured at Nilgiris and the Indian government medical service at Simla has completed inquiries regarding the increased cultivation of cinchona in Bombay, Madras, Burma and other provinces.

Shortage of Physicians in Great Britain.—Comment in the *British Medical Journal* (Sept. 29, 1917, p. 428), shows that for the next few years the annual output of physicians from the British medical schools will fall below the normal annual decrease in times of peace. The shortage of physicians will be even more marked hereafter owing to the pressing demands of the army service and the casualties resulting in that service. The normal annual decrease in the number of physicians is placed at 900. Figures collected recently show that only 900 men each year are due to qualify in 1917 and 1918. The shortage will be still more serious in 1919, 1920 and 1921 when, respectively, only 519, 800 and 700 physicians are due to qualify. It is said that the supply of physicians for the need of the civil population has already been reduced to the minimum consistent with safety. All the new additions to the ranks of the medical profession are to be at once requisitioned for army medical service so that there will be no reserves to make up the annual depletion from deaths and retirement from practice. The outlook both for civil and army medical services in Britain, therefore, is quite unsatisfactory. Even the demobilizing of medical students now in the ranks so they can return to the medical schools and complete their training, a measure now being planned, will fall considerably short of meeting the requirement.

PARIS LETTER

Paris, Sept. 13, 1917.

The War

AUTOCHTHONOUS MALARIA

Drs. Victor Raymond and Grysez have communicated to the Réunion médico-chirurgicale de la III-e Armée their observations of four patients who entered the hospital presenting the following symptoms: fever of short duration, the temperature falling to normal subsequently, with febrile paroxysms recurring from day to day, without definite periodicity, and of several hours' duration. In the interval there was a slight degree of anemia without any gastro-intestinal disturbance, no pain in the tibias, but always a very marked hypertrophy of the spleen. The symptoms would at first lead one to think of malaria, but none of the four patients seen had ever been outside of France, nor did they ever have any intermittent fever; they came from nonmalarial districts, two from Paris, one from the department of Basses-Pyrénées and one from the department of the Marne. In three of these cases the blood was examined at the beginning of the febrile attack. In all three a hematozoon was found. This parasite was that of benign tertian fever, *Plasmodium vivax:* gregariniform, with rosettes having sixteen nuclei, oval gametes, Schüffner's grains; no crescents. The affection is benign, and the febrile paroxysm may be suppressed by means of quinin, given by mouth, in doses of from 1.5 to 2 gm. for three successive days. Inquiry established the fact that the disease originated in one corps which had been stationed for many weeks in an inundated district abounding in mosquitoes. The members of this corps had all been stung many times by these insects. The examination of a certain number of mosquitoes gathered from that region showed that 7 per cent. were *Anopheles.* The corps in which these cases occurred had been preceded in that section by a native regiment, and some weeks previously it had received an increment of some size consisting of repatriates from Saloniki, many of whom presented relapses of malaria. It is a question, therefore, whether this is not to be regarded as a small focus of autochthonous malaria, because the region in which these cases appeared was free from malaria before the war. It is better, perhaps, to assume that the repatriates from Saloniki played the rôle of virus reservoirs or carriers. Dr. Abrami has stated that benign tertian malaria and its parasite, the *Plasmodium vivax*, have occurred frequently at Saloniki this year, and that the small percentage of *Anopheles* explains the small number of cases observed.

NO FURTHER EXEMPTION FOR PHYSICIANS ON THE GROUND OF PHYSICAL UNFITNESS

The undersecretary of state of the Service de Santé militaire has made known, by means of a circular, that there is to be no further exemption of medical men on the basis of physical unfitness. Hereafter, every doctor who is called into service will be utilized as far as his physical unfitness will permit.

PRACTICE OF CIVIL MEDICINE BY THE MOBILIZED PROFESSION

M. Chassaing, having demanded of the ministry of war (1) whether in the zones of the armies the physicians of a unit stationed in a locality unprovided with civil physicians are obliged to give their services to the civil population, or whether they may choose to do so; (2) whether they must visit the civilian sick in localities other than the one in which their cantonment is situated; (3) if they have the right to ask for transportation to patients residing at some distance, and if, in the course of such transport, there occurs an accident, will the case be considered as having occurred in the line of duty; (4) if they have the right to demand or expect an honorarium, received the following reply:

"The regulation relative to placing the army medical man at the disposal of communities unprovided with physicians not mobilized is applicable in the army zones as in the interior. The army physicians so detached ought to be called from the personnel of the region and not from any sanitary formations on duty in that region. However, the surgeons in chief of such sanitary formations may place their personnel at the disposal of civilians who are without medical service in the absence of physicians detached by the directors of this region. Under the circumstances, it is well to understand that service is assured by the medical personnel of the army under the same conditions as by the personnel of the region, that is to say, gratuitously, and if necessary, means of transportation are to be placed at their disposal by the municipal authorities. In the case of accidents occurring in the course of this detail or absence on such service, these medical officers are considered as being in actual service."

CREATION OF A COMMITTEE ON CHEMICAL PRODUCTS

The minister of commerce has appointed a committee to investigate the sale and manufacture of chemical products, coloring agents, pharmaceutical products, photographic materials, perfumes, etc. This committee is charged to determine, centralize, coordinate or control the needs of the state and of the public; to provide means to meet, in the best manner possible, the needs of the nation; to secure rational utilization of the resources of the country; to satisfy the demands of home as well as of foreign trade; the sale and transport and manufacture, the importation, the exportation and the composition of stock. So far as concerns the industries utilizing reserve materials, particularly for national defense, the committee has fixed and proposed to the proper ministry: the monthly allotment of materials placed at the disposition of private industries; the prices of materials and products given up by the state, and the prices and the conditions of sale and consumption of products manufactured by the private industries from materials and products given up by the state.

WINE RATION OF THE SOLDIERS

The minister of food control (ravitaillement), in accord with the ministry of war, has decided to increase the soldiers' daily wine ration to 0.75 liter. This had previously been fixed at 0.5 liter. The measure becomes effective, Jan. 1, 1918.

A Home for American Students in Paris

The municipal council of Paris has offered to the universities of the United States ground on which to construct a home for American students. This territory is about 1,000 meters square, and is situated on the Champ-de-Mars. Building operations will be begun shortly, thanks to the efforts of Mr. James Hyde, originator of the idea of this foundation; to Prof. Barrett Wendel, president, and to Mr. Bliss, secretary of the committee resident in New York, which will raise the necessary funds by subscription. The committee has already received a number of gifts. Ere long, the American students who, year after year, come to France in rather large numbers, will have in Paris a large establishment, appointed in the most modern style, where they will be entirely at home.

Death of Dr. Jouty

Dr. A. Jouty, otolaryngologist of the municipal hospital of Oran, died at Lyons from fulminant septicemia, the result of an accidental infection. He has been in continuous service since the beginning of the war, first at Oran, then at Bel-Abbès, and finally at Lyons, where he had charge of a special service.

LONDON LETTER

London, Oct. 8, 1917.

The War

THE AIR RAIDS

During the harvest moon, London has endured an unprecedented succession of air raids—six in eight days. They commenced soon after sunset and lasted from one to three hours. The enormous development of the defenses enabled a heavy barrage fire, appalling to witness, to be maintained almost continuously for as long as an hour when necessary. The roar of the guns was so continuous as to suggest the working of some gigantic machinery. Thanks to the effectiveness of the barrage, only one or two of the raiders, whose number on each occasion is estimated at about twenty machines, got through. The casualties were therefore few. Ample provision had been made to deal with them by organizing ambulance parties in every district of the metropolis. The danger to those in the open air was really greater from our own shrapnel, which in some districts dropped like rain. But on receiving the warning of the approach of the raiders, the public quickly took cover in the basements of houses, or in buildings that offered special protection. The underground tube stations were ideal places of refuge and were crowded, principally by foreigners. The mental effect produced on the majority of the English people was very different from that calculated on by the Hun, with his usual ignorance of the psychology of other races. Of terror or panic there was very little, and this was almost confined to women anxious about their children. The predominant feeling was intense anger that German cities were not subjected to the same experience. Indeed, this feeling has at last forced the government to announce that German cities will be raided. Unlike our barbarous foes, we shall as far as possible spare women and children by attacking munition works and other military objectives.

AN AMERICAN HOSPITAL OPENED IN LONDON

Dr. Page, United States Ambassador, has opened St. Catherine's Lodge, Regents Park, as a hospital for American and British officers. The house with grounds of about 4 acres has been equipped for forty patients by Mr. and Mrs. William Salomon of New York, owners of the lease, who will maintain it for the duration of the war. It is controlled by the London chapter of the American Red Cross, and is the first American Red Cross Hospital established in Europe. It is fitted to accommodate orthopedic patients. Two of the American orthopedic surgeons who came to this country under the command of Major Goldthwait of Boston, and are attached to the Sheperd's Bush Military Orthopaedic Hospital, Capt. E. Kidner of Detroit and Capt. de Forrest Willard of Philadelphia, have been chosen as the nucleus of the medical unit under the supervision of Col. Sir Robert Jones. The nursing staff will be American. For work other than orthopedic, some of the most eminent London physicians and surgeons have offered their services. Dr. Page said he had to acknowledge the great generosity of the donors. It was gratifying to find the work of the American Red Cross well started in London. The hospital differed from others in that it would give orthopedic treatment to officers. He was told that 70 per cent. of cases yielded to the treatment which had been developed under the leadership of Sir Robert Jones.

AUSTRALIAN PHYSICIANS DECIDE FOR CONSCRIPTION

The members of the British Medical Association in Australia have replied to the question whether they desire conscription of the medical profession in Australia for service at home and abroad. Out of a total of 1,361 votes, 1,011 were given in favor of conscription—a majority of practically 75 per cent. The voluntary system has achieved great results, but they are not now adequate to the requirements of the army. Under it nearly 1,000 physicians out of a total well under 3,000 relinquished their practices and proceeded overseas with the expeditionary force. In addition, 400 undertook military service in the commonwealth. Of those that went to the front, the number who have given their lives amounts to fifty, a proportion greater than that of the combatant troops.

The Health of Schoolchildren

Sir George Newman, chief medical officer of the board of education, has published his annual report for 1916. He states that the fact must be faced that in 1916, as in former years, the records show a large amount of ill health and physical and mental defect. A year ago a moderate computation yielded not less than a million children of school age as being so defective or diseased as to be unable to derive reasonable benefit from education. What is needed is an effective unification of all the powers having for their purpose the healthy upbringing of youth. In addition, it is essential that the local education authorities should have continually before them a clear view of the steps necessary to secure the full value of the school medical service to every child of school age in their area. He considers that the irreducible minimum that will yield the results the nation requires is as follows: 1. Every child shall periodically come under direct medical and dental supervision, and if found defective shall be "followed up." 2. Every child found malnourished shall, somehow or other, be nourished; and every child found verminous shall, somehow or other, be cleansed. 3. For every sick, diseased or defective child skilled medical treatment shall be available, either by the local education authority or otherwise. 4. Every child shall be educated in a well ventilated schoolroom or classroom, or in some form of open-air schoolroom or classroom. 5. Every child shall have daily organized physical exercise of appropriate character. 6. No child of school age shall be employed for profit except under approved conditions. 7. The school environment and the means of education shall be such as can in no case exert unfavorable or injurious influence on the health, growth and development of the child. Dealing with the care and training of children under the school age, that is, under 5, the report states that their physical and mental well-being is not adequately provided for. The view is expressed that eventually it may be thought desirable that they should be educated on the lines suggested by the Consultative Committees for Nursery Schools.

The importance of dental disease is becoming more evident to the educational and military authorities concerned. So widespread is oral sepsis, and ill health directly due to the bad condition of the teeth, that great national efforts must be made to deal with the problem. The school is the place, and childhood is the time to intervene. A chapter is devoted to the benefits that are derived from an open-air life. It is estimated that there are not fewer than 600,000 children for whom the best possible treatment is an open-air school, and the need for the extension by authorities of their present facilities for open-air education is stated to be urgent.

The teaching of mothercraft is also dealt with. It is laid down that if the schoolgirls of this generation are to become wise mothers of the next, they must be taught the elements of mothercraft. The teaching of mothercraft may be divided into three periods: (1) instruction to the older girls at the elementary schools; (2) instruction to girls from 14 to 18 years old, and (3) instruction to married women. Where introduced, the teaching of mothercraft is declared to be satisfactory and practical; but the schools in which it is in operation are far too few; and apart from isolated lessons given during training in housewifery, etc., local education authorities have done almost nothing to encourage the general introduction of this teaching throughout all schools in their areas.

In regard to physical education, Sir George Newman remarks that there is an increasing recognition of its value. The problem before the board of education has heretofore been relatively narrow, namely, to lay the foundations of a system of physical training throughout public elementary schools and encourage its development in secondary and continuation schools. Now their field of action is likely to be enlarged. The work hitherto accomplished must be strengthened and established, and if, as is hoped, all children remain at school till at least 14, the teaching of physical exercises in the public elementary school can be expanded and more satisfactorily carried out than when any children leave at the age of 12 or 13.

The control of juvenile employment is considered in all its aspects. Through the history of child labor, the dominant evil is not accidents, or poisoning, or deformities, or specific disease, but the stress and fatigue of the immature body due to long and unsuitable hours of occupation. The only remedies are that (*a*) no child under 14 shall be exempted from education, half-time, or whole-time, for purposes of employment for profit; (*b*) no child attending school shall be employed out of school hours except at prescribed hours and for prescribed periods, and (*c*) the employment of all young persons from 14 to 18 should come under the medical supervision and control.

Marriages

Lieut. Charles Hyatte Cherry, M. R. C., U. S. Army, Fort Riley, Kan., formerly of Chisholm, Minn., to Miss Rebecca O. Jacobs of Topeka, Kan., recently.

Lieut. William Lytle Ross, Jr., M. R. C., U. S. Army, Garden City, Long Island, N. Y., to Miss Ethel Jeanette Nixon of New York City, October 6.

Lieut. John Andrews Rogers, M. R. C., U. S. Army, Nashua, N. H., to Miss Edith Pearl Batchelder of Framingham, Mass., September 8.

Paul Emerson Gilmor, M.D., a medical missionary in the Egyptian Sudan, to Miss Esther Margaret McCracken of Pittsburgh, September 5.

Lieut. Edward Foulke Corson, M. R. C., U. S. Army, to Miss Esther Bisler, both of Philadelphia, in Chicago, October 15.

Lieut. Dana Byron Dishmaker, M. R. C., U. S. Army, to Miss Olga Bertha Haney, both of Kewaunee, Wis., October 20.

Lieut. Fay J. Ernest, M. R. C., U. S. Army, Topeka, Kan., to Miss Edith Knox of Topeka, in Kansas City, July 23.

Frederick Yates, M.D., Washington, D. C., to Mrs. Mary Estelle Archer of Chevy Chase, Md., September 20.

William Armitage Moncrieff, M.D., to Miss Beryl Stuart Smith, both of New Bedford, Mass., September 29.

Asst. Surg. Matthew F. Czubak, U. S. Navy, to Miss Rhoda Evans Gilles of Philadelphia, August 30.

Joseph Raoul Larochelle, M.D., to Miss Jeannette R. Roussin, both of Biddeford, Me., October 8.

John A. Ragone, M.D., Buffalo, N. Y., to Miss Margherita Agnes Tirendelli of Cincinnati, October 3.

Susan Anderson, M.D., Fraser, Colo., to Mr. George Schaus, at Prescott, Iowa, October 10.

Amos John Winkel, M.D., to Miss Helen Leigh Hunt, both of Hamburg, N. Y., October 13.

David Thomas Heyser, M.D., Emad, La., to Miss Ola Manning of Kinder, La., October 3.

Philip B. Newcomb, M.D., Bangor, Me., to Miss Dorothy Williford in New York, October 1.

Thomas H. Gilland, M.D., Greencastle, Pa., to Miss Daisy B. Daley of Baltimore, October 17.

George Milbry Gould, M.D., to Miss Laura Stedman, both of Atlantic City, N. J., October 3.

Herman Lucas Earl, M.D., Jewell, Ga., to Miss Ella Berry of Sparta, Ga., October 9.

Clark Jay Stevens, M.D., Rockville, Ind., to Miss Roxie Parker, at Chicago, October 17.

Russell J. Murdoch, M.D., to Miss Ruth M. Palmer, both of Blair, Neb., October 3.

George Alfred Felch, M.D., to Miss Janey E. Little, both of Boston, October 4.

Deaths

Richard Halsted Ward, M.D., Troy, N. Y.; College of Physicians and Surgeons in the City of New York, 1862; aged 80; a Fellow of the American Medical Association and American Academy of Medicine; a member of the Royal and Belgian microscopical societies; acting assistant surgeon in the Army during the Civil War; instructor in botany in 1867, and lecturer and professor in histology and microscopy in the Rensselaer Polytechnic Institute, Troy, from 1869 to 1872; governor and first vice president and chairman of the medical board of the Marshall Infirmary and Sanitarium since 1868; notable as a research worker in economic botany and microscopy and as an expert in microscopy; an honorary member of many foreign societies; died at his home, October 29.

LeGrand Atwood, M.D., Ferguson, Mo.; Washington University, St. Louis, 1849; aged 85; a member of the Missouri State Medical Association, and a life member of the St. Louis Medical Society, and president in 1885; surgeon in the Confederate Service during the Civil War; superintendent of the St. Louis Insane Hospital from 1886 to 1891, and of State Hospital for the Insane, No. 1, Fulton, in 1891 and 1892; lecturer on therapeutics and toxicology in St. Louis Medical College, and lecturer on nervous diseases in the Marion-Sims Hospital College, St. Louis; died at his home, August 2.

Robert Watts, M.D., New York; College of Physicians and Surgeons of the City of New York, 1861; aged 80; a member of the Medical Society of the State of New York; surgeon of the One Hundred and Thirty-Third New York Volunteer Infantry during the Civil War; consulting gynecologist to the Roosevelt Hospital, and consulting physician to the City and St. Mary's Children's hospitals; died at his home, October 15.

Charles Forbes, M.D., Rochester, N. Y.; College of Physicians and Surgeons in the City of New York, 1871; aged 73; for many years an instructor in natural science; a research worker especially in photography and electricity; inventor of the individual communion cup, in 1894; and more recently, of a gauze bandage, drain, and sponge roller; died in the Rochester General Hospital, October 2.

J. Homer Darling, M.D., Thompsonville, Conn.; Castledon, Vt., Medical College, 1859; aged 79; assistant surgeon of the Fifty-First Massachusetts Volunteer Infantry; and Acting Assistant Surgeon, U. S. Navy, during the Civil War; once president and for several terms a member of the local school board; died at his home, October 18.

Stephen Cassin Spalding, M.D., Shenandoah, Pa.; University of Maryland, Baltimore, 1870; aged 73; formerly a member of the Medical Society of the State of Pennsylvania; a director of the Citizens' Building and Loan Association and Shenandoah Mutual Fire Insurance Company; died at his home, October 11.

John Frank Simison, M.D., Romney, Ind.; Rush Medical College, 1881; aged 58; township trustee in 1885 and 1887, and a member of the legislature in 1907 and 1909; for many years a trustee of DePauw University; died in St. Elizabeth Hospital, Lafayette, October 15, a week after an operation for appendicitis.

Herbert M. Burritt, M.D., Hilton, N. Y.; University of Buffalo, N. Y., 1901; aged 44; formerly a member of the Medical Society of the State of New York; at one time health officer of Hilton; died in the Park Avenue Hospital, Rochester, N. Y., October 11, from pneumonia complicated by diabetes.

William R. Scott, M.D., Portland, Ore.; Jefferson Medical College, 1906; aged 38; formerly a member of the Oregon State Medical Association; was found dead at his Helix ranch, October 12, from the effects of a gunshot wound of the head, believed to have been accidentally self-inflicted.

Chauncey W. Chidester, M.D., Newark Valley, N. Y.; College of Physicians and Surgeons, Chicago, 1886; aged 70; formerly a member of the Medical Society of the State of New York; for many years coroner of Tioga County; died at his home, August 16, from arteriosclerosis.

James R. Edwards, Denton, Texas (license, Texas, years of practice, act of 1907); aged 77; a practitioner for fifty-six years; formerly a member of the State Medical Association of Texas; at one time health officer of Denton County; died at his home, October 12.

Floyd S. Farnsworth, M.D., Plattsburg, N. Y., Hahnemann Medical College, Philadelphia, 1885; aged 59; a member of the Medical Society of the State of New York; died at the home of his niece in Troy, N. Y., October 12, from cerebral hemorrhage.

Amos Avery Rittenour, M.D., Denver; George Washington University, Washington, D. C., 1900; aged 42; formerly a member of the Medical Society of Virginia, and a resident of Berkeley; died in the Sarah Leigh Hospital, Norfolk, Va., October 10.

Harvey W. Scales, M.D., Yorktown, Iowa; Medical College of Ohio, Cincinnati, 1879; aged 62; formerly a Fellow of the American Medical Association; a member of the Iowa State Medical Society; was found dead in his room, October 13.

James Daniel Hewett, M.D., New York City; New York University, New York City, 1868; aged 84; assistant surgeon of the Sixty-Sixth New York Volunteer Infantry, and later major; died at his home, October 13.

Daniel W. Owens, M.D., Mosheim, Tenn.; University of Tennessee, Nashville, 1890; aged 57; formerly a member of the Tennessee State Medical Association; died at his home, July 25, from Pott's disease.

Thomas Evans Elliston, M.D., Nashville, Tenn.; Vanderbilt University, Nashville, 1880; for six years a member of the Davidson County Court; died at his home, October 17, from cerebral hemorrhage.

William Ross, M.D., New York City; New York University, New York, 1894; aged 54; formerly a member of the staff of the New York and Bellevue hospitals; died at his home, October 18.

John Myrick Crocker, M.D., Cambridge, Mass.; Harvard Medical School, 1866; aged 72; a Fellow of the American Medical Association; died at his home, October 6, from heart disease.

Henry Julius Cohen, M.D., Brooklyn, N. Y., Cornell University, 1909; aged 29; died in the Methodist Episcopal Hospital, Brooklyn, October 18, after an operation for appendicitis.

Edwin Gillard, M.D., Sandusky, Ohio; Homeopathic Hospital College, Cleveland, 1872; aged 72; once professor of gynecology in his alma mater; died at his home, October 14.

Robert Burnsides Ferree, M.D., Pittsburgh, University of Pittsburgh, 1887; aged 54; a member of the Medical Society of the State of Pennsylvania; died at his home, October 15.

Samuel Ensign, M.D., Arborville, Neb., Geneva, N. Y., Medical College; aged 98; for many years a pharmacist; died at his home, August 19, from cerebral hemorrhage.

John F. Spencer, M.D., Moore's Hill, Ind.; Eclectic Medical Institute, Cincinnati, 1869; aged 75; a veteran of the Civil War; died at his home, October 1, from heart disease.

Berzelius D. W. Thompson, M.D., Sardinia, Ohio; Cincinnati College of Medicine and Surgery, 1886; aged 79; died at his home, July 23, from carcinoma of the liver.

John B. Marchard, M.D., Monticello, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 75; died at his home, September 4, from diabetes.

J. A. Bickett, Maryville, Mo.; a practitioner since 1866; aged 79; a veteran of the Civil War; died in a hospital at Leavenworth, Kan., September 21.

Theresa G. Breene Baum, M.D., Oil City, Pa.; University of Pittsburgh, 1910; aged 38; died at her home, August 5, after an illness of two years.

William Patrick Honan, M.D., Chicago; Bennett Medical College, Chicago, 1914; aged 30; died at his home, October 25, from heart disease.

Frederick Briggs Quackenbush, M.D., Philadelphia; Hahnemann Medical College, Philadelphia, 1901; aged 50; died at his home, October 6.

Leander James Crooker, M.D., Augusta, Me.; Dartmouth Medical School, Hanover, N. H., 1871; aged 80; died at his home, October 10.

William F. Clayton, M.D., Overlea, Md.; College of Physicians and Surgeons, Baltimore, 1906; aged 35; died at his home, October 12.

Jerome P. Marvin, M.D., Harrison, Ohio; Eclectic Medical Institute, Cincinnati, 1866; aged 71; died at his home, October 12.

David M. Ray, M.D., Bernie, Mo.; University of Tennessee, Nashville, 1878; aged 71; died at his home, about September 29.

Wade Minor Logan, M.D., Cincinnati; Miami Medical College, Cincinnati, 1869; aged 69; died at his home, October 11.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

SECRECY IN PATENT MEDICINES

One Concern Proves That the "Open Formula" Does Not Spell Ruin

The Journal has long insisted that one of the greatest evils connected with the "patent medicine" business is the element of secrecy. Practically every "patent medicine" manufacturer leads the public to believe, either by direct statements or by implication, that his preparations possess some marvelous and esoteric powers—due either to a peculiar combination of well-known drugs or to the presence of some mysterious drug about which the rest of the world is ignorant—not to be found in official products or in unofficial products made by competitors. Such claims, of course, are the sheerest humbug. There is not a "patent medicine" on the market today whose place could not better be taken by some official drug or combination of drugs. So long, however, as "patent medicine" manufacturers sell names instead of drugs it is possible for them to "get away with" claims that would be laughed to scorn if the element of mystery were eliminated.

It is for this reason that the nostrum makers declare that to give to the public the names and amounts of the therapeutically active drugs in their products would spell financial ruin. In many cases it doubtless would, but not for the reason assigned by those making the claim. It would destroy business in those cases in which even the nontechnically trained layman would recognize the absurdity of claims made for simple mixtures of well-known drugs.

One of the spokesmen for the "patent medicine" interests has said:

> ". . . it is practically impossible to prove that the therapeutic claims made for a preparation whose composition is not known are 'false and fraudulent.'"

This same spokesman declared that should "patent medicine" manufacturers be forced to make their formulas public "they will be supplying evidence which may result in their own undoing."

When the public prescribes for itself it has the right to know what it is prescribing. If it cannot be given this obvious prerogative without destroying an industry, then that industry should be destroyed. The facts are, of course, that no "home remedy" having any legitimate place in commerce would be destroyed by such a course, although it would, doubtless, do much to wipe out of existence the fakes, frauds and humbugs with which the public is at present afflicted.

These facts are suggested by a letter recently received from the manager of a "patent medicine" concern. This letter so completely refutes many of the misstatements made by the exploiters of fraudulent nostrums that we print it in full. It is worth reading:

> "*To the Editor:*—Let me introduce myself, first of all, as the Treasurer and General Manager of the J. C. Ayer Company, of Lowell, Mass. I come asking the privilege of placing before your readers the marked changes that have taken place during the past few years in the methods of conducting the business of this company in every state of the Union.
>
> "Some twenty years ago I was first placed in charge of said business, although I had known of it ever since my earliest recollection. Even at this beginning I had been a physician for twenty-five years and so became at once keenly aware of the fact that certain changes could be made to the benefit of the public, and then, of course, to the benefit of the company.
>
> "While a number of changes were made at once, it was only about ten years ago that the first radical change took place, namely, when we published our full and complete formulas on all the printed matter, cartons, bottles and boxes of medicine, said change having been continued to this very day. It is interesting to know that the Canadian government ruled that because of said publication of formulas we were entirely exempt from its Patent Medicine Act.
>
> "Another change, equally important at least, was made about that same time, when we placed on the market all our medicines entirely free from alcohol. This change was made because we believed, with all our might, that alcohol is a poison too powerful and too dangerous to be used as a medicine unless under the direction of a physician. Right here let me add that there is nothing secret about this; we percolate according to standard methods, recover the alcohol by distillation, and lastly add the glycerine.
>
> "Then came the hard problem of advertising, with its constant tendency to exaggerate and thereby to mislead. A weak advertisement always reads to me like bibble-babble, while an extra strong one too often shows that the writer has been carried to dizzy and dangerous heights! So it was decided, about three years ago, to discontinue all newspaper advertising, leaving only the *Almanac* through which to make announcements to the public.
>
> "Probably it is asking altogether too much of the busy editor to read some of the more recent editions of said *Almanac*, but it is certainly true that in writing them it has ever been my earnest effort to write in a more and more conservative way, with the thought that I, as a physician, was especially bound to use my knowledge in every possible way to advance the interests of the public health. I have also endeavored to completely eliminate everything that would have a tendency to make the well man think he was sick or the sick man think he was sicker; at the same time giving a good amount of practical every-day hygiene. One result is that our 1918 *Almanac* is quite a different affair from those of my earlier efforts.
>
> "But there were other changes needed. So about two years ago we omitted all kinds of literature accompanying our medicines; no pamphlets, no leaflets, no circulars, practically no printing whatever except the formula and dose on bottle, box and carton.
>
> "Such changes naturally bring up the question of the effect on the pocketbook. I can only speak for this company, and say that we are still pursuing these same methods with increased vigor and find them more and more satisfactory. Indeed, we have never once had the slightest idea of turning back to the tallow-candle age! Some people seem to forget the brilliant period in which we are living, with its remarkable common school system, good literature, cheap postage, extensive trollies, telephones, and so on, whereby even the most remote districts in the country are brought in closest contact with the very center of our largest cities. The old-time mystery is fast disappearing as the new-time education penetrates the darkness.
>
> Charles H. Stowell, M.D., Lowell, Mass."

Dr. Stowell was graduated by the University of Michigan Medical School in 1872. In printing his letter The Journal is not to be understood as endorsing the preparations of the J. C. Ayer Company, but it does endorse the business principles shown by the company. The formulas for some of the Ayer preparations are needlessly complex and of the shotgun-mixture type; however, not more so than some of the preparations in the Pharmacopeia and National Formulary. If ever mixtures of the shotgun type are excusable, it may be when such are used as home remedies that are taken without a real diagnosis—a rifle is of little use against an obscure mark!

The important points brought out by this letter, however, are that "patent medicines" without alcohol or other habit-forming drugs can be advertised with comparative conservatism and the public given detailed information regarding their composition and the company marketing them still flourish.

Correspondence

PROPOSED INVESTIGATION OF TRAINING AND OPENINGS FOR CRIPPLED SOLDIERS

To the Editor:—I have noted with interest several articles in recent issues of The Journal dealing with the general subject of occupations and training for the physically handicapped. It occurs to me that you may desire to be of some assistance to the Bureau of Vocational Guidance in a proposed survey of this field.

In cooperation with several organizations of national importance, we are considering an investigation of training and possible industrial openings for crippled soldiers and others who are physically handicapped. Our work would probably culminate in a publication dealing with the methods of reeducation used both in the United States and abroad, an account of the general occupations open to each class of the handicapped, and an intensive study of actual opportunities in some one section of the country, probably New England and some of the neighboring states. Funds will probably be available for investigation and publication.

Can you inform us of any other investigations of like character now going on, or can you give us the names and addresses of individuals or associations who would be likely to cooperate with us, or furnish us valuable information?

Any suggestion that you care to make regarding such an investigation, as to either method or scope, will be gladly received.

Please be assured that we will be very grateful for any assistance you may be able to render.

Roy W. Kelly,
Director, Bureau of Vocational Guidance, Harvard University, Cambridge, Mass.

STANDING OF ENGLISH MEDICAL WOMEN IN WAR WORK

To the Editor:—I am enclosing a copy of a letter received from Flora Miller, director in charge, Military Hospital, Endell Street, London, in reply to a request for exact information regarding the standing of the English medical women in the war work. As it is the first definite news that we have been able to obtain on this subject, we think it would be of interest to the public, and so ask you to reproduce it in The Journal.

Louise B. Deal, M.D., San Francisco.
Secretary, Organization of Women Physicians for Federal Recognition.

In reply to your letter to Dr. Garrett Anderson, I have pleasure in giving you the following facts about the employment of women doctors by the War Office.

The medical staff of this hospital is appointed by the War Office, and has entire charge and control of the hospital. The staff is graded and paid according to rank, namely, as Major, Captain or Lieutenant. None of us are commissioned, as a commission cannot be held by women under the present Army act of Great Britain, and as women cannot be attested or sworn in under that act.

We are given the position of officers with the pay and allowances of R. A. M. C. officers. In other military hospitals many women are employed. Some of these are graded and paid according to rank as we are here. Others are engaged as civilian practitioners at a flat rate of 24 shillings [$5.76] a day without uniform or other allowances. It should be noted that there are men doctors in military hospitals engaged on these terms also. Men so engaged are ineligible for general military service, and the War Office has a habit of regarding women as also ineligible for general service.

Our staff here has certain privileges. It is permanent and cannot be moved about by the War Office, and each member except Dr. Garrett Anderson and myself has an opportunity of terminating her appointment every six months.

WHAT FACILITIES DO HOSPITALS AFFORD FOR THE RECEPTION OF SPECIAL INTERNS?

To the Editor:—A committee representing all the associations of otolaryngologists on this continent has been at work for some years, in the endeavor to standardize the training of those who desire to enter on this specialty.

In contradistinction to the ophthalmologists, the committee is not proposing an examination for license by a federal board, but favors the obtaining of a special degree, D.Sc. (Otolaryngology), from the postgraduate departments of leading universities, on examination, after the completion of a definite course of training: (1) as an intern of a standard hospital in medicine, or surgery, or both, or a term of years in practice; (2) as intern in the otolaryngologic department of a standard hospital, for eighteen months, and (3) the attendance on a short course in such subjects as special anatomy, embryology and histology, physiology, pathology and bacteriology, neurology and physics in the postgraduate department of the university conferring the degree.

In order to be in a position to lay the scheme before the postgraduate boards of study of the universities, for their consideration, the committee must be informed what facilities are afforded by the hospitals of the continent, for the reception of special interns:

1. The total number of beds in each hospital.
2. The number of these set apart for otolaryngologic patients.
3. Whether these are under a departmental head.
4. Whether there is an intern set apart for this department.
5. The regulations regarding the intern service: Is there: (*a*) a rotation service; (*b*) a lengthy period confined to one department, or (*c*) a graduated term of service—juniors and seniors, etc.?

It hardly needs to be pointed out that should such a scheme as outlined above be brought into operation and be supported by the leading special and general hospitals, such hospitals would be insured a constant succession of satisfactory material, out of which to man the department of otolaryngology with responsible and earnest interns.

The first condition laid down above would make it reasonably certain that the interns in question would be possessed of a sound basic training, and with these, entrance on the special training of otolaryngology would be in no sense an experiment, but a deliberate investment of time, determined on after mature thought.

Moreover, when a rotation system of internship is in operation, the scheme outlined above would not interfere. The rotating intern would still take on the otolaryngologic service for six weeks or two months, acting in the capacity of junior on the service, and receiving much help from the chief intern.

Information as to the number of hospitals which have a regular department of otolaryngology is difficult to obtain. Any general hospital of 250 beds should have at least fifteen beds set apart for such patients, and these would occupy the full time of a houseman, provided he worked also in the outpatient service.

Any information which your readers can supply will greatly assist and will be appreciated.

On behalf of the committee,
D. J. Gibb Wishart, Toronto, Chairman.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE PARESIS OF GUY DE MAUPASSANT

To the Editor:—I desire to know from a neurologic point how De Maupassant is classed. It occurs to me that by reason of the trend in his writings he must have been a sensualist, if not a sexualist, as much that he writes deals with this phase of human frailty. The fact that he died insane leads me to think that he was suffering from some type of sexual perversion. I shall be greatly obliged if you will direct me to the proper source for this information, if such is extant and available.

E. B. Hardin, M.D., Florence, Ala.

Answer.—Guy de Maupassant (1850-1893), the master of the short story, was of Norman extraction, and grew up around Rouen. In his youth he became a clerk in the Ministry of the Marine at Paris, in which he was but an indifferent employee, spending his time on the river as a *canotier*, or in learning the art of novel-writing with Gustave Flaubert. The latter, as Maupassant has testified, taught him to cultivate the faculty of vision as a means of attaining impeccable accuracy of statement, and conciseness of style, so that any object, from a pile of dirt to a human being, might be visualized in a few words. On the development of this faculty, his success as a writer of tales and travel sketches was based. He became the O. Henry of Paris, with the difference that the sexual side of life was glaringly emphasized in Maupassant's stories, a circumstance that added not a little to the success of his books. In personality, he was really a faun with sensual features and Crô-Magnon jaw, the sort of man who would brazenly take leave of companions in the street or on the river in order to visit a bagnio or a waterside brothel. He delighted in obscene effrontery, particularly in shocking high officials or functionaries of the government in the street or a railway station, by vociferating foul-mouthed expressions in a loud and offensive manner. He had a neurotic heredity, and during the last four years of his life developed all the symptoms of a general paralysis, the result of sexual dissipation, the abuse of drugs, and probable syphilitic infection. He attempted suicide in 1892, and died under painful circumstances, July 6, 1893.

Much has been written about the neurotic heredity and insanity of Maupassant, in particular, the Toulouse dissertation of Z. Lacassagne (La folie de Maupassant, Toulouse,

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Evansville, Sept. 26-28, 1917

(Concluded from page 1469)

Tests Used to Detect Malingering

Dr. George F. Keiper, Lafayette: The recent draft for soldiers for the National Army has revealed the necessity of reviewing the tests used to detect malingering. Ninety per cent. of the men have been honest, and responded promptly and truthfully to the tests. The tests fall under two heads—objective, what the examiner hears and sees; and subjective, what the examinee hears and sees. Recruits must have 20/40 vision of one eye and 20/100 of the other, provided no organic disease exists, and their hearing must be 10/20 of normal. The Duane test, the Snellen test, the Graefe-Baudry, the Todd and many others are used for simulated blindness, while for hearing, the Weber-Kerrison test, and Bárány noise apparatus are among those used. With these, malingering may be detected in a great majority of cases. Some may baffle the surgeon for a time, but if persisted in they will ultimately come to light.

DISCUSSION

Dr. E. M. Shanklin, Hammond: My work along this line has been in connection with the various industries of our region, in which I have to deal with many foreigners. We have always had to contend with some members of the legal fraternity, and since the inauguration of the industrial board, the "ambulance chasers" have taken to instructing their clients how to evade the examinations. However, we are usually able by some of these tests to find the malingerer.

Prostatic Hypertrophy

Drs. W. N. Wishard and H. G. Hamer, Indianapolis: This may involve the entire organ, or the increase in size may be confined to one lateral lobe or to the median portion. Of greater importance than the size is the change it works on the outlet of the bladder. The symptoms of prostatic hypertrophy are those mainly due to mechanical obstruction, but are augmented by infection producing pain and frequency of urination. The severity of the symptoms ordinarily bears a direct relation to the character and degree of obstruction, although this does not necessarily indicate the size of the growth, as the growth may be a small, pedunculated middle lobe acting as a ball valve obstruction and producing complete retention; and if the element of infection is added, the symptoms of pain and desire to urinate will become extreme; whereas a symmetrical growth may reach an enormous size without producing more than a slight increase in the frequency of urination. The suprapubic operation has given good results, in that bladder function is restored and there is less danger to other structures as well as less interference with the function of other organs. It has fewer complications and is more certain of cure.

Dr. Charles M. Mix, Muncie: There seems to be a lack of interest among the general practitioners in surgery of the prostate, due not so much to lack of knowledge as to the result of unhappy experiences. The general practitioner is in an expectant attitude. Surgery must demonstrate the value of the more recent methods of surgical interference. The best answer is a number of old men in a community who have been relieved and will recommend the operation to other sufferers.

DISCUSSION

Dr. W. N. Wishard, Indianapolis: I am not by any means convinced that surgery of the eye, surgery of the nose and throat, and surgery of the ear is altogether legitimate surgery for the general practitioner. Neither am I convinced that surgery of the prostate is best done by the general surgeon, for the reason that there is a very considerable detailed technic involved in the diagnosis, proper treatment, and in the operation itself, which necessarily is a special department of work. We have today some highly competent general surgeons who have become very good prostatic surgeons. A man must be a skilled cystoscopist before he undertakes to do work on the prostate, and it is important that one should carefully understand, follow and cover as completely as may be other questions of pathology that are involved in the sometimes prolonged preliminary treatment.

Dr. Louis Frank, Louisville, Ky.: The most important elements in the success of prostatic surgery are careful preparation of the patient, wise selection of the anesthetic, and the control of hemorrhage at the time of operation. With care in these directions, the mortality may be very low; without it the mortality will be out of all proportion to what it should be.

Abdominal Wounds in War

Dr. J. Rilus Eastman, Indianapolis: The present war has witnessed important developments in the treatment of abdominal gunshot wounds. In previous wars it was held that gunshot injuries of the abdomen should be treated conservatively, as distinguished from the teaching of prompt operation in civil practice. The old plan of "rest and opium" still has some advocates, but the weight of opinion is in favor of applying in military practice the civil method of immediate operation (within twelve hours) in all penetrating wounds of the abdomen, especially when conditions include a skilled operator, trained assistants, a sufficient armamentarium, and last but not least, an aseptic environment. It is likely that the best explanation of the improved statistics of operation in this war is to be sought in the favorable conditions of the trench, the battle lines being in the main more stable than in former wars and allowing of better preparation for operating near the front. A smooth, undeformed bullet, as a rule, makes a small, easily sutured opening in a hollow viscus, unless the shot is tangential to the intestine. However, such a bullet usually produces an irregular laceration of a parenchymatous organ, the aperture of entrance being smaller and more clear cut than the aperture of exit. Irregularly deformed bullets naturally produce larger and more ragged wounds than do smooth ones. For example, the fragmented nickel or steel mantle partially split off and projecting from the lead center bullet may do frightful damage. Large grenade fragments do not, as a rule, penetrate deeply, but often cause extensive crushing and laceration of the abdominal wall. Small grenade fragments often do very little injury on the surface, but the wound is deceptive, the intra-abdominal injury being more serious. Shrapnel balls often remain impacted in the abdominal coverings, but do comparatively little damage. They rarely completely traverse the abdomen. Before operation is undertaken, simple nonpenetrating injury of the abdominal wall must be considered intelligently; also the question of whether conservative treatment, considering the patient's general state and surroundings, would not be better. Operation is not undertaken unless conditions are favorable for good operating. The general treatment of patients not to be operated on consists in rest in the recumbent position with shoulders raised and knees flexed, thus relaxing the abdominal muscles and giving comfort to the patient. An attempt to move the patient should be avoided, nor should he be permitted to move himself. If moved before operation, the Fowler position should be maintained during transport.

DISCUSSION

Dr. Murray N. Hadley, Indianapolis: What Dr. Eastman said regarding puncture wounds of the abdomen may be applied in civil practice. The first symptom he mentions, that is, the evidence of the presumptive peripheral wound, is all that is required in civil practice for an exploration. However, the points he brought out in regard to kidney and liver dulness and tenderness are all things which should be used by the civil surgeon to determine whether or not he should open the abdomen. It is not always easy to determine just what has happened even when the abdomen is opened.

Dr. W. D. Gatch, Indianapolis: During a street-car strike in Indianapolis a few years ago we had at the City Hospital twelve cases of gunshot wounds in the abdomen within a month, in which I operated under the most ideal circumstances and within half an hour. The total mortality in a small series of my cases is 40 per cent., and I believe the civil mortality ranges about 50 per cent. What Dr. Eastman said of wounds of the bladder was confirmed in these cases. In two cases the bullet had gone right through the kidney and down into the thigh. Both patients recovered.

COLORADO STATE MEDICAL SOCIETY

Forty-Seventh Annual Meeting, held at Colorado Springs, Sept. 25-27, 1917

(Concluded from page 1468)

Cesarean Section in Toxemia of Pregnancy

Dr. L. H. McKinnie, Colorado Springs: I have had twelve cesarean sections for the toxemia of pregnancy without a death. I have been favored in the handling of these cases in that I have seen the patients early, and they came from the hands of good obstetricians whose previous treatment and examinations could be depended on. These women have all had one or more convulsions. I have operated on two women who had had no convulsions before operation. One woman had a small pelvis, and it was expected that there would be more or less difficulty with the delivery. Twenty-four hours preceding the operation, the albumin in the urine had increased rather rapidly, and about ten hours before the operation, casts were found in the urine. The patient complained of slight nausea, and the blood pressure rapidly increased from 130 to 190. Taking into consideration the fact that we expected a very difficult and slow labor, and the patient's rapid increase of toxemia, we decided to do an abdominal cesarean section. This was done without difficulty under nitrous oxid-oxygen anesthesia. About three hours following the delivery she had one slight convulsion. Following this she had an uninterrupted recovery, the blood pressure rapidly decreasing and the albumin and casts clearing up in about seven days. The other case was somewhat similar in history, but had shown for some little time a suspicion of oncoming toxemia. I have delivered thirteen babies, with three deaths, twins of six months, and the one child of eight months.

DISCUSSION

Dr. M. J. Keeney, Pueblo: A young primipara, who has a well developed toxemia of pregnancy which does not improve under a short course of treatment, should be delivered by cesarean section. A study of the blood pressure of these women is very important in deciding on operative intervention.

Dr. Charles A. Ferris, Denver: Cesarean section, at the present stage of its development, is liable to abuse. An abdominal surgeon can open the abdomen of a woman and take out the baby at term with a good deal of ease, although he may not know anything about the obstetric indications for the operation. That is one large avenue of abuse of the cesarean operation, and is liable to bring the practitioner into disrepute. However, cesarean section is a well established therapeutic measure in properly selected cases.

Dr. H. G. Wetherill, Denver: I believe Dr. McKinnie succeeded in his series of cases because he gave these patients nitrous oxid gas. The great majority of the profession is unanimous in agreeing that chloroform should not be given to an eclamptic woman under any circumstances. Ether is certainly not the anesthetic of choice. The reaction on the kidneys and lungs, although slight, constitutes a definite danger, and ether should be avoided if possible. Nitrous oxid gas is the anesthetic of choice in operations on eclamptics.

Dr. W. F. Matson, Denver: I have been in the habit of waiting for a second convulsion before resorting to cesarean section; but we are guided by the case by which delivery might be brought about through the natural channel. A primipara, with a long rigid cervix, who has not had labor pains, should always have a cesarean section. On the other hand, a woman with an easily dilatable cervix, with a left occipito-anterior vertex presentation should be delivered through the natural channel.

Dr. O. M. Shivers, Colorado Springs: I am afraid that if we get too radical along the line of operating on eclamptic patients, general practitioners will be doing cesarean sections for other conditions that should be dealt with by less radical measures.

Acute Perforation of Abdominal Viscera

Dr. Chauncey E. Tennant, Denver: Surgeons have recently shown that in cases of abdominal injuries occurring at the battle front, the mortality of the patients not operated on is nearly three times as great as of those operated on. When these patients are operated on within the first eight hours after perforation, the larger percentage recover. It is imperative to make an early diagnosis, even at the expense of an exploratory operation.

Roentgen Diagnosis of Lesions of the Esophagus

Dr. J. A. Matlack, Longmont: In partial or complete obstruction of the esophagus, the roentgen method of examination is usually satisfactory and conclusive. In the hands of a trained operator the technic is simple, and the procedure is not uncomfortable to the patient. In all cases, final interpretation of the roentgen findings must be made only after careful consideration of all available clinical data.

A Few Difficulties in the Administration of Ether

Dr. D. E. Hoag, Pueblo: One of the best plans to secure complete muscular relaxation is to administer some preliminary narcotic, and to induce anesthesia slowly and evenly. In a large percentage of surgical cases there is a tendency to spasmodic closure of the air-way, and this is best counteracted by keeping the lower jaw pressed forward. Overriding teeth will sometimes prevent the lower jaw from coming forward. Pulling the chin away from the sternum or completely extending the head over the operating table is often of use in obstructed breathing. An artificial air-way is of great help. There are certain postures, namely, the prone and semiprone, in which the trunk weight may tell directly on chest expansion. If breathing becomes much embarrassed or ceases, the patient should at once be placed in the dorsal position, and the ordinary means adopted for restoring breathing. Lip friction, sponging the pharynx and tongue traction are all of help, and in desperate cases artificial respiration or laryngotomy must be resorted to.

Causes of Iritis and Allied Inflammations

Dr. Edward Jackson, Denver: Rheumatic iritis used to be ranked as next to syphilitic in frequency. In nearly forty years of practice, I have seen only one case of iritis arising during an attack of acute articular rheumatism. Focal infection has taken the place of chronic rheumatism in the list of causes. The particular organisms present in iritis are usually staphylococci and streptococci. The experimental work done by Rosenow and confirmed by Brown, Irons and Nadler seems to show that certain strains of streptococci are especially likely to cause iritis. Tuberculosis is the cause of many cases of uveal inflammation that were formerly not recognized as being due to it. Of my twenty-five cases, four were clearly tuberculous. Gonococcus infection has long been recognized as a cause of iritis, but its relative importance has been greatly underestimated. In my series there was but one case due to this cause. Gastro-intestinal autointoxication has of late years been recognized as an important cause of iritis, and treatment based on this view has been markedly successful, so that we might claim the diagnosis established by the therapeutic test. Of my twenty-five cases, five were put down as due to this form of poisoning.

The curative treatment of iritis is chiefly extra-ocular. The cause of the iritis should be ascertained and removed, or its deleterious influence removed so far as possible.

3 *Studies in Nephritis of Children. L. W. Hill, Boston.—p. 267.
4 *Prophylactic Use of Pertussis Vaccine Controlled by Complement Fixation Test. E. J. Huenekens, Minneapolis.—p. 283.
5 Paroxysmal Tachycardia in Childhood. N. W. Brown, Baltimore. —p. 287.
6 Case of Pneumonia of Unusually Short Duration. H. B. Conrad, Baltimore.—p. 296.
7 Case of Pernicious Anemia in Boy of Eight Years. J. L. Morse and S. B. Wohlbach, Boston.—p. 301.

1. **Hunger in Infant.**—The material investigated by Taylor included five premature infants weighing from 1,200 to 2,500 gm., forty full term new-borns under 3 weeks of age, and eleven older babies, five between 1 and 2 months, two between 3 and 4 months, three between 4 and 6 months, and one boy of 2 years with a surgically induced gastric fistula made necessary by the effects of corrosive in the esophagus. The gastric movements of some of the infants were recorded only once; on others as many as twenty observations were made. The results of this work fully confirm Carlson and Ginsburg's report that the stomach of the new-born infant exhibits greater hunger contraction than does that of the adult. In normally developing breast fed babes, hunger is not ordinarily an immediate cause of crying. The average time required for the development of hunger in healthy infants gaining in weight and receiving a known sufficient amount of food is, in prematures, under one month, one hour and forty minutes, with a maximum of two hours and twenty minutes and a minimum of forty minutes; in full term infants under 2 weeks, two hours and fifty minutes, with a maximum of four hours and a minimum of two hours; in infants from 2 weeks to 4 months, three hours and forty minutes, with a maximum of four hours and thirty-five minutes and a minimum of three hours and twelve minutes. Hunger contractions occur in these infants long before the stomach has emptied. Consequently their presence is not in itself an indication that the stomach is ready for food.

2. **Hunger Secretion of Gastric Juice in Infants' Stomachs.**—In this study Taylor shows that there is no appetite or psychic secretion of gastric juice in the young infant. This disproves the present view, which, he says, is based on insufficient experimental evidence. The empty stomach of the hungry babe secretes a gastric juice which often is as acid as that found in the adult's stomach. The more profuse this secretion, the higher is its acidity. It contains pepsin. This secretion is not neutralized in the stomach, but flows out into the small intestine. Regurgitation through the infant's pylorus does not occur. Taylor suggests that therapeutic starvation in acute alimentary disorders and in summer diarrheas may owe its success in part to the heightened tonus of the alimentary tract, and in part to the pouring out of highly acid detoxicating and disinfecting gastic juice into the small intestine.

3. **Nephritis in Children.**—Four methods of testing kidney function in children are discussed by Hill: the added salt and urea test, the phenolsulphonephthalein test, the two-hour renal test, and the determination of the concentration of urea nitrogen in the blood. Of these tests the added salt and urea test is of little practical value in children. The determination of the blood urea is probably of slightly more value. The most valuable of the four tests discussed are the phenolsulphonephthalein test and the two-hour renal test, because they are simple to carry out, and because they give reliable and important information concerning the functional power of the kidney. These two tests supplement each other, and more valuable information can be obtained by using them together than by using either one singly. In general, repeated low functional tests at intervals of a few months mean a poor prognosis. High phenolsulphonephthalein excretion alone does not help one way or the other. High phenolsulphonephthalein excretion, normal blood urea, and a normal response to the two-hour test warrant a conclusion that the process is a mild one, that the kidneys are only slightly damaged, and that there is a good chance for ultimate recovery.

4. **Pertussis Vaccine Controlled by Complement Fixation Test.**—Huenekens' observations in seventeen cases would theoretically justify the prophylactic vaccination against pertussis. In none of the cases treated with small doses could any antibodies be demonstrated. Whereas, large doses, such as recommended by the New York City Health Department, showed antibodies in 44 per cent. of the cases. The freshly prepared vaccines were, apparently, more effective than the stock vaccines, as 60 per cent. of the patients treated gave positive fixation reaction. From this, it may be concluded that it is possible to immunize children against pertussis if sufficiently large doses of freshly prepared vaccine be used.

8 *Appendicitis in Infants. I. A. Abt, Chicago.—p. 641.
9 Effect of Chilling on Experimental Pyelonephritis in Rabbit. H. F. Helmholz and B. Rappaport, Chicago.—p. 658.
10 *Unresolved Pneumonias: What Becomes of Them? J. H. Hess, Chicago.—p. 686.
11 Classification of Finkelstein. J. R. Gerstley, Chicago.—p. 691.
12 Empyema; Simple, Interrupted and Continuous Aspiration. H. M. Richter, Chicago.—p. 696.
13 *Prophylactic Vaccination Against Chickenpox. M. Michael, Chicago.—p. 702.
14 *Five Per Cent. Oatmeal Gruel in Infant Feeding. A. Levinson, Chicago.—p. 707.

8. **Appendicitis in Infants.**—Abt has collected from the literature of appendicitis eighty cases of the disease in infants under 2 years of age. Among the cases occurring among children under 3 months, are two possible instances of prenatal appendicitis. The first was a doubtful case in a newborn baby with an eventration and a hernia into the umbilical cord. The appendix of this patient was removed. The second occurred in a baby poisoned by the ingestion of mercuric chlorid and died forty hours after birth. The necropsy showed that the appendix was congested, twisted and bound to the cecum by numerous adhesions. Eighteen additional cases occurred in infants under 3 months. There were six cases in children from 3 to 6 months of age. Eleven cases occurred in children from 6 to 12 months, and forty cases occurred in children from 1 to 2 years. Manifest chill, which is rare in childhood, is infrequently noticed in the first stage of the disease. Temperature is unreliable. It may be very high, or in some instances it may be subnormal. Pulse usually corresponds to the temperature. When extensive peritonitis occurs, the pulse is rapid, weak and irregular. In adults, as in children, an abatement of severe symptoms sometimes occurs after the perforation of the appendix.

Constipation is the rule and occurs among the more severe types. Diarrhea occurs in the milder types, though both conditions may be present, one alternating with the other. When general peritonitis occurs, and paralytic ileus results, symptoms of bowel obstruction naturally follow. Traumatism or diseases of the alimentary tract occasionally seem to play a part in the production of appendicitis. Infection may take place through the lymphatics, or possibly, in some cases, it may be a direct extension from the cecum. In addition, appendicitis may occur after erysipelas, scarlet fever, pulmonary and pleural infections, tonsillitis and other diseases. Foreign bodies, such as worms in the appendix, may bear a direct causal relation. The blood examination in almost every case shows a polymorphonuclear leukocytosis. When general peritonitis occurs, or where the general defenses of the body are reduced and exhausted by severe sepsis, the leukocyte count may be low.

The diagnosis in young infants is difficult, and the mortality is high. Furthermore, the precise condition is frequently confused with intussusception, intestinal obstruction, diffuse pneumococcic peritonitis, pleurisy, pneumonia, gastro-enteritis, typhoid (rarely), ileopsoas abscess or coxalgia. Tenderness at McBurney's point, if it can be elicited, is of diagnostic importance, but, the appendix in children frequently lies deep, so that tenderness may be greater on the left than on the right side, or it may be deflected upward. Rectal examination is of great importance in such cases. When there is palpable resistance on the right side, in the presence of other symptoms, the diagnosis of appendicitis should be suspected.

10. **Unresolved Pneumonias.**—Hess emphasizes the fact that tuberculosis is frequently a complicating, if not primary factor in many of the fatal cases and unquestionably frequently a factor in delayed resolution in recovered cases. Empyema especially of the intralobular type must be excluded in all cases. Empyema and tuberculosis are the two complications to be most carefully watched for and treated, the former surgically, the latter symptomatically. The rare etiologic factors, such as syphilis, foreign body, metastatic and primary new growths, while uncommon, must not be overlooked. The diagnosis of nontuberculous interstitial pneumonia should always be made with great caution and after exclusion of all other conditions causing similar physical findings.

13. **Prophylactic Vaccination against Chickenpox.**—Thirty-two children in an institution were exposed to chickenpox and were given prophylactic vaccinations. Seven developed the disease, six between thirteen and sixteen days after vaccination. In the other instance the date was not known. Eight developed lesions at the site of vaccination between the tenth and fourteenth day, four of these developed chickenpox. Of the four, who had vaccinal lesions and who developed the disease, three had mild attacks and one a severe attack; of three who did not have vaccinal lesions two had severe and one a moderately severe attack. The ages of all who developed vaccinal lesions were between 2 and 5 years. This is true also of those who had chickenpox, except one girl of 7. It is evident that chickenpox is inoculable, as is shown by the development of lesions at the site of vaccination in eight of the thirty-two children vaccinated. This inoculation seems to take place more readily in young children, for the positive results were invariable in children under 5 years of age.

14. **Oatmeal Gruel in Infant Feeding.**—Levinson urges the use of oatmeal gruel as an important addition to infant food. The 5 per cent. solution is the most efficacious. It can be prepared very simply by washing grits in cold water and boiling for thirty minutes and then straining. Gruel can be given at any age with beneficial results. Its taking increases the appetite of the child, makes the stool homogeneous, and often relieves constipation. The gruel has high iron content. The caloric value of 1,000 gm. is 54 large calories.

Boston Medical and Surgical Journal

15 Neurologic Indications for and against Operation in Traumatic Injuries Affecting Central Nervous System. J. J. Thomas, Boston.—p. 503.
16 *Indications for Operation on Traumatic Head Cases. E. H. Nichols, Boston.—p. 508.
17 *Temperature as Valuable Guide to Diagnosis, Prognosis and Surgical Treatment in Craniocerebral Traumatisms. J. W. Courtney, Boston.—p. 511.
18 *Indications for Laminectomy in Fracture of Spine, with Cord Symptoms. J. B. Hartwell, Boston.—p. 513.
19 *Fractures of Base of Skull at Massachusetts General Hospital. W. J. Mixter, Boston.—p. 518.
20 *Report of Cases of Fracture of Skull and Spine, from Fourth Surgical Service, Boston City Hospital. F. J. Cotton and W. F. Cotting, Boston.—p. 519.
21 Cholecyst-Duodenal Fistula. E. D. Gardner, New Bedford.—p. 523.

16. **Operation in Traumatic Head Cases.**—Nichols summarizes his paper as follows: Uncomplicated edema of the brain almost never requires operation. Slight laceration of the brain with persisting edema sometimes requires operation to prevent cerebral degeneration. Subtemporal method is the best operation. Slight extracerebral hemorrhage seldom requires operation; occasionally demands operation to avoid cyst formation; the operation of choice is always skin bone flap. Extensive extracerebral hemorrhage, from rupture of the middle meningeal artery, with or without focal symptoms, always should be operated on, and always by skin bone flap method. Basilar hemorrhage seldom can be cured by operation. When operation is performed it should be in selected cases, for relief of pressure, and usually by skin bone flap method. Intracerebral hemorrhage cannot be cured by operation, although pressure may be relieved. Fracture of the skull by itself, is of little importance except when compounded, when it may produce meningitis unless made aseptic. All depressed fractures involving the entire thickness of the skull should be elevated.

17. **Temperature as Guide in Craniocerebral Traumatisms.**—Personal experience leads Courtney to declares dogmatically that of all the diagnostic and prognostic manifestations of intracranial traumatisms, the temperature throughout stands supreme in the scale of importance. In intracranial hemorrhage unless the bleeding is very extensive and complicated by coexisting alcoholic intoxication, the temperature soon regains the normal and is seldom elevated more than a single degree throughout the entire course of the case, provided no extensive degree of contusion and no degree whatsoever of laceration be present. In uncomplicated contusion the range of the temperature is equally distinctive. In the generality of cases it rises quickly from the subnormal point caused by shock and may go as high as 102. Almost from the beginning its recessions are striking, a morning fall and an evening rise. In favorable cases the evening range gradually narrows to the normal point, the morning recession to a point but slightly subnormal. Toward the end, in unfavorable cases, temperature and pulse rise together and may reach a very high point.

In brain laceration the initial fall of temperature from shock is of extremely brief duration. The almost immediate trend of the temperature is steadily upward, and in severe cases it may rise to 104 or 105 in a few hours. An early and persistently high temperature after craniocerebral traumatism invariably denotes brain laceration. The occurrence of chills during the course of a case of head injury is not an indication of pus formation. The development of an arachnitic process is marked by a sudden jump in the temperature accompanied by such signs of cortical irritation as delirium, somnolence or great motor restlessness. In cerebral abscess the temperature is normal during a sinister period of quiescence which follows the antecedent activity of the process, and subnormal after an abscess has attained sufficient proportions to cause local manifestations of its presence.

18. **Laminectomy in Fracture of Spine with Cord Symptoms.**—The indications and contraindications for laminectomy in Hartwell's opinion are as follows: Laminectomy is absolutely contraindicated in all cases of fracture of the cervical segment of the spine in which there is a paralysis of the intercostal and abdominal muscles, and is contraindicated in all fractures of the spine, wherever located, with cord symptoms of immediate onset, however slight, if other severe injuries are demonstrable, or if the patient presents or has presented the signs of surgical shock. Laminectomy is contraindicated in cases of fracture of the spine with synchronous cord injury, in which the signs point to a complete crush of the cord, until at least four days have passed—the minimum time in which spontaneous improvement can be expected to manifest itself—and if no spontaneous improvement is shown that operation offers no real hope.

Laminectomy is justifiable in cases of fracture of the spine, accompanied by cord symptoms which do not point to a complete cord destruction, if the patient comes under observation within six hours, and if, during the period of observation, the cord symptoms are progressive. In such cases laminectomy with incision into the cord substance for drainage should be practiced at once. Laminectomy is urgently and immediately demanded in those cases of spinal fracture in which cord symptoms are of slow onset and progressive, and in those cases originally free from cord symptoms, in which medullary signs make a sudden appearance. Laminectomy is indicated in those fractures of the lumbar spine in which the cord symptoms indicate injury to the cauda equina, and in these cases an attempt to suture the crushed trunks should be made. Laminectomy is indicated in those cases of old fractures of the spine in which cord symptoms were originally absent or slight and of short duration, but in which the symptoms of pressure on the cord develop late.

19. **Fractures of Base of Skull.**—Mixter's statistics show that among 209 cases of fractures of the base of the skull treated expectantly there was a mortality of 58.3 per cent., whereas among ninety-two cases treated by operation the mortality was 43.4 per cent. Mixter says that decompression in the proper cases of fracture of the base of the skull markedly lowers the mortality. Localizing signs are of value but are certainly no more important than the evidences of increased intracranial pressure. Operation should be performed as early as possible, as late operations are much less effective. As a rule, the decision for or against operation can be made at once, but in a certain number of doubtful cases it is necessary to wait from six to twenty-four hours in order to observe the increase or decrease in symptoms. If the decision is made to postpone operation or not to operate at all, the patient is sent to the ward and the pulse, temperature and blood pressure watched and the condition of the eye grounds noted at intervals. Epsom salt, by the mouth or stomach tube, and an enema are usually given within a few hours. The general pressure symptoms and the general condition of the patient are of fully as great importance as an indication for operation as any localizing signs.

20. **Fracture of Skull and Spine.**—Of twenty-one cases of proved skull fracture, only seven were operated on by Cotton and Cotting; of these there were no deaths following operation save by way of sepsis—late; while of those not operated on there was one death in a hopelessly smashed case and only one death from alcohol combined with trauma in which operation after three to four days would perhaps have been better. It has been Cotton's rule not to do radical operations early, just to clean up compound damage and to await results. If one operates early there is a large percentage of deaths, occurring with curious accuracy ten or twelve hours after operation, from a combination of shock, uncontrollable leakage of blood and of cerebrospinal fluid. Certain cases like one of subdural hemorrhage cited, growing steadily worse from hemorrhage, must be operated on and take their chance. In the main, however, if one can wait, and one mostly can wait safely from forty-eight to seventy-two hours, then the bleeding has ceased, the shock is over, and one can operate or not, mostly not, without much risk and for definite reasons. Depressed fragments, signs of cortical pressure, persistent slowness in clearing of the mental state, with or without signs of actual pressure, are the indications and the only indications. In the early stages, particularly in base fractures, intracranial pressure is not the sole trouble; when they die it is apt to be from an operation which renews bleeding as it removes pressure, a bleeding from sinuses or little basal veins that one cannot control, which with the added trauma is enough to turn the scale.

45 Erythrodermie Congenitale Ichthyosiforme; Report of Cases and Review of Literature. G. M. MacKee and I. Rosen, New York.—p. 511.

36. **Syringadenoma.**—The case presented by Stokes offers the extremely rare combination of a nevus of the sudoriparous glands with a highly vascular granuloma containing large numbers of lymphocytes, plasma and mast cells in a fibroblastic stroma, suggesting in many ways a granuloma pyogenicum or a vegetating dermatitis. All stages in the histogenesis of such a nevus, according to the conception of origin in epithelial rests and inclusions (Cohnheim), seemed to be represented in the material from this case.

37. **"Gel" Test.**—Eighty-seven Gel tests were made by Strickler and in all, control Wassermanns were also made. In doing the Wassermann, three antigens were employed: cholesterinized beef heart, acetone insoluble lipoids of Noguchi, and alcoholic extract of syphilitic liver. The complement unit was a fixed one, the amboceptor titrated before each test and two units employed; 2.5 per cent. suspension of sheep cells was used. In doing the Gel test, all the serums were subjected to the ammonium sulphate test, while about forty serums were subjected to the acetic acid thorium sulphate test. In this series of eighty-seven serums, fifty-nine patients gave a history of syphilis or had syphilitic lesions; practically all were under treatment. All these serums gave positive Wassermann reactions, while only forty-seven gave positive Gel tests. The serum of twenty-eight individuals suffering with various skin affections and several with no lesions whatever were tested. All gave negative Wassermann tests, sixteen gave negative and twelve serums gave positive Gel tests. Therefore it is Strickler's belief that the Wassermann reaction is the best test for syphilis.

41. **Cutaneous Metastases in Hodgkin's Disease.**—Alderson's patient had Hodgkin's disease involving the cervical, axillary and mediastinal glands, as demonstrated clinically and histopathologically. He developed on both legs hard, immovable, painless, noninflammatory tumors which softened and broke down, leaving ulcers clinically indistinguishable from syphilitic gummas. In spite of numerous negative Wassermanns, including several following two provocative injections of salvarsan, mercury and potassium iodid were administered. The salvarsan-mercury-iodid treatment caused only temporary improvement. Roentgen therapy (Coolidge tube) applied to the lesions, rapidly caused complete filling in of the ulcers. Sections of tissue taken from the edge of one of the ulcers before treatment showed the condition to be metastatic Hodgkin's disease of the subcutaneous tissue and skin.

42. **Herpes Zoster Focal Infection.**—Finding a constant association of zoster with alveolar and tonsillar disease processes, leads Lain to believe that true herpes zoster has its origin in a focal infection.

Journal of Nervous and Mental Disease, Lancaster, Pa.

September, XLVI, No. 3

46 *Symptomatology of Certain Infectious Processes Involving Ciliary Ganglion or Its Connections. L. Archambault, Albany, N. Y.—p. 161.
47 Cerebrospinal Fluid Tests, Especially Gold Reactions in Psychiatric Diagnosis. L. G. Lowrey, Boston.—p. 186.

46. **Symptomatology of Infectious Processes of Ciliary Ganglion.**—In all the cases included in Archambault's paper, the symptoms had an acute onset and followed either evidence of general infection or toxemia or else actual infectious processes about the orbits and nasal fossae. The symptoms were strictly local and repeated neurologic examinations failed to disclose any sign of involvement of the cerebrospinal axis. In Archambault's opinion there can hardly be any doubt therefore that the symptoms observed were dependent on pathologic changes within the orbit. This does not mean that infiltration at the sphenoidal fissure and optic foramen cannot materially interfere with the vascular and subarachnoidean exchanges at the base of the brain and thus determine secondarily more or less functional disturbance referable more particularly to the interpeduncular space and acoustico-cerebellar recess. The nature of the infection in these various cases is difficult to establish even tentatively. In all of them, with one exception, the Wassermann reaction was negative which naturally did not exclude syphilis, and in some of the cases, active antisyphilitic medication was followed by prompt and marked improvement. Even this, however, is not positive proof that the nature of the lesion was syphilitic. In some of the cases specific medication yielded absolutely no results and the condition either remained stationary or cleared up apparently under other forms of treatment. Several of the cases occurred either at the beginning or toward the end of an epidemic of poliomyelitis and some of these patients actually lived in districts from which cases of poliomyelitis were known to have been reported. It occurred to Archambault that these ocular syndromes might possibly represent another clinical modality of poliomyelitis. In most of the cases, the occupation or avocation of the patient was such as to throw undue and persistent strain on the accommodative apparatus.

Archambault concludes that while foci of disease involving the brain stem and more particularly the region of the sylvian aqueduct and corpora quadrigemina undoubtedly do produce, usually along with other symptoms, the accommodation convergence paralysis syndrome, there seems to be little ground for the assumption that this syndrome, occurring as an isolated and purely transitory clinical manifestation, is due to an elective central localization. The fact that this syndrome develops after a number of infectious and toxic states known to give rise essentially to lesions in the peripheral nerves, and that it likewise follows local infectious processes about the orbit and nasal fossa, appears to Archambault to justify the belief that it is dependent on degenerative changes involving either the ciliary ganglia or their immediate connections.

94 Anatomicopathologic Lesions in One Thousand Filipino Children Under Five Years of Age. M. P. Mendoza-Guazon, Manila.—p. 51.
95 *Bacteriologic Investigation of Feces and Bile of Cholera Cases and Cholera Carriers. B. C. Crowell and J. A. Johnston, Manila.—p. 85.

93. **Cholera Carriers and Immunity.**—Schöbl and Panganiban found specific immune bodies in the blood serum of experimental cholera carriers (guinea-pigs and rabbits). Specific immune bodies were found to be absent in the normal bile of a highly immunized rabbit. In confirmation of Viole's findings specific antibodies were found to be present in the gallbladder contents of infected rabbits. The percentage of

takes in guinea-pigs that received preventive inoculation or vaccine treatment was as high as in untreated carriers. Preventive vaccination and vaccine therapy effected no apparent shortening of the duration of cholera carriers in guinea-pigs.

95. **Feces and Bile of Cholera Cases and Carriers.**—The intestinal contents and the bile of 269 cases of cholera and cholera carriers were examined by Crowell and Johnston. In 212 cases of cholera the vibrio was found in the bile in 65.2 per cent. and only in the bile in 5.7 per cent. In thirty-two cholera carriers detected after death, the cholera vibrio was found in the bile in 75 per cent. and only in the bile in 43.7 per cent. In cholera carriers the vibrio was present in the bile in 10 per cent. more cases than in cholera cases and only in the bile in 38 per cent. more than in cholera cases. From this the importance of routine examination of both bile and feces becomes apparent. Five patients that were known to have been carriers before death were examined after death, and only in the one with the shortest period between detection and death (thirty-seven days) was the vibrio found. In that case the vibrio was isolated from the bile only. Thirty strains of nonagglutinable vibrios, isolated from the feces and bile of cholera cases, cholera contacts, and others, have been studied. When first isolated, these were not agglutinated by high titer cholera immune serum. By growth in bile eight of these strains acquired the agglutinability. Five of these eight strains retained this property, and the other three lost it after cultivation for a period of two months. In six cases that were clinically and anatomically cholera, the cholera vibrio was not isolated from either the feces or the bile. Such cases occur in a large series of cholera cases.

2 *Investigation of Trench Nephritis by Means of Phenolsulphonephthalein. A. G. Auld.—p. 414.
3 *Occurrence of Spirochetes in Urine. J. L. Stoddard.—p. 416.
4 *Spirochetes Occufring in Urine of Cases of Pyrexia of Unknown Origin. S. W. Patterson.—p. 418.
5 Acute Syphilitic Meningitis. S. A. K. Wilson and A. C. E. Gray.—p. 419.
6 Eusol Treatment of Wounds Infected with Bacillus Pyocyaneus. P. Turner and G. Richardson.—p. 421.
7 Ionic Medication: Method of Administration. L. Kesteven.—p. 423.
8 Case of Acholuric Jaundice Treated by Splenectomy. R. Hill.—p. 424.

1. **Treatment of War Neuroses.**—Hurst discusses: 1. Exhaustion resulting in neurasthenia and soldier's heart. 2. Emotions resulting in stupor and amnesia, psychasthenia, hysteria, hypersuprarenalism and hyperthyroidism, and exaggerated defensive reflexes: (*a*) stupor and amnesia; (*b*) psychasthenia; (*c*) hysterical symptoms; (*d*) hypersuprarenalism and hyperthyroidism; (*e*) exaggerated defensive reflexes. 3. Shell shock: 1. Pure concussion: (*a*) cerebral concussion; (*b*) spinal concussion. 2. Hysterical symptoms grafted on to organic basis of cerebral or spinal concussion.

2. **Phenolsulphonephthalein Test in Trench Nephritis.**—The cases studied by Auld were young soldiers discharged from the hospitals abroad after the acute symptoms had subsided. As a matter of fact, the test is useless in acute cases. The complete results are based on forty-two selected cases. The routine consisted in making the test soon after the patient's admission, and repeating it at intervals of about three weeks. Concomitantly the blood pressure was recorded. The cases in the second month of the disease showed phenolsulphonephthalein elimination varying from 15 to 50 per cent., or over in one hour. If, within three months from the onset of the disease, the phenolsulphonephthalein excretion rises to 40 per cent., or over in one hour, recovery will be good, even should albuminuria continue for another two months or possibly longer. For part of this time casts may also be present. If, at the end of the third month, the phenolsulphonephthalein excretion be under 30 per cent. in one hour, notwithstanding a slight degree of albuminuria, or with intermitting albuminuria, recovery will be protracted, and in some of the cases unsatisfactory. If, at the end of four months the phenolsulphonephthalein excretion reaches 40 per cent., or over, ultimate recovery is the rule, even should the albuminuria last for several months longer. If the excretion remains persistently low (15 to 30 per cent.) up to the fourth or fifth month, the prognosis is unfavorable without reference to the presence or degree of albuminuria. Several such patients reporting themselves after eight to nine months still presented a low index of elimination and slight albuminuria. As to the final issue, it is difficult to say, but the fact that they all had either normal blood pressures, or slightly over, seems to presage in some of these a favorable result.

3. **Spirochetes in Urine.**—A series of 100 men without history or symptoms of relapsing fever showed intra-urethral spirochetes in 33 per cent. of the cases. If spirochetes of the refringens type are included, the incidence rises to 44 per cent. The spirochetes occurred in about 1 in 2¼ men sick of miscellaneous medical and surgical conditions, and in 1 in 5 of healthy men. Stoddard believes that the variety of organisms makes it improbable that the mere finding of spirochetes in the urine can have any diagnostic value in relation to the relapsing fevers until definite morphologic or other differences are established between the various normal and pathogenic varieties.

4. **Spirochetes in Urine of Cases of Pyrexia.**—Patterson states that spirochetes may occur in: 1. A disease with acute onset with chills and vomiting, pain in the abdomen, usually more marked in the right upper quadrant, with continued fever for several days, often with enlargement of the spleen

and herpes of the lips. The pulse rate is not increased, and is usually slowed to 50 or 60 beats a minute in convalescence. There is a leukocytosis of 12,000 to 25,000 with relative increase in the large mononuclears. The cases, if an attempt is made at diagnosis, come to the base as "appendicitis," or "N. Y. D. abdominal"—the initials "N. Y. D." standing for "not yet diagnosed." In these patients Patterson finds spirochetes almost constantly in the urine. 2. The relapsing type of P. U. O. (trench fever) with the characteristic periodic rises of temperature, myalgic and periosteal pains, and leukocytosis with or without enlargement of the spleen, in which an improving technic has enabled Patterson more and more frequently to find a spirochete in the urine during and immediately after the exacerbations of temperature.

12. **Wound Treatment by Living Cultures of Spore-Bearing Anaerobes.**—The key to the situation according to Donaldson and Joyce depends on two observations: one clinical, the other bacteriologic. The former consists in the fact that cases which smell (and the odor is one of the most characteristic features of these cases) do well, while those which do not make no headway. The bacteriologic observation consists in the discovery that a certain bacillus is apparently constant in the wounds which emit the odor, while it is absent or cannot be recovered from those which do not smell. This bacillus is a spore-bearing anaerobe of a saphrophytic nature and belongs to the proteolytic group of organisms; the group which includes *B. tetani* and *B. edematis-maligni*. Unlike the latter, it appears to be nonpathogenic to the animals experimented on, and, what is of more importance, appears to be nonpathogenic for man when introduced into wounds. Further, it does not appear to set free any toxins injurious to the patient in the course of its action on the dead tissues. For convenience sake, the authors call it the "reading" bacillus. It acts, apparently, in virtue of its proteolytic powers only on devitalized tissue, and possibly on toxalbumins, and appears to possess no power of attacking healthy structures. Special stress is laid on the necessity of recognizing the fact that one of the chief factors which keep a wound septic is the presence of devitalized tissue in that wound. This acts as a base from which pathogenic organisms attack the body.

The surgical or excision treatment of wounds apparently recognizes this, but only aims at removing macroscopically devitalized tissues, and in doing so inflicts a fresh trauma liable to reinfection. For this Donaldson and Joyce propose to substitute the "reading" bacillus in a living form. The organism is probably present in the larger number of infected wounds, but requires more or less anaerobic conditions before it can come into play. These are provided by the pack method of treatment, but the authors are inclined to think that salt is not a necessary adjuvant and plays a very small rôle, if any. This seems indicated by the fact that an inert substance like sphagnum moss for packing gives equally good results. It is essential, however, that the wound be laid wide open in the first instance, exposing every pocket and sinus, so that the packing may completely fill the wound.

13. **Liquid Tight Closure in Wound Treatment.**—For the purpose of bringing fresh solution in contact with as large an extent of the wound cavity as possible, the authors created an ebb and flow in the wound by repeatedly filling it under pressure and allowing the fluid to escape. A catheter was inserted having a hole about its middle discharging in the center of the wound and its lower end tied off. The escape of fluid was obstructed by plugging the wound openings with gauze. Irrigation was regulated by a clip on the tube connecting the catheter with a reservoir. Distention of the wound occurred during the flow, followed by leakage and collapse of its walls when the flow was stopped, thus furthering the mixing of fluids in the wound much as the interchange of gases is promoted in the lungs by the act of breathing. In a sense the wound was made to breathe. This tidal movement in the wound is important. It is essentially a cleansing action. In wounds whose ramifications are many and tortuous this plan is particularly efficacious and has given excellent results. Closely associated with this washing of the wound is its ventilation. Exposing a deep wound to the air is of little avail unless air containing fluids are made to penetrate its depths. This is precisely what tidal flushing does. The technic of the procedure is described in detail.

14. **Radical Cure of Inguinal Hernia.**—In Slattery's opinion the importance of repairing the defect in the fascia transversalis in an operation for the radical cure of an oblique inguinal hernia has never been fully appreciated. Any operation which leaves a large or unsupported defect in the fascia transversalis or interferes with the support which the internal oblique muscle normally affords in the inguinal region must fail. Slattery frees the fascia transversalis thoroughly from the retroperitoneal fatty tissue both upward under the conjoined tendon and downward to expose the deep aspect of Poupart's ligament. The fleshy arch of the internal oblique muscle is retracted and forceps applied to the glistening fascia on the deep aspect of the conjoined tendon so as to draw it into the wound. This fascia brings with it the lower aponeurotic portion of the transversalis muscle. Mattress sutures (three or four generally suffice) are used to approximate this fused fascia and aponeurosis to the deep aspect of Poupart's ligament. It is important that the remains of the fascia transversalis still adherent to Poupart's ligament and the cord should not intervene between the structures opposed.

21. **Subtertian Cerebral Malaria Treated with Quinin and Galyl.**—In six cases cited by Falconer and Anderson galyl was used in association with large doses of quinin. That galyl alone can cause the disappearance of the ring forms of parasite from the peripheral blood stream is shown by two cases cited. The first six cases reported were all seriously ill with definite subtertian cerebral malaria. All the patients recovered, with the exception of one patient who died of a complicating croupous pneumonia. All had received quinin, several of them large doses by the mouth, intramuscularly, and intravenously, without clinical improvement. In all of them, with the exception of the fatal case, the clinical improvement after the administration of galyl was striking and immediate. In none of the cases did the injection produce any unpleasant results, although several of the patients appeared almost moribund before the injection. In one case in which it was considered inadvisable to give quinin, galyl alone caused the disappearance of the parasite from the peripheral blood and produced a striking improvement in the condition of the patient. In another case the patient took quinin in any form with great difficulty, and although she had taken a con-

siderable amount of quinin by the mouth and intramuscularly, ring forms of the subtertian parasite were constantly present in the blood. After the first half dose of galyl there was a notable clinical improvement, but the parasite could still be demonstrated in the blood. After the second dose the parasites at once disappeared from the blood. The disease ran a protracted course, and she developed a periostitis of the left humerus, but in spite of repeated examinations parasites were not again demonstrated in the blood during the rest of her stay in the hospital. The authors conclude that while the results of the combined galyl and quinin treatment have been encouraging enough to justify a further trial, the addition of galyl in no way diminishes the necessity for quinin. In cases in which on account of idiosyncrasy, quinin is impossible a valuable substitute may be found in galyl.

23. **Germicidal Power of Flavine.**—From Hewlett's experiments the germicidal value of flavine comes out very much lower than that stated by Browning and his co-workers. The result with pus is particularly poor and many disinfectants equal or surpass flavine and have the advantage of a much more rapid action.

27. **Mathieu and the Archives.**—The sudden death of Albert Mathieu is not to interfere with the publication of this monthly he founded nine years ago for records of research on diseases of the digestive apparatus and of nutrition. It is to be carried on by his former assistants, J. C. Roux, the internist, and P. Daval, the surgeon. It was one of Mathieu's principles to insist on the close and continuous collaboration between the internist and the surgeon in this line of work. The numerous cases of severe and rebellious enteritis in soldiers in his service during the war threw more light on gastro-intestinal pathology, and he had just finished the revision of the third edition of his textbook with this title when death surpised him.

28. **Idiopathic Dilatation of the Rectum.**—Congenital dilatation of the bladder, colon, and rectum has been a special field of Bard's research. He here describes cases of megarectum in which there was abnormal frequency of bowel movements. In one case, in a man of 48, previously published, the rectum filled the entire small pelvis, extending up to the diaphragm. Except for a tendency to constipation, there had been *no* trouble from this megarectum which was a necropsy surprise, the nature of the tumor not being suspected. In a recent case the diagnosis was made in the clinic. The man of 45 had had for years six or seven daily soft stools. When he had to defecate twice *in* the night, he called it an attack of diarrhea, *but no* medication modified it and there were *no symptoms* outside of the abnormally frequent soft stools. The rectum was much dilated but not so much as in the first case in which constipation dominated the clinical picture. In two other cases of megarectum with the diarrheic tendency there was also megacolon, so that diarrhea with megacolon should not be ascribed to colitis until megarectum has been excluded. In fact, the diarrhea from the megarectum *may* mask the constipation from the megacolon. This may lead to serious mistakes in diagnosis, as in still another case he describes in which various tedious courses of treatment had been futilely applied by different specialists to cure the assumed chronic colitis. This patient was a man of 60, member of a foreign embassy, not at all neuropathic and in good general condition but annoyed at having four or five passages of the bowels during the night, with two *during* the day. Roentgenoscopy showed the rectum abnormally dilated and long and the colon also. In these cases of megarectum, medication to cure the diarrhea had no effect as it did not remove the cause, but great benefit followed lavage of the rectum, rinsing it clean and thus putting an end to the incomplete spontaneous evacuation which was the cause of the frequent defecation. With megabladder, in the same way, there is only fragmented evacuation at a time, and hence the *pollakiuria* with megabladder is exactly analogous to the *pollakicoprosis* with megarectum.

29. **Exploratory Laparotomy with Advanced Cancer of the Stomach.**—Lenoir and Gardin report a case of advanced gastric cancer in which an exploratory laparotomy improved conditions materially. The patient was a woman of 54 who had had for six years symptoms suggesting hyperchlorhydria. Then during the following year, the vomiting and hematemesis became more frequent with other symptoms suggesting malignant disease, including atrocious pains and loss of weight. At an exploratory laparotomy the neoplasm was found too extensive for removal and the abdomen was closed, but prompt and material improvement followed. The pains in the stomach region disappeared for weeks at a time and the appetite returned, the patient gaining nearly 30 pounds. Secretory conditions improved to a remarkable extent, and the general benefit was so great that the diagnosis of cancer was doubted for six months, but then the symptoms returned. The woman lived eleven months after the operation. More than this could not have been anticipated from a more radical operation. Mathieu reported a similar case in 1895; he attributed the benefit to the effect of the operation on the mind. The pains abolished by an exploratory laparotomy, he thinks, must have been of central origin. A number of similar cases are cited, with from two to eighteen months' survival. The effect of the exploratory laparotomy is probably analogous to the influence of a laparotomy on tuberculous peritonitis.

30. **Unfermentable Diet.**—Moruzzi's publication on the advantages of peptonized and fermented whey in treatment of dyspepsia with acid or alkaline fermentations, in adults, was summarized in these columns, July 7, 1917, p. 75.

31. **The Stools with Gastric Insufficiency.**—Goiffon reviews in detail the coprologic signs revealing defective functioning on the part of the stomach. He thinks this is more common than generally believed, and that it may be responsible for both gastric and intestinal troubles. When the stools look brown or black on the surface and a brighter color inside, this, he says, indicates rapid oxidation of the bile pigments, and testifies to intense albuminoid putrefaction. The stools with gastric insufficiency are also liable to contain bunches or filaments of connective tissue and small scraps of potato, and the microscope shows muscle fibers. Treatment is with hydrochloric acid, and it has to be given in doses of from 1.5 to 3 gm. a day. Mathieu used to prescribe it: 20 gm. hydrochloric acid in 180 gm. distilled water. From one to three teaspoonfuls is added to a glass of sweetened water into which the white of an egg has been stirred. This glassful is to be sipped during the meal. The hydrochloric acid even in this amount does not replace the missing gastric juices, but it is enough to start the normal play of the reflexes, so that the motor functioning is restored to normal.

38 *The Declining Birth Rate. E. Maurel.—p. 213.
39 The Rôle of the Flying Surgical Hospital. Doisy and Marcille.—p. 219.

35. **Criminal Abortions.**—This article is by a professor in the university law department. He discusses the legal measures that should be adopted to arrest the increasing *number* of criminal abortions, arguing that criminal *abortion* should be classed with espionage, counterfeiting *money*, anarchy, etc., as the crime against society is more important than the indi-

vidual character of the crime, and the informer should be guaranteed an absolute pardon. "Is the defense of the race," he asks, "of lesser importance than the defense of the money supply?" The birth-control propaganda should be suppressed, as the arguments in favor of birth control apply also to voluntary abortion. Criminal abortion cases should not be given a jury trial, as the jurymen do not realize the social danger of the crime, and they yield to intimidation by the abortionists, usually powerful and always with a protecting backing. Another point which he emphasizes is that a physician cited in a suit for criminal abortion should be relieved of the ban of professional secrecy, so that his testimony can be used against the abortionists "toward whom there can be no professional obligation." The action of the police should be reenforced by granting to medical syndicates, to the services pecuniarily interested, and to associations for increasing the population and to morality propaganda associations, the right to bring suit. Isolated, none of these measures is very effectual, but all together, with penalizing the convicted abortionists, would certainly reduce the number of such cases. The fear of punishment has always been one of the determining causes of virtue. In conclusion, Berthélemy stated that he had submitted this article to various medical and legal authorities, including the Assistance Publique and the Society of Legal Medicine, and obtained their endorsement.

36. **Sodium Arsenate in Treatment of Soft Chancres.**—Goubeau states that he and three other army physicians for a year and a half have been applying in treatment of soft chancre and chancrellous bubo, sodium arsenate in a 2 per cent. alcohol (95 per cent.) suspension. They paint the soft chancre with this daily, and if there is a complicating bubo they inject into it 1 or 2 c.c. of a 1 per cent. aqueous solution of the sodium arsenate, repeating on alternate days. Thanks to this method, the average course of treatment was shortened to nineteen days in 149 cases of chancre without bubo, the cure being complete in from four to ten days in the early cases. The most instructive case was that of a negro from Africa who had had vast soft chancres for over six months, rebellious to arsenobenzol and mercury. Five applications of the sodium arsenate suspension transformed the angry lesions and repair proceeded rapidly with a complete cure in a month.

37. **Shield for Chest and Abdomen.**—Delorme pleads that as the steel helmet has proved so useful in protecting against and attenuating skull wounds, a similar steel guard should be worn to protect the chest and abdomen. He exhibited a model breast plate for the purpose, and urged the adoption of something of the kind. His model is made in two overlapping parts.

38. **The Declining Birth Rate.**—Maurel suggests among other measures to arrest the decline of the birth rate, that pensions should be paid to families in proportion for each child until it becomes self-supporting, and that the parents in their old age should be given a pension proportionate to the number of children they have raised.

September, CXXVI, No. 9, pp. 397-444

40 *Acute Typhoid Meningitis. S. Bonnamour and A. Macrygenis.—p. 397.
41 Camphorated Alcohol in Treatment of Extensive Industrial Wounds; Three Cases. Briau.—p. 404.
42 *Mammitis in Soldiers with Malaria. C. Garin and Coullard-Descos.—p. 410.

40. **Typhoid Meningitis.**—The young woman had a typical typhoid fever except for intense headache, and typhoid bacilli were found in the lumbar puncture fluid. Bonnamour remarks that he knows of only seventeen authentic cases of purulent typhoid meningitis with bacilli in the spinal fluid, and one with paratyphoid bacilli.

42. **Mammitis in Soldiers with Malaria.**—Garin found mammitis in five of 800 soldiers under treatment for malaria, and five other cases have recently been reported by others. The mammitis caused no trouble for several months but as suppuration developed there was considerable pain. In two of the men the other mamma suppurated a month or two after the first. In one case there was secretion of actual colostrum during the course of the suppurating mammitis.

Correspondenz-Blatt für Schweizer Aerzte, Basel

43 *Anatomic Research on the Prevalence of Tuberculosis. A. Reinhart.—p. 1153.
44 *Treatment of Flatfoot. H. v. Salis.—p. 1162.
45 Fungus as Substitute for Cotton to Plug Culture Tubes. B. Galli-Valerio.—p. 1168.
46 Incandescent Electric Light for Improvised Superheated Air Apparatus. Debrunner.—p. 1168.

43. **Prevalence of Tuberculous Lesions in Cadavers.**—Reinhart writes from Berne where for eighteen months he made a special study of all the cadavers (460) at the Pathological Institute, seeking for evidences of tuberculosis. No traces of tuberculosis were found in the 28 newborn infant cadavers, but 29.16 per cent. of 72 children under 16 had manifest tuberculosis, in a progressive stage in all, although only 16.8 per cent. had died from tuberculosis. He cites statistics from other large cities showing from 10 to 42 per cent. with tuberculosis in the child cadavers, the numbers reported on varying from 88 to 848. Reinhart's material confirms the increasing prevalence as the children grow older, only 7.14 per cent. showing tuberculosis under one year. In the adult cadavers, tuberculosis lesions were found in 96.38 per cent. of the total 360. Only in thirteen cadavers was the search negative, and of these, nine were under 30. Other statistics show a range from Beitzke's 51.4 per cent. (Berlin), to Naegeli's 98 per cent. (Zurich). The tuberculosis mortality was highest between 30 and 40, rapidly declining after this age. In 63.9 per cent. of the adult cadavers the tuberculous lesions were in a clinically healed stage, the proportion of these cases increasing with each decade. He does not include small induration of the apex among the positive findings, but he was impressed with the frequent coincidence of these indurations with calcified foci in the bronchial glands on that side. This coincidence was marked in 122 of 230 cadavers. This percentage of 63.9 healed cases is the largest yet published, he thinks. The difference between town and country dwellers was slight, 93.9 per cent. of the 140 town people and 98.1 per cent. of the 211 country dwellers. The tuberculous mortality rate was slightly higher for the latter, 27.37, in comparison to 22.15 per cent., but the proportion of active progressive cases was only 7.5 per cent., in the country people to 14.9 per cent. in the towns. The data presented confirm the wide prevalence of tuberculosis, and that in most people it heals. The data show further that it is doubtful, to say the least, whether tuberculous infection occurs generally before the twentieth year.

44. **Flatfoot.**—Salis refers to what he calls *Spreizfuss*, a form in which the normal arch of the metatarsal bones sags, the curve being downward instead of upward. Insoles do not help this straddling of the bones, but great relief is obtained by a tight cuff worn over the front part of the foot back of the root of the toes. This cuff laces on top of the foot and laces further at the side at the broad end. By this means the arch of the metatarsal bones is forced up into place and held there, maintaining it in a dorsal convex instead of a plantar convex position. Before applying this corset-stuff cuff, he softens the skin of the foot, getting rid of callouses, and corrects the straddle foot with a plaster dressing. During this time the foot cannot be used much. In the milder cases this treatment corrects the trouble completely in a few months; in others the cuff has to be worn permanently. It slips easily on and off.

Annali d'Igiene, Rome

August, XXVII, No. 8, pp. 477-548

47 *The Reform in the Army Ration. F. Rho.—p. 477.
48 *The Army Ration in Italy. S. Baglioni.—p. 487.
49 *The Navy Ration. C. M. Belli.—p. 503.
50 The Morphology of the Hemorrhagic Jaundice Spirochete. D. C. Bianchi.—p. 510.

47. **The Army Ration in Italy.**—Rho says that when the war started every effort was made to give the soldiers the best food possible, and the ration was based on the Voit-Rubner

estimate of the calory needs. But time soon showed that what may be proper for a people of heavy eaters did not suit at all the Italian soldiers, coming from rural homes where meat is not on the every-day menu. Pessimistic sociologists have said that the Italian populace is inadequately nourished from a lack of nitrogenous substances in their diet, and they have cited this as an argument to demonstrate and explain the alleged inferiority of the Latin race. But Rho declares that southern Italy has furnished emigrant labor to the world that can stand comparison with any for the ability to stand fatigue, although bread, vegetables and cereals is the principal diet. Carbohydrates form the main articles of diet in rural populations nearly everywhere from the oatmeal of the Scotch to the potatoes of the Irish and the rice of Asia. Folena's experiments on himself (1912) showed that he could maintain his nitrogen balance with a nitrogen minimum of 28.9 gm. He asserts that it is possible to keep at the normal physical and mental level with a protein intake of only 0.6 gm. daily per kg. of body weight. Rho cites further Chittenden, Hindhede and others and the unfavorable experiences with the excessive meat ration given the Italian soldiers, all tending to show the necessity for reform in the soldiers' ration. A commission of military or militarized hygienists and physiologists was appointed to study the subject. Their report was accepted and acted on, with the saving of 30,000 head of cattle each month as only 60,000 had to be slaughtered instead of the 90,000 called for by the previous ration. The number of calories provided in the new ration does not surpass 3,000—except in winter and for the troops in the mountains—but even this is more than Chittenden regarded as necessary. All the reports from the army and navy are favorable for the new ration during the six months it has been in operation.

48. **The Soldiers' Ration in the Italian Army.**—Lieut.-Col. Baglioni comments on the great difference between conditions in this war and in previous wars when men lived in open camps. There is no longer the necessity for long marches and physical encounters and effort. The men crouch in shelters and get comparatively little exercise, while their nerves are being constantly on the strain. The ration possibly called for in other wars is not needed in this, and does actual harm. Another difference between this and previous wars is that the food cannot always be served directly when cooked, but has to be carried long distances to the men in the shelters. The food undergoes various changes during this transportation, in addition to its getting cold, so that it loses in palatibility. Among the first steps taken to improve on the former ration was the training of large numbers of men to serve as cooks for the special conditions of the present warfare. The meat ration was reduced from 375 to 250 gm. with optional fish or canned meat two days in the week, and 100 gm. cheese instead of meat on Fridays, with a corresponding increase in rice or pastes (macaroni, etc.). Provision was also made for cabbage and other vegetables, and 40 gm. of cheese every day. The ration includes also 15 gm. of lard or oil on the three beef days and 20 gm. on the four days of vegetables. Another form of condiment, he says, which is almost indispensable for Italians is the tomato, and provision is made for 15 gm. daily of the fresh or canned tomatoes, or the extract representing 30 per cent. of the dry residue. Variety is also ensured by 10 gm. of onions, garlic, etc.; pepper and spices, 0.5 gm.; salt 20 gm., and on the days when one meal consists of pastes, 10 gm. of grated cheese are allowed for it. For cooking soups and pottage, portable cookers have been found extremely convenient for the men on the firing line (*casse di cottura*), and they are being used more and more extensively in the civilian population. But they cannot be used for preparation of the concentrated tomato extract, boiling the onions, etc. On this account the military authorities and certain firms put up in cans a mixture of meat, vegetables and tomato juice. The inside of the can is varnished to protect the food against corrosion of the metal. The mixture of fats and proteins in the can is varied by different makers and at different times to avoid monotony. The ration of this is 25 gm. which gives a relish to the macaroni or rice served with it. By the change in the ration thus provided, beef cattle and grain are saved in large proportions while the cheese, tomatoes, potatoes, etc., are domestic products. Camp jaundice rapidly subsided on addition of vegetables to the diet of the men in the advanced posts, as also certain forms of scurvy and nephritis. In conclusion eight pages of tables are given showing the comparative food values. The expense of the total ration, including meat, bread, potatoes, vegetables, cheese, sugar and coffee, averages about 80 cents less per week than the old ration; it averages 2,794 calories to the former 3,013. It is expressly stated throughout the article that this ration applies only to the territorial troops, that is, those not at the front firing line.

49. **The Navy Ration.**—Belli gives the details for the navy, saying that the calories total 3,036. This includes 170 calories from the wine provided the men. Rho has proposed to credit the men not taking wine with the money it would cost, but the proposal met with administrative objections. The details of the navy ration are left in large measure to the discretion of the commanders of the vessels to permit variety.

September 9, XXXVIII, No. 72, pp. 977-991

51 *War Injuries of the Eyes. T. di Giuseppe.—p. 977.

51. **War Injuries of the Eyes.**—Di Giuseppe refers to the fact that wounds of the head are exceptionally numerous in this war, and the eyes are proportionately often injured. In the fighting among the mountains, the scraps of stone broken off and propelled by the explosions increase the danger for the eyes. Another danger to which the soldiers' eyes are exposed is from the trachoma and other eye affections of the men taken prisoners, and from such infections in the trenches just vacated by the enemy. The toxic gases which induce much lacrimation are far less dangerous for the eyes than the usual asphyxiating gases. The latter when they act on the eye long enough deprive the cornea of sensibility and it looks dull but otherwise seems normal for a time. If the injury is severe, small foci of necrosis then develop and, with atrocious pain in the brow, back of the neck and the temples, the eye slowly dies, the eyeball becoming completely atrophied. In his experience, 16 per cent. of the war injuries of the eyes were from machine guns or shrapnel, 50 per cent. from flying scraps of stone, 5 per cent. from trachoma, and 25 per cent. from asphyxiating gases.

52 *The Sugar Content of the Blood at Birth. S. Cannata.—p. 513.
53 *Transient Paralysis of the Arm, with Pain, in Young Children. V. Conterno.—p. 517.
54 *The Value of Bacteriolytic Antibodies in the Cure of Typhoid. A. Zironi.—p. 527.
55 Vaccine Therapy in Acute Infectious Disturbances in Infants and Young Children. P. Ceppellini.—p. 533. To be continued.

52. **The Sugar Content of the Blood at Birth.**—Cannata determined the sugar content of the blood in fourteen newly born infants and in eight from 2 to 5 days old. The method applied was the Lewis-Benedict-Bass technic. The findings ranged from 0.074 per cent. in the first group to a maximum of 0.92 per cent. in the others, fasting, and a maximum of 0.114 two hours after feeding.

53. **Transient Painful Paralysis of the Arm in Young Children.**—Conterno comments on the neglect by the text books of this common trouble in young children. In Broca's compilation of 208 cases, half were one to 3 years old and the others up to 5 years, but girls were affected twice as often as boys. The usual cause is that the child stumbles as it is walking with an older person holding its hand, and the arm is jerked as the adult seeks to keep it from falling. The symptoms are those of a subluxation of the head of the radius, and all trouble vanishes with reduction of the luxation, as a rule. In a few cases, however, merely distracting the child's attention answered the purpose. The child was held close in its mother's arms, the sound arm held against her so that the child was unable to use it while the paralyzed arm was left free, near a tempting toy. The mother and

physician pay no attention to the child, and it soon reaches out its one available hand to seize the toy, and the paralysis is conquered. When this fails, he proceeds to reduction of the subluxation. The trouble is a painful but benign traumatic injury of the head of the radius or memory of such.

54. **Bactericidal Properties of Typhoid Serum.**—Zironi tabulates the findings in about twenty-five cases to demonstrate that the serum in typhoid and paratyphoid has marked bactericidal power for bacilli of both the typhoid and the two paratyphoid groups. This power is marked in vitro in a 1:10 dilution, but is still evident even at 1:50, even when the serum is obtained while the bacilli are still circulating in the blood. He theorizes to explain this paradox, suggesting that bacilli in artificial cultures are frailer than those in the body.

56 *The Avoidable Infant Mortality in Italy. G. B. Allaria.—p. 449.
57 *The Urine Reaction in Infants. M. Flamini.—p. 462.
58 *School Anemia. C. Bracci.—p. 469.

56. **Avoidable Infant Mortality.**—Allaria commences this study of the sanitary prophylaxis for early childhood with a description of Mercuriale's "De Morbis puerorum." It was published at the most brilliant period of the Renaissance, the days of da Vinci and Michelangelo, but the writer had to devote the preliminary chapter to an excuse and justification for his temerity in suggesting that children should be given medical attention and care as well as adults. As late as 1905, G. Mya published a scathing arraignment of society for its disregard of the high infant death rate in Italy. Allaria gives statistics in regard to the infant birth and death rates in various European countries, and proposes various measures for infant welfare work.

57. **The Reaction of Infants' Urine.**—Flamini tabulates the metabolic findings in fifteen breast fed and fifteen bottle fed infants, with the urine reaction and the aspect of the stools. Also of a number of the bottle fed being given calcium lactate. In the bottle fed infants and in the breast fed with bowel trouble, the urine was always strongly acid; the acid phosphates content was always large. In the healthy breast fed the acidity of the urine ranged from 0.1 to 0.6, but in the artificially fed the range was from 1.25 to 4 in the healthy, with two exceptions in which it was 0.6. In some of the bottle fed with bowel trouble it reached 4.5 and 5.8. The phosphate content was much higher in the bottle fed. The bottle fed given calcium lactate showed marked reduction of the acidity afterward, the acidity dropping from 2 to 1.3; from 3.5 to 0.9, or from 4 to 1.4. The infants took without disturbance up to 0.5 gm. of the calcium lactate at each feeding, and Flamini thinks that it might be useful to give calcium lactate as a routine measure to bottle fed babies to enable them to tolerate and utilize better the artificial food.

58. **School Anemia.**—Bracci calls this "scholastic anergy," as anemia is not constant and is usually secondary to the changes induced in the metabolism by the lack of energy. The chief change in the blood is the reduction of the amounts of the two basophile substances of the red corpuscles. The whole trouble is probably some upset in the balance of the glands with an internal secretion. Iron does not act as well as usual in anemia. Arsenic gives better results in these cases, and phosphorus is also useful, and their combination.

62 *Surgical Treatment of Ankylosis. E. M. Olivieri.—p. 57.
63 *Nationalization of the Asistencia Publica. L. J. Facio.—p. 68.
64 *Minor Technical Points in Laboratory Differential Diagnosis. M. Beatti.—p. 69.
65 Oysters. P. Brocca.—p. 72.

62. **Operative Treatment of Ankylosis.**—In this part of Olivieri's study of this subject, he reviews the history, and describes four cases in which he restored the functional use of the elbow by resection. He warns that we must not hesitate to resect widely in these cases, from 5 to 8 cm. of bone as may be needed, especially in the tuberculous cases. Vallas has shown that a kind of new joint may form after simple resection. He had occasion to compare the block of bone cut out at the resection with the necropsy findings in the elbow several years later. The epicondyle and epitrochlea had grown again, and the muscles had regenerated with their points of attachment while the articulating ends of the bones had become covered with a compact tissue resembling cartilage; the capsule had reformed completely, and the synovialis was represented by a series of serous cavities which probably in time would have fused into a single cavity. The resulting nearthrosis was an excellent example of what can be accomplished in the elbow by resection alone. But good results are obtained more promptly and more constantly by opening up the joint, resecting conservatively, and interposing a pad of tissue. This, he declares, is the greatest progress realized to date in the treatment of ankylosis.

63. **The Nationalization of the Asistencia Publica.**—In Paris and Buenos Aires the entire system of hospitals, asylums, municipal lodging houses and other agencies for caring for the sick poor and helpless are under one management, called the Public Assistance. It has been found to work so well, by preventing duplication of effort and gaining the advantages of organization, that E. R. Coni, the leading hygienist of Argentina recently proposed a plan to unify in the same way the public hospitals and asylums throughout the whole country on the same single management system. Facio here endorses the project most enthusiastically, and enumerates a number of additional advantages beyond those to which Coni called attention. The plan is to have the national public health system quite distinct, as at present. This department is for prophylaxis of sickness; the Asistencia Publica is for care of the sick. With a nationalized Asistencia Publica it will be possible to have accessible hospitals and asylums available for each region. One point on which Coni insisted especially was that the national leper asylum should not be placed on a comparatively inaccessible island, as at present planned. If the separation from home has to be absolute, families will not disclose the presence of leprosy. It is much better to induce them to disclose it early by having the leprosorium within a reachable distance and visiting permitted under restrictions.

66. **Kidney Calculi and Radiography.**—Martin reports a few cases to show the danger of relying too implicitly on the roentgen findings when they fail to disclose anything suggesting calculi although the clinical picture indicates something of the kind. Imperfections in the photographic plate may simulate calculi, or gravel may clump and simulate a solid stone. In one such case the pyelotomy revealed only one minute grain which he extracted. The fifth day after the operation a large number of other grains were voided in the urine. The pyelotomy had thus been entirely superfluous as

the "sand" would have been washed out in time, while the fact that the other grains were not found at the pyelotomy shows the inadequacy of opening the pelvis alone for exploring the kidney. Roentgenography showed 4 grains still left in the kidney, and three were still there when examined several months later. Martin then had the young man drink copiously of diuretic beverages and exercise vigorously, jumping, walking on his hands and other gymnastic exercises. This dislodged the minute stones and one by one they were expelled, clearing the urinary apparatus of all suspicious appearances. In a third case, pain and hematuria returned after removal of a calculus by nephrotomy, and a second operation was done. The nerve was then released from cicatricial adhesions and also the kidney. Two hardened glands were found close to the renal pelvis, explaining the roentgen shadows at this point. This second operation put an end to all disturbances.

71. **Leprosy.**—Kraus thinks that there probably is more than one germ responsible for leprosy, as for dysentery. The findings with experimental research have been conflicting, he says. In fact, none of the cultures isolated to date can be regarded as the true culture of leprosy. To date also no specific allergic reactions have been conclusively demonstrated in leprosy. It is possible, however, that the tuberculin tests or something of the kind in the incipient stages might prove positive, and etiologic vaccination give successful results. He adds that Stefanski's discovery of lepra in rats may have something to do with its transmission. Fernandez' research in Argentina has demonstrated the existence of lepra in rats. Kraus cites the experiences in Norway in regard to isolation of the leper in his own house, avoiding all contact with the healthy, as having given the most satisfactory results. The reduction in the number of cases has been so marked that this example can be followed with confidence in other countries. In South America, on the other hand, leprosy has spread widely in recent years as there has been no systematic prophylaxis against it. He urges concerted national and international action in prophylaxis of leprosy, especially in South America.

Acta Scholae Medicinalis Univ. Imp. in Kioto

September 10, II, No. 1, pp. 1-113, German Edition

73 *Primary Diseases of Lymphatic Apparatus. H. Nakamura.—p. 1.
74 *Action on Vessels of the Elements of the Blood. (Die Kohlensäure ist der dissimilatorische Regulator für die Zirkulation der tätigen Organe.) N. Yamamoto.—p. 57.
75 *Lesions of the Tibial Tubercle in Adolescents. (Zur Osgood-Schlatterschen Krankheit.) K. Kawamura.—p. 99.

73. **Primary Disease of the Lymphatic Apparatus.**—Nakamura refers particularly to lymphosarcoma. He comments on the diversity of names that have been applied to Hodgkin's disease, listing nearly half a page of them. He also lists eight pages of bibliography on the subject, and reports in detail six cases from the surgical service at Kioto. He also tabulates the blood findings at different periods in four cases of lymphatic leukemia or pseudoleukemia, and suggests a classification for the primary affections of the lymphatic apparatus which will do away with much confusion, discarding completely the term lymphosarcoma. We then would have three groups: 1, the cases with hyperplasia of the lymphocyte cells. (This group includes lymphatic leukemia and pseudoleukemia); 2, those with hyperplasia of the reticulo-endothelium cells (including Hodgkin's disease, tuberculosis and syphilis), and 3, true tumors. In conclusion he reports a case which seemed to be a transitional form between groups 1 and 2. A colored plate shows the blood findings typical of each group. The discovery of a short, antiformin-fast, thick bacillus in the tumors, lymph glands and spleen in three of four cases of lymphatic leukemia and pseudoleukemia convinced him that these diseases are of infectious nature, not malignant tumors. The coordinated hyperplasia of lymphoid tissues in different organs stamps leukemia as a systemic affection. The leukemic blood changes are the result of the action of some noxious substance circulating in the blood. This starts pathologic proliferation of lymphocytes in lymph glands and spleen. The lymphocytes pile up in the lymph glands and spleen, and stretch them to actual tumors. This is pseudoleukemia, myeloma and Mikulicz' disease. Later, the walls of the vessels, especially the veins, become affected and the lymphocytes get swept out into the blood stream. This is lymphatic leukemia and chloroma.

74. **Action of Elements of the Blood on the Vessels.**—Yamamoto reviews the history of research in this line, and describes much personal work, especially on the rabbit ear. He charts the findings in regard to the vessel-constricting action of the different constituents of the blood, the serum and extracts of blood corpuscles, and discusses the mechanism of the vasodilating influence he found with them. The carbon dioxid in the blood in tests with serum or with extract of blood corpuscles exerted a very intensive vasodilating action. Oxygen and nitrogen did not display any appreciable action on the vessels. Yamamoto concludes from the findings related in detail that carbon dioxid plays an important part as a dissimilation regulator of the circulation in functioning organs. This assumption throws light on the benefit from carbonated baths in cases of disturbance in the circulation with high blood pressure. The carbon dioxid is probably absorbed by the skin, and exerts its influence on the vessels in and close to the skin, dilating them and thus relieving the heart. The waste gaseous product of metabolism in an actively functioning organ, namely, the carbon dioxid, by its irritation of the vasodilators ensures an extra supply of blood at once to the organ.

75. **Lesions of the Tibial Tubercle in Adolescents.**—Kawamura's profusely illustrated article analyzes nine cases of Osgood-Schlatter's disease. The patients were all between 12 and 17, and all but one were boys. In four cases the left leg alone was involved, and in five, both legs. The region of the anterior superior epiphysis of the tibia is peculiarly vulnerable during this stage of rapid growth, and any direct or indirect trauma, a single fall or repeated mild injuries, is liable to lead to fracture of the epiphyseal beak of the tibia or tearing loose of the cartilage. The injury may not cast a shadow on roentgenoscopy, and conservative treatment usually ensures a complete cure. If not, and the disturbances persist, excision may be required. This put an end to all the trouble in the first case reported, the lad of 17 being dismissed in twelve days entirely cured.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

August 11, II, No. 6, pp. 441-532

76 *Unrestricted Practice of Medicine. G. van Rijnberk.—p. 443.
77 The Psychanalysis Method. J. H. van der Hoop.—p. 458.
78 Physiologic Titration of Digitalis Preparations on Warmblooded Animal (Cat). G. den Besten and C. de L. van Wijngaarden.—p. 479.
79 *Hemorrhagic Meningitis from Infection with Anthrax Bacillus. R. de J. de Jong.—p. 484.

76. **Unrestricted Practice of Medicine.**—Van Rijnberk relates that an appeal signed by five dozen persons "who know enough to write their names" was presented to the government asking removal of restrictions to the practice of medicine. The government has appointed two committees to study the subject, one comprising ten of the leading physicians of the country, and the other, some lawyers and the men who have long been protesting against the "physicians' monopoly." The official directions given this second committee are "to investigate what legal restrictions to the practice of medicine should be enforced if the license to practice is not to depend on the possession of a certificate showing the successful passing of the state examination." The directions for the medical committee are "To investigate the expediency (*doeltreffendheid*) of the methods of treatment practiced by the nonlegally qualified practitioners of medicine and the results attained by them." Van Rijnberk comments that the task of the first named committee is to prove that in order to cure disease it is not necessary to know what disease is, nor be able to recognize it, nor know its cause, its course or its outcome, nor what can be done for it; in short, that in order to practice the art of healing, ignorance is trumps. The task given the other committee is ambiguously worded as the term "nonlegally qualified practitioners of medicine" might mean physicians legally qualified in other countries but not having conformed to the requirements of the Nether-

lands laws. The term "practitioners of medicine" (*beoefenaren der geneeskunst*) should not be applied to the quacks who are responsible for the agitation. The medical committee has an interesting field for research before it, he continues. This committee includes a physiologist, a pharmacologist, four neurologists, one internist, one ophthalmologist and an obstetrician, but there is no venereologist and no ear man, although these are the chosen fields of the quacks. He comments on the vast field for their research, remarking in conclusion that the physicians of the Netherlands anticipate their report with much interest and concern.

79. **Anthrax Bacillus Meningitis.**—At the necropsy of the young soldier who had succumbed to fulminating hemorrhagic meningitis, the anthrax bacillus was found in the meninges and spinal fluid and in internal organs. He had helped to slaughter a cow with anthrax not long before. The intense cyanosis, early unconsciousness and speedy death were special features of the case. The first symptoms, pain in right arm and shoulder were noticed ten days after the slaughtering of the cow, and a pustule on the arm and the meningeal symptoms developed the fourteenth, with death the fifteenth day.

80 *Appendicitis and Oxyuriasis. S. Matthiasson.—p. 789.

80. **Helminths and Appendicitis.**—Matthiasson states that he found a living oxyuris in the appendix in three adult women. In each case the appendicitis had been mild and restricted to the interior of the appendix, and all had complained of boring pains in the right iliac fossa for several weeks or months after the first acute attack. The long persistence of these pains, with the comparatively slight pathologic changes in the appendix, impressed him as possibly to be ascribed to the helminths. He cites certain authorities to show that helminths are capable of serving as a possible factor in the development of appendicitis. This might explain the occurrence of appendicitis in several members of one family. In looking over the literature he has been astonished to see that surgeons pay so little heed to the oxyuris as a factor in recurrence of appendicitis. He urges collection of statistics in regard to the prevalence of the oxyuris in cases of appendicitis, and especially in recurrences, and whether expulsion of the helminths aids in warding off recurrence, adding that possibly the oxyuris seeks refuge in the appendix during treatment for worms and thus escapes the action of the drug. He has found naphthalin more effectual than santonin in expelling the oxyuris.

81 *Cholesterol in Pleural Effusion. P. Arnell.—p. 737.
82 *Esophageal Diverticulum plus Dilatation. J. Leffler.—p. 748.

81. **Cholesterol in Pleural Effusion.**—Arnell found cholesterol crystals numerous in the effusion in the right pleura in a man of 25 with minor signs of pulmonary tuberculosis. The pleurisy had a chronic tendency but, notwithstanding the persistence and recurrence of the effusion through six years, the general health kept good and the cholesterol crystals did not seem to cause much subjective symptoms. The crystals glistened in the effusion, as there was up to 0.41 per cent. cholesterol. The albumin content reached 5.23 per cent. The fluid was sterile. The effusion had developed first after a spontaneous pneumothorax and the effusion had evidently been encapsulated by the pleura.

82. **Esophageal Diverticulum.**—In the case described by Leffler, a woman of 34 had extreme idiopathic dilatation of the esophagus and at the same time a pulsion diverticulum on a level with the junction of the second rib with the sternum. Recurring bronchitis with lassitud [illegible] ested [illegible]
monary tuberculosis, and the esophageal [illegible]
casual discovery on roentgenoscopy, as [illegible]

86 *The Physiology of Endogenous Uric Acid. H. F. Høst. Supplement.

83. **Wandering Kidney.**—Johannessen discusses the various drawbacks of the different technics in vogue for operative correction of wandering kidney. He regards Rovsing's latest method as superior to all others. Rovsing has reported 85 per cent. cured and 9.3 per cent. improved in 107 cases without complications and a corresponding 50 and 25 per cent. in 64 cases with complications. Johannessen applied his technic in 11 cases, all in women, and all involving the right kidney. In 5 the kidney had become displaced after a childbirth. Of the 7 uncomplicated cases, 6 were cured and the seventh materially improved. Of the 4 with gastroptosis or other complications, all were improved and 2 quite cured. His experience confirmed Rovsing's statements as to the influence of wandering kidney on menstruation. He has repeatedly found that a bandage to support the wandering kidney put an end to dysmenorrhea. Kümmel has reported a case in which, to relieve the pains, both ovaries and finally the uterus were removed, but the pains persisted until the sagging kidney was restored to place. It is important to give some drug to maintain peristalsis after the operation, as otherwise symptoms suggesting ileus may develop. The kidney should always be examined for calculi, cysts and a neoplasm before fastening it in place, and the ureter tested.

84. **Periarteritis Nodosa.**—Harbitz reports the full details with necropsy of a typical case of this affection, saying that he knows to date of only thirty-five cases on record. The intima and media of the medium and smaller arteries were affected with a chronic proliferation of connective tissue and hyalin, associated with regions of acute involvement of the adventitia. In one of the illustrations the finer arteries on the heart look as if strung with beads. The findings in his case suggest polyarteritis as a more correct designation than periarteritis. The onset is generally acute, in the midst of health in the prime of life, although cases have been known in children and the elderly. It begins with fever, not high but irregular, and pains in the muscles and legs, sometimes in the joints. Then there is fleeting edema at various points, especially in the face. The diagnosis wavers between polyneuritis, polymyositis and trichinosis. His patient was a man of 22 and polyneuritis was the clinical diagnosis. Lassitude and weakness became extreme, the pulse small, irregular and fast at times, modified more than corresponded to the fever. The pains increased and symptoms developed on the part of the kidneys, intestinal tract and heart, and death occurred within the usual period of from two to four weeks. This is the nerve or muscle type of nodular arteritis. In the intestinal type, vomiting, diarrhea and collapse phenomena dominate the clinical picture, suggesting peritonitis. The necropsy findings showing the changes and obstruction in the arteries, and the resulting softening and necrosis readily explain the clinical picture. In some cases the main disturbances are in the kidneys from the start, entailing early fatal uremia. The brain and respiratory apparatus have been mostly spared in the cases to date. The nodular arteries may be restricted to a single organ and the nodules may retrogress; Harbitz has seen findings in cadavers and in animals which prove this. He has found gray nodules along the arteries in the spleen in elderly cadavers, which probably were [illegible] of nc [illegible] teritis. An infectious origin seems

the "sand" would have been washed out in time, while the fact that the other grains were not found at the pyelotomy shows the inadequacy of opening the pelvis *alone* for exploring the kidney. Roentgenography showed 4 grains still left in the kidney, and three were still there when examined several months later. Martin then had the young man drink copiously of diuretic beverages and exercise vigorously, jumping, walking on his hands and other gymnastic exercises. This dislodged the minute stones and one by one they were expelled, clearing the urinary apparatus of all suspicious appearances. In a third case, pain and hematuria returned after removal of a calculus by nephrotomy, and a second operation was done. The nerve was then released from cicatricial adhesions and also the kidney. Two hardened glands were found close to the renal pelvis, explaining the roentgen shadows at this point. This second operation put an end to all disturbances.

71. **Leprosy.**—Kraus thinks that there probably is more than one germ responsible for leprosy, as for dysentery. The findings with experimental research have been conflicting, he says. In fact, none of the cultures isolated to date can be regarded as the true culture of leprosy. To date also no specific allergic reactions have been conclusively demonstrated in leprosy. It is possible, however, that the tuberculin tests or something of the kind in the incipient stages might prove positive, and etiologic vaccination give successful results. He adds that Stefanski's discovery of lepra in rats may have something to do with its transmission. Fernandez' research in Argentina has demonstrated the existence of lepra in rats. Kraus cites the experiences in Norway in regard to isolation of the leper in his own house, avoiding all contact with the healthy, as having given the most satisfactory results. The reduction in the number of cases has been so marked that this example can be followed with confidence in other countries. In South America, on the other hand, leprosy has spread widely in recent years as there has been no systematic prophylaxis against it. He urges concerted national and international action in prophylaxis of leprosy, especially in South America.

75 *Lesions of the Tibial Tubercle in Adolescents. (Zur Osgood-Schlatterschen Krankheit.) K. Kawamura.—p. 99.

73. **Primary Disease of the Lymphatic Apparatus.**—Nakamura refers particularly to lymphosarcoma. He comments on the diversity of names that have been applied to Hodgkin's disease, listing nearly half a page of them. He also lists eight pages of bibliography on the subject, and reports in detail six cases from the surgical service at Kioto. He also tabulates the blood findings at different periods in four cases of lymphatic leukemia or pseudoleukemia, and suggests a classification for the primary affections of the lymphatic apparatus which will do away with much confusion, discarding completely the term lymphosarcoma. We then would have three groups: 1, the cases with hyperplasia of the lymphocyte cells. (This group includes lymphatic leukemia and pseudoleukemia); 2, those with hyperplasia of the reticulo-endothelium cells (including Hodgkin's disease, tuberculosis and syphilis), and 3, true tumors. In conclusion he reports a case which seemed to be a transitional form between groups 1 and 2. A colored plate shows the blood findings typical of each group. The discovery of a short, antiformin-fast, thick bacillus in the tumors, lymph glands and spleen in three of four cases of lymphatic leukemia and pseudoleukemia convinced him that these diseases are of infectious nature, not malignant tumors. The coordinated hyperplasia of lymphoid tissues in different organs stamps leukemia as a systemic affection. The leukemic blood changes are the result of the action of some noxious substance circulating in the blood. This starts pathologic proliferation of lymphocytes in lymph glands and spleen. The lymphocytes pile up in the lymph glands and spleen, and stretch them to actual tumors. This is pseudoleukemia, myeloma and Mikulicz' disease. Later, the walls of the vessels, especially the veins, become affected and the lymphocytes get swept out into the blood stream. This is lymphatic leukemia and chloroma.

74. **Action of Elements of the Blood on the Vessels.**—Yamamoto reviews the history of research in this line, and describes much personal work, especially on the rabbit ear. He charts the findings in regard to the vessel-constricting action of the different constituents of the blood, the serum and extracts of blood corpuscles, and discusses the mechanism of the vasodilating influence he found with them. The carbon dioxid in the blood in tests with serum or with extract of blood corpuscles exerted a very intensive vasodilating action. Oxygen and nitrogen did not display any appreciable action on the vessels. Yamamoto concludes from the findings related in detail that carbon dioxid plays an important part as a dissimilation regulator of the circulation in functioning organs. This assumption throws light on the benefit from carbonated baths in cases of disturbance in the circulation with high blood pressure. The carbon dioxid is probably absorbed by the skin, and exerts its influence on the vessels in and close to the skin, dilating them and thus relieving the heart. The waste gaseous product of metabolism in an actively functioning organ, namely, the carbon dioxid, by its irritation of the vasodilators ensures an extra supply of blood at once to the organ.

75. **Lesions of the Tibial Tubercle in Adolescents.**—Kawamura's profusely illustrated article analyzes nine cases of Osgood-Schlatter's disease. The patients were all between 12 and 17, and all but one were boys. In four cases the left leg alone was involved, and in five, both legs. The region of the anterior superior epiphysis of the tibia is peculiarly vulnerable during this stage of rapid growth, and any direct or indirect trauma, a single fall or repeated mild injuries, is liable to lead to fracture of the epiphyseal beak of the tibia or tearing loose of the cartilage. The injury may not cast a shadow on roentgenoscopy, and conservative treatment usually ensures a complete cure. If not, and the disturbances persist, excision may be required. This put an end to all the trouble in the first case reported, the lad of 17 being dismissed in twelve days entirely cured.

76. **Unrestricted Practice of Medicine.**—Van Rijnberk relates that an appeal signed by five dozen persons "who know enough to write their names" was presented to the government asking removal of restrictions to the practice of medicine. The government has appointed two committees to study the subject, one comprising ten of the leading physicians of the country, and the other, some lawyers and the men who have long been protesting against the "physicians' monopoly." The official directions given this second committee are "to investigate what legal restrictions to the practice of medicine should be enforced if the license to practice is not to depend on the possession of a certificate showing the successful passing of the state examination." The directions for the medical committee are "To investigate the expediency (*doeltreffendheid*) of the methods of treatment practiced by the nonlegally qualified practitioners of medicine and the results attained by them." Van Rijnberk comments that the task of the first named committee is to prove that in order to cure disease it is not necessary to know what disease is, nor be able to recognize it, nor know its cause, its course or its outcome, nor what can be done for it; in short, that in order to practice the art of healing, ignorance is trumps. The task given the other committee is ambiguously worded as the term "nonlegally qualified practitioners of medicine" might mean physicians legally qualified in other countries but not having conformed to the requirements of the Nether-

THE DIET OF PRISONERS OF WAR IN GERMANY

ALONZO ENGLEBERT TAYLOR, M.D.
PHILADELPHIA

American soldiers are in France, others are going, and many more will have to go, unless some unforeseen turn in military, industrial, economic or political affairs brings the war to an early conclusion. Barring extreme crop failure, starvation will not intervene in Germany; of revolution in war-time no one has any hope who knows the German mind from first hand observation. Since we have soldiers on the western front, American boys will inevitably be taken prisoners and interned in prison camps. For us the facts of the management of the German prison-of-war camps will, therefore, hold a personal and urgent meaning. We have, indeed, over one hundred Americans interned in Germany, being fed by our Red Cross. There has been much written of the prison-of-war camps in Germany. Much has been distorted and exaggerated; much has also been concealed. In the broad sense, one fundamental fact holds for the prison of war as well as for the prison of peace; prison life depends more on the character of the management than on prison laws. Nobility of management will make prison life good in a state with the worst of laws relating to the penal institutions; brutality will make a hell of prison life under the best of laws. Of this we have illustrations in this country; a prison hell and a prison haven may exist within the same city. But, the prisoner-of-war problem is something more than this. The prisoner of war is not confined for reason of personal penalization, nor is he the object of reformation. The prisoner of war is a military fact; he represents a reduction in the military forces of his country. He is an industrial fact, since he is potentially and actually a laborer in the service of the enemy. He is a political fact, and can be evaluated in terms of diplomatic units. He is lastly, and unfortunately, a weapon of offense in the hands of his captives, since he may be made the object of reprisal for the attainment of military aims. The subsistence of the prisoner of war is a part of his situation, and has relations to each of the rôles that his capture imposes on him.

In a historical review of the provisioning of the prisoner of war in Germany, three periods must be defined: the period of unorganization, the period of organization and the period of stringency. Throughout, one must bear in mind the five accepted principles of management of prisoners of war in Germany:

(*a*) The possession of prisoners by Germany in greater numbers than those of her subjects in the hands of her enemies gave her a situation of vantage.

(*b*) The fact of a food blockade relieved her of legal responsibility for the subsistence of the prisoners of war.

(*c*) The fact that, through the blockade, Germany could not secure manufactured commodities from the neutral world gave her extraordinary rights over the labor of the prisoners of war.

(*d*) The rules of discipline and control applying to her soldiers under her military law applied to prisoners of war under military rule.

(*e*) Distinctions between prisoners of war of different nationalities were not recognized; "the Allies who fight together must as prisoners of war sleep together, eat together and work together."

The period of unorganization lasted until the close of the autumn campaign of 1914. On the west front, management of prison-of-war camps was regarded by the Germans as well organized in 1915. On the east front, however, the organization broke down under the weight of the huge number of Slavs captured in the late summer of 1915. According to the Germans, the organization was everywhere maintained during the year of 1916. During the present summer the number of prisoners taken by the Germans has been so low that the problem of caring for them cannot have been onerous.

The Germans were taken by surprise at the number of prisoners taken during the fall of 1914. As one officer remarked to the writer, with what he doubtless regarded as fine sarcasm, they were "surprised that the Allies had so many troops to surrender and that they surrendered so readily." Confident that the Imperial Army would march directly to Paris, no particular provision for the care of prisoners of war was contained in the campaign plans of the General Staff. For each new batch of prisoners, it was almost literally true that they had no beds on which to sleep, no roofs over their heads, and no food to eat. Usually this state of unorganization lasted only a few days; but sometimes the quarters, living accommodations and food were almost intolerable for several months. Some prisoners have stated to the writer that they regarded the neglect at that time as purely unintentional due to unorganization; others have the conviction, born of experiences that to them permit of but one interpretation, that malice more than unorganization contributed to the wretchedness of their situation. The writer regrets to feel compelled, from personal observations, to conclude that in some camps and under some commandants, malice was a factor in the regimen. When one considers the number of camps (150 parent camps and thousands of working camps) it is obvious that the chances of getting a brute for a commandant or overseer were not few. In theory, the prisoner of war was supposed to receive the ration of the army of his country, and this was, with his pay, charged against his country, to be paid at the close of the war.

The writer had no personal experience with the prison-of-war camps in Germany prior to March, 1916. All statements of conditions prior to that date rests on the experiences and records of the American Embassy in Berlin, on official German publications, and on statements of German officials to the writer. The stringency in foodstuffs became acute after the arrival of the writer in Berlin; and the conditions of subsistence may be assumed to be about the same now as during the summer and autumn of 1916.

The story of later conditions is of more importance to us than a recital of earlier conditions, since we are most interested in what our fellow men may be expected to encounter and endure in the event of being captured on the western front. The fact that Germany has taken no official notice of the declaration of war by the United States, and has herself made no declaration of war against us, will not prevent the captured soldier from "getting his" if he should fall into the hands of a rancorous Prussian sergeant. The Prussian sergeant is a creature sui generis. Since the Franco-Prussian War, German newspapers have regularly contained accounts of the brutalities of the sergeants to the one-year recruits drilling under them. The one-year recruit was the man of university education. The drill sergeant sprang from the masses. During the single year of military service of the educated German, the uneducated sergeant had the only opportunity of his life to inflict personal indignities on the man of social station above him. German military regulations contained specific provisions designed to control the profanity and indecency of language employed by the sergeant against the recruits. German officers have stated to the writer that the strict military rules applying to the newly captured prisoners were not infrequently violated by the sergeant, in the same spirit in which he used to abuse recruits under his control. Good commandants often had difficulty in controlling the sergeants who were their subordinates; the combination of a harsh commandant and a malicious sergeant spelled suffering for the unfortunate man entrusted to their military care.

The subsistence of the prisoners of war during the first half of the first year was provided on the contract system. When one or five or ten thousand men were taken prisoners, they were sent back of the lines. Later they were sent inward, in accordance with a system of distribution that no German official was ever able, or willing, to make clear to one of us. The heads of the army corps had certain rights; the generals of the battling divisions to whom the captive had fallen had certain prerogatives; the needs of the particular sections of the fatherland for labor were taken into consideration, and the capacities of certain cities or sections to care for large bodies of prisoners were factors of moment. But when all was said and done, some of the prison-of-war camps seemed, like Topsy, to have "just growed up." Certainly, some of the camps were established in places that the present commandants cannot imagine would ever have been regarded as proper locations for a camp. When after a battle, the hundreds or thousands of prisoners arrived at the denominated place, possibly after only a few hours' notice by telegraph to the local authorities, it was up to the local authorities to provide shelter, beds and subsistence. The contract system was the most easy and feasible system, at first sight. Caterers took over the entire feeding of prisoners, at prices ranging from 15 to 16 cents per day. There were at first no regulations of diet officially promulgated; the commandants were supposed to see to it that a proper diet was provided. It was during these first months that the greatest complaints over subsistence arose. It was frankly admitted to the writer by German authorities that in many instances the caterers violated grossly the trust imposed in them by the government, made easy by the lack of inspection service. Indeed, in published protocols of later meetings of the war subsistence bureau, dissatisfaction of the authorities and scientists with the subsistence furnished by the caterers was freely expressed. But, openly, the Germans usually denied that more than nominal abuses existed; and when driven to the wall, would fall back on the "you're another" by describing the British as inventors of concentration camps during the Boer War. The caterers not only confessedly neglected the needs of the prisoners of war, but in some instances they also defrauded the government. The penalty, therefore, sometimes exacted, was to compel the contractor to continue his contract after the period had expired, until restitution was done. As prices were continually rising, to compel a caterer to continue at the old price meant loss to him and profit to the goverment. In many instances this was done until, in the judgment of the authorities, the improper profits had been leeched away. But the prisoner of war had no restitution. The writer has no personal information of the diet of the prisoners of war in Germany during the first year of the war. The records of the American Embassy in Berlin contained no investigations by trained observers. The German government did not maintain a competent department of inspections, and confessedly did not know for many camps exactly what was going on. But from statements made to the writer by men whose judgments, as revealed to the writer in camps with which the writer was acquainted, were fair and just, the food of the prisoner of war during the first year of the war was often badly prepared, entirely disregarded the tastes of the men, and was sometimes deficient in amount.

The first governmental regimen was issued in the spring of 1915, and was, in a certain sense, recognized by the Germans as an admission that the local camp authorities and the caterers had been more or less derelict. The first ration provided that the prisoners of war must receive daily 85 gm. (3 ounces) of protein, 40 gm. (1 4/10 ounces) of fat, and 475 gm. (17 ounces) of carbohydrate, with a total value of 2,700 calories. From the standpoint of quantities, this was an entirely adequate diet for sedentary men. When the prisoners worked, they received 10 per cent. more food. The cost was limited to 16 cents, thus compelling the materials to be chosen from among the few foodstuffs that would furnish the denominated units within the set price. Early in the summer of 1915, the housing and subsistence in the prison-of-war camps were organized, and on the customary basis of German minuteness. Under the commandant of the camp operated a committee composed of subsistence officer, surgeon and paymaster. The service of the surgeon was limited to an inspection of the raw materials and stores, and to a daily report on the taste of the mid-day soup. The subsistence officer had the running of the store rooms and kitchens. The paymaster made arrangements for purchase, though this was often purely mechanical, as the central war department made the chief purchases for the prison-of-war camps. The minister of war appointed a diet expert to exercise supervision over the ration. This was fixed each month for all of the camps, leeway being supposedly allowed to enable the subsistence committees in different camps to take advantage of local markets. If the camp commandant was an efficient man, this arrangement resulted in variety in the diet. (The writer once saw 3 tons of asparagus being cooked for prisoners-of-war.) More often the opportunity was neglected. In June, 1915, a course of instruction for subsistence officers was held in Berlin, under the direct authority of the minister of war. The course was attended by about one hundred officers detailed from the several camps; for a week they attended lectures and demonstrations on the physiology of the diet, the preparation of food and the technic of mass rationing. Germany had possessed considerable experience in civic kitchens; and on this experience the feeding of the prisoner of war was largely founded.

As the expert of the Prison Nutrition Office there was selected, not one of Germany's many recognized workers in nutrition, as might have been expected, since the number of prisoners of war was large and the verdict of history on the care of these men a matter of much importance to Germany. Instead, they selected a man whose experience in matters of nutrition had been largely confined to animal husbandry. The writer learned in his first interview with Professor Backhaus that he was not conversant with the literature of human physiology. He was well versed in animal nutrition from the older standpoint of energy equivalents. He was not acquainted with modern investigations on growth or with the current viewpoint of metabolism. He was practically unacquainted with the considerable work that had been done on adaptation of the diet, and was devoid of any conception of the psychology of rationing. He attempted to ration prisoners of war exactly as one would feed live stock. The knowledge of the nutrition of the human body includes that of the animal body, but it also includes something more; and this something more the director of subsistence of prison-of-war camps did not possess. In rationing human beings, one must not violate the laws derived from the studies of nutrition of animals; but merely to apply the feeding rules of the stock farm is not sufficient in the feeding of men.

In the published report of addresses delivered at the meeting of subsistence officers of the camps, frequent references were made to abuses by caterers. Camp authorities were also urged to permit the prisoners of war to prepare food in accordance with their own tastes as much as possible, a recommendation rarely followed; had it been adopted, much of the dissatisfaction of the prisoners with their rations would have been avoided.

From June, 1915, on, the head office issued over the signature of Professor Backhaus a menu for each month, defining in grams to the decimal place the amounts of each foodstuff that were to be served each day. Certain leeway for adaptation and substitution was permitted, but these had to show on the camp diet sheets that were sent to the central office for record and approval. One by one the contracts with caterers expired or were discontinued, and the camp authorities took over the management of subsistence.

The writer reached Germany in March, 1916, and departed in October. During this period, Germany passed from closeness to stringency in food supplies, and the writer was thus in a position to study the changes in the ration of the prisoners of war that accompanied this transition. While the student of the subject is able to predict an oncoming stringency of food supplies at a considerable distance of time, it is usually not possible to convince those in public authority that such a stringency is imminent, and this was the case in Germany. In March, 1916, the students of the subject realized that a critical situation was impending; but the authorities in charge of food control could see nothing of this until the crisis developed in the markets in May. This was reflected in the prison-of-war menu for June, which displayed a reduction of 40 per cent. from that of the month before.

Even the Germans make mistakes, and even the Germans admit they make mistakes. A famous pope has been credited with the remark that he cared not who conducted the arguments so long as he framed the definitions; and the Germans are willing to make such mistakes as are provided in their philosophy. In the Hegelian system, provision is made for logical and illogical mistakes. The German finds great relief in the reflection that his mistakes were logical. The attitude of the world toward this frame of mind is quite that of the family toward the surgeon who regarded the operation as a technical success though the patient died. One of the most striking differences between Englishmen and Germans lies in this: Englishmen blunder into mistakes, Germans reason themselves into mistakes.

The two mistakes that were responsible for most of the difficulties in the prison-of-war diet were disregard of the psychology of the diet and the selection of potato instead of bread as the keystone of the ration. The last mistake the German authorities made against their own people, and it has been the cause of great misery to them. The crop of 1915 was short on grain, long on potatoes. Two hundred gm. (7$\frac{1}{10}$ ounces) of flour per diem was set as the cereal ration of the German people. The rest went to stock feed. Had the ration been set at 300 gm. (10$\frac{7}{10}$ ounces) per day, where it could have been set, this could have been maintained, as was repeatedly demonstrated by German scientists, involving only the withdrawal of so much grain from stock feed. In June, 1915, the bread ration of the prisoner of war was set at 300 gm. per day. The flour ration issued to the kitchens to be used in the preparation of the food and in the baking of extra bread and cakes was limited to 500 gm. (18 ounces) per week. This amounted to a total flour and cereal ration of about 270 gm. (9½ ounces) per day. There was a stated rice ration of 200 gm. (7$\frac{1}{10}$ ounces) per week, but this was largely on paper, as rice soon became scarce.

As against this was the normal British consumption of 310 gm. (11 ounces), the French and Russian of 400 gm. (14$\frac{2}{10}$ ounces) per day. Entirely apart from the kind and quality of the bread, the prisoners naturally felt the amount to be entirely insufficient. The digestive tract becomes accustomed to a certain bulk of the staple foods. When other articles in the diet do not suit, the few staples become the mainstay. Many of the dishes of German cooking, the French and British could not eat. When, therefore, the bread was low in amount, the deprivation was doubly felt. The same fact held for the entire German people. It did little good to substitute potato, since this disarranged the entire bulk habits of the digestive tract.

As a final misfortune, the supply of potatoes gave out early in the spring of 1916, and the prisoners and population together had to go on short rations of potato as well as of bread. In the early months, bread was on sale in the canteens; later this was interdicted.

The bread of the prison camps was the center of storms that concerned more than quantity, involving also kind and quality. Of the kind of bread served, the amount was later more than enough for Frenchmen, Belgians and British. The bread was a coarse mixture of rye (70 per cent.) and wheat (30 per cent.), dark in color, sour in taste and inclined to be soggy and gummy inside. The American bread faddists who are seeking for ever and ever more laxative breads ought to import, after the war, some of the bread makers of the German prison camps; they certainly have perfected the making of bread that would leave an indigestible residue. The bread was sour in reaction, as in the sour fermentation method of central and eastern Europe. This bread was not necessarily indigestible to much greater extent than our graham bread; indeed, the acid fermentation probably had some action on the starch and cellulose. But it was revolting in appearance and in taste. It is a matter of taste. The German prisoners of war in England used to complain of the constant use of white bread; as late as August, 1916, the writer saw in the prison camps in England pieces of sour black German bread sent over from Germany to the men as delicacies, in response to their appeals for a little of the home bread. The smell of the bread is like the smell of the sod, ineffable. The Russians made no complaint against the bread except that the ration was low. And, when an irate Tommy would take a piece of bread and throw it as far as he could, a Russian would eagerly pick it up and eat it. The British boys did not believe the bread had to be made that way; they believe that the Germans were "rubbing it into them," trying to make the German bread as a penal procedure. When in the fall of 1915 potato was added to the bread, matters only became worse. When the writer visited the camps in the spring of 1916, the bread contained as much as 30 per cent. of potato. In some of the camps, relatively good bread was baked; in many of the camps nothing approaching good bread could be produced. In Parchim, where the commandant was ceaselessly busy doing his best to improve conditions for the men in his camp, the making of bread had been evolved to such an art that the 30 per cent. of potato was entirely concealed, and the bread tasted like a common whole-grain bread of coarse texture. In the final analysis, it was a matter of endeavor; where conscientious effort was expended on the problem, results were secured; where the complaints against the bread were lightly disregarded, conditions remained bad. At the best it was a low grade bread, difficult of digestion.

In June, 1915, a limitation of supplies applicable to all camps was issued by the Department of War. Each prisoner of war was to receive not in excess of 300 gm. (11 ounces) of bread, from 200 to 500 gm. (7 to 17 ounces) of fresh vegetables and 1,000 gm. (36 ounces) of potatoes on the average daily; and weekly 200 gm. (7⅒ ounces) of sugar, 500 gm. (18 ounces) of flour, 100 gm. (3½ ounces) of fat (usually soya oil that lasted until late in the fall of 1915) 200 gm. (7⅒ ounces) of field beans, 300 gm. ($10\frac{7}{10}$ ounces) soya beans, 200 gm. (7⅒ ounces) of rice, 440 gm. (15 ounces) of fresh meat, 100 gm. (3½ ounces) of sausage made of blood and internal organs, 150 gm. (5 ounces) of dried sea fish and 200 gm. (7⅒ ounces) of herring. No butter was provided, and margarin was soon dropped. Since it was the rule to serve the special articles of diet at noon in the form of a thick soup, this left little else than bread and coffee or tea for breakfast and supper. Without butter or conserves, this made a poor and unsatisfying breakfast and supper. ("A breakfast consisting of thin coffee without milk or sugar is really not a meal at all, especially if bread is lacking"—a quotation from an official discussion of the prison-camp fare.) The suppers did often contain potato salad or boiled potatoes with herring or sausage, at the beginning: later the suppers approached more and more the compositions of the breakfast. During the past winter the writer has seen prison bills of fare in this country that were almost identical with the German menu; dry bread with coffee or tea for breakfast and supper, soup for dinner six days in the week. The quality of the foodstuffs was, in the experience of the writer, usually not worse than poor. Naturally the grades were not of the best, but decomposed foodstuffs were not often encountered. The coffee was very poor; at first it was one third coffee; two thirds substitutes; later it was all substitute. The cocoa was a powder of husks that cost 5 cents per pound; milk was rarely seen. The sugar carried the tax, as it was expected that the cost of the ration would be repaid at the end of the war. The fresh fish, usually served once a week, was almost always excellent, and this was the dish most looked forward to by the prisoners. The paucity of fat was one of the most grave defects of the diet. Foods low in fats never seem properly cooked. They digest rapidly, and thus hunger appears too soon after a meal, and the sense of having been well fed is destroyed.

The amount of foodstuffs in the diet of the camps was maintained at the set level until June, 1916. In April of that year the ration was normal, containing: protein, 89 gm. (3⅕ ounces); fat, 30 gm. (1⅒ ounces), and carbohydrate, 510 gm. (18 ounces), with a total of 2,740 calories for a nonworking ration. In June the ration for nonworking prisoners fell suddenly to 1,720 calories: protein, 57 gm. (2 ounces); fat, 21 gm. (¾ ounce), and carbohydrate, 310 gm. (11 ounces). This was evidently the result of the mandate of the food controller, von Batocki, who has just been relegated to private life by the new chancellor. The writer has not seen the diet sheets for all of the months since June, 1916; but from those that he has seen, the intake has never since that time risen from 2,000 calories; and the best available information runs to the effect that the ration since our entrance into the war has not exceeded that amount. This quantity of food was, of course, too low to maintain nutrition. It meant loss of weight, subnutrition, lowering of resistance to infections and other diseases—in short, starvation for some of the men. Many men, on a diet of 1,800 calories, will waste greatly and reach a low level in weight at which they can live on the low intake. The defenders of Ladysmith went for three months on 1,500 calories per day. But the intake of the prison-of-war camps in Germany since June, 1916, must have meant subnutrition for all of the nonworking men who had no other food supply, and death directly and indirectly to some.

It was the German principle of ration of war prisoners, as officially stated to the writer, that Germany under food blockade would give to the nonworking prisoners that amount of food only that was available for the poorest nonworking citizens of the empire. This was also practically the Russian rule; the German and Austrian prisoners were given the ration available for the poorest refugees who had no employment. Any other rule would have implied that the Germans were to keep alive the prisoner of war at the expense of German citizens. It is the conviction of the writer that in the large industrial cities of Germany last summer many individuals did not receive more food than was provided in the prisoner-of-war ration, or any better ration.

The equipment of the camp kitchens consisted usually of a number of large soup kettles, a small stove for roasting, and a hot water boiler. The thick soup was usually served to the men directly, standing in line with bowls in their hands. They usually returned to their barracks to eat the meal, but were permitted to do so in the open. In some camps the soup was served to each barracks in large buckets. There were dining tables in few camps; the men had usually to sit on beds or boxes, or stand while eating. The men were not permitted to have knives or forks, spoons alone being permitted, since it was feared that weapons for escape or attack could be fashioned from knives and forks.

With the lack of knife and fork appeared another characteristic of the noon-day meal that was bitterly resented. The meat allowance was very low, for the past year only a third of a pound per week. But this had to be cooked in the soup, and was lost in the mass. Men thus fed acquire a positive homesickness for the sight, taste and touch of meat; they long for the act of mastication of meat. The animals were usually killed in the camps. Everything was used as food but the horns, hair, hide, hoofs and contents of the alimentary tract. The internal organs were worked up with blood into a blood sausage, whose appearance was confessedly revolting. Beef, pork and mutton were all served, according to circumstances. The bones were crushed, the mass heated, and the fat collected by centrifugation. Frozen rabbits from Australia were served as late as the fall of 1915.

All this did not involve the prisoners of the United Kingdom at all, those of France to no marked extent; but it did concern the Russians and the Serbs, who received no foodstuffs from the outside world. As early as the fall and winter of 1914-1915 the British received practically all their foodstuffs from home, and the French to an extent of over one half of their needs. During the six months the writer was in personal contact with the situation in Germany, the Tommies subsisted almost entirely on the supplies sent from home. The international agreements dealing with war provide that prisoners of war may receive packages of tokens, delicacies, clothes, etc., from home. This comfort package, called by the Germans the "love parcel," was expanded by the British into a full ration package. When fresh fish was served or potatoes boiled in their skins, the Tommies would take their share. Otherwise, one or two things would happen. In good camps, the food allotted to the Tommies would be delivered to their barracks by their messengers, and then turned over to the Russians. In bad camps, this was not permitted, and the food was not prepared for the British. The French and Belgians took more or less of the food according to their taste, to fill out the inequalities and insufficiencies of their food parcels. Some of the German dishes were not so revolting to the Belgians, and as a rule they were more adaptable in the direction of German cooking.

In June, 1916, the question of placing a check on the food parcels was brought up by the minister of war. The camp authorities were flooded with letters of protest from Germans, protesting that Germany permitted the prisoner of war to receive from the outside world food in variety, kind and quantity in excess of that available to the poor Germans under blockade. A movement was inaugurated to compel the government to act in the direction of repression. It was supported by the military parties, opposed by the chancellor and the Foreign Office. At that time the Germans were much concerned over the treatment of German prisoners of war in Russia, and supplies of food were being sent to them in Russia under the auspices of the American Y. M. C. A., whose leading representative in prison-of-war service, A. C. Harte, had accomplished an enormous task of alleviation in Russia and Germany. The fear that any repression of the food parcels to Germany would lead to similar repression on food parcels into Russia undoubtedly tended to deter harsh action on the part of the German military authorities. But probably the most deterring factor in the final decision to impose no conditions on the shipment of food parcels into Germany was the vigorous opposition of Ambassador Gerard. The position of the American Ambassador on all matters involving the rights of the prisoners of war committed to his charge was unequivocal and admitted of no compromise. Supported by Bethman-Hollweg and von Jagow, the demands of Gerard for uninterrupted continuance of food parcels of unlimited contents into Germany was finally agreed to by military authorities. This raised a storm of protest, because the Germans felt that these prisoners should be made to feel the pinch of the blockade. And, of course, through the sentries the Germans knew exactly what foodstuffs were being received by the British prisoners. In particular, the possession of butter by the British prisoners seems always to arouse the Germans' wrath, since butter was the article most scarce and most keenly missed. Ambassador Gerard obtained one further concession, in practice if not in principle. In Ruhleben were a considerable number of civilian Englishmen who had no connections in England engaged in sending food parcels. When the low ration of June, 1916, was first introduced, these men were strictly "up against it." Gerard secured permission for food to be shipped in for them in bulk, not as individual parcels, but as lot shipments of foodstuffs to the American Ambassador, to be distributed to the needy men.

Up to the fall of 1916, the food parcels to Tommies were sent out from the mother country in an unorganized way, by families, associations, clubs, churches and societies. In the autumn of that year, the victualization of these men was organized in London and centralized in one committee. A ration was selected that would conserve well, pass censorship easily, stand transportation, keep well in the camp, and wear with the tastes of the men. The supplies included soap and tobacco, two scarce articles in Germany. Bread was baked in Berne, and supplied by a committee of women organized under Lady Grant-Duff, wife of the then minister to Switzerland, and supplied to every Tommy in Germany. So far as the writer could learn from the prisoners themselves, these food parcels were never appropriated by the Germans. Delivery was often delayed, especially in working-camps. The packages had to pass the censor, outgoing as well as incoming, and this often consumed time. The necessity of censorship can be understood from the statement that on a number of occasions a suit of clothes was removed from a hollowed-out loaf of bread. The writer has recently learned from a nurse who has only lately talked with the Tommies exchanged to Switzerland that the delivery of food parcels continues without loss or difficulties. The shipment of these food supplies packed as individual parcels imposed a serious burden on the German transportation system. Sometimes 50,000 packages a month would be delivered to a camp, and a great many express trains were kept in operation by the parcel shipments to the camps. This led to difficulties between the transportation authorities and the censor's office, since the shipments could have been greatly expedited if the rules of censorship had been less strict. All in all, the food parcels were as much a source of discomfiture to the Germans as they were of sustainment to the Tommies.

The food parcels were also the occasion of internal difficulties in the camps. In order to use their supplies, it was necessary for the prisoners to have facilities for cooking. Coffee and tea required hot water, and many of the tinned foods were meant to be warmed up. In good camps, the men were given free facilities to so serve themselves. They could purchase coal, and they were allowed stoves so long as they were careful to guard against fires. In the bad camps, these privileges were refused, and the most petty obstacles put in the way of the use of these food supplies. In the good camps, men were allowed to share their food with other prisoners. In some of the bad camps, the giving of food to prisoners of another nationality was prohibited. In one of the camps, when on the occasion of an inspection by a member of the American Embassy staff, call was made for complaints, a little Irishman stepped out of line and in a shrill voice demanded: "I want to know why in hill I can't give me extry grub to the sick Frinchmen?" It was in such ways that the camp of good management was distinguished from the camp of bad management. When the men of the American Embassy spoke of a good or a bad camp, they referred not to the material equipment, but to the point of view of the commandant. When the Tommies emptied the tins of food they threw the empty cans into a heap. The Russians, like the bears back of the hotels in Yellowstone Park, would hunt over the cans and lick them clean. In one camp this was forbidden! The tin in the cans became a matter of valuable recovery of the metal to the Germans, so that foods in tin may not now be shipped to prisoners in Germany, being forbidden by explicit regulation.

The writer is advised that the shipments of food to the French prisoners in Germany has lately fallen off, an expression of food stringency in France. This is a matter of very great importance and urgency, since with the extreme prevalence of tuberculosis among the French prisoners, a lowering in the intake of food would have a terrible result. This matter of victualization of the French prisoners is now in the hands of the American Red Cross.

All the camps originally contained canteens, where foodstuffs, tobacco and articles of personal need could be purchased. But since June, 1916, no foods are on sale in the camp canteens. Beer and wine were on sale in most of the canteens. The amounts that could be purchased were very limited; a pint of beer or a half pint of wine two or three times weekly, under strict control. The men prized this privilege very highly, not being teetotalers and not disposed to argue as to the effect of such libation on the statistical expectation of life. The camp authorities were a unit in commending the system. No such system obtained in England, despite the petitions of the prisoners and the favor of the majority of the commandants. Assured that sentiments of prohibition were not at the bottom of the refusal, the writer was forced to regard this as a petty form of reprisal, the only sign of this iniquity he was able to find in any of the British camps. The faults in the British camps, where such existed, were due to lack of organization. The faults in the German camps, where such existed, were usually those of persecution, usually petty, sometimes grave and brutal to a serious degree.

The diets in the working camps were usually much more satisfactory than in the parent camps. Employers knew that if the men were well fed they did better work, though in some instances coming under the observation of the writer, employers tried to secure through terrorism by sentries work that was not warranted by the diet. Naturally, a brutal employer, when in possession of prisoners as laborers, has opportunities in the direction of brutality and coercion not possible in times of peace. And, of course, Germany contains such employers just as other nationalities have them. The control of this abuse by employers lay in official inspection; but the inspection system of the working prison camps was both inefficient and inadequate. The writer observed a number of instances of abuse in the direction of underfeeding in working camps, and the matter was all the less excusable as the men were working largely on rations from home. Generosity in the matter of diet could hardly be expected when the standards of work by which the men were judged were such that in one instance the official time-card of a group of men engaged in cultivation of virgin moorland credited the men with work equaling the value for the day 2½ cents. Ten cents per day was a common rate of payment. The men billeted on farms fared the best. Here the lack of long standing racial hatred between German and English came to the good of the Tommy. After being billeted on a farm for a few months, the Tommies and the families of the peasants apparently forgot that their countries were at war, so far as their personal relations were concerned. The Tommies developed a sort of pigeon German and lived in amity with their employers. Very often the prisoners would share with the simple peasants their delicacies from England in exchange for the eggs and butter that the food controller was vainly trying to extract from the country districts for the benefit of the industrial cities. The French and Belgian prisoners did not fare so well. The French never dropped the hauteur and distance of an ancient racial antipathy. The Belgian never lost the immediate sense of resentment at the sufferings of his innocent people. The Russians had few difficulties, because the peasants were accustomed to Russian agricultural labor in prewar days. Work is the salvation of the prisoner of war. If all the prisoners could be employed in agricultural labor, that would be the best solution of the prison-camp problem.

The second mistake of the German management, as was stated earlier, lay in disregard of the psychology of the diet. In the first promulgation on the treatment of the prisoners of war, issued by the War Department, Sept. 11, 1914, the camp authorities were warned not to disregard the differences in habit and customs that existed between the prisoners of different nationalities, and to pay particular attention to the diet of prisoners. This, however, was not done. Why not? The most common answer given by the camp commandants ran to the effect that they did not have adequate and competent personnel, as the military arm seized all. There was, of course, truth in this extenuation, certainly for the first year. But later the causes of the disregard of the psychology of the diet were of a different nature. One was the feeling of bitterness that developed as the war was not brought to a successful conclusion. "They are allies, they fight together; therefore, they live together, sleep together, eat together; no discrimination; the same for everybody." Such in effect was the answer that the writer has heard time and time again. This was the spirit that promoted the commandants in Wittenberg and Gardelegen to disregard the advice of their surgeons, on the first appearance of typhus, that the Russians must be separated from the British, Belgians and French, with the result that epidemics got under way that should have been checked at the outset. This was the spirit that in many cases prompted the refusal to allow the different nationalities to be barracked separately, desirable on account of the different habits of the Russians and British—for example, in the matter of open windows in the sleeping quarters, highly prized by the British, feared as dangerous by the Russians. This was the spirit that ordered the cooks to cook all the food up in one way, the easiest way, perchance: "Let them be allies in the eating of German prison-camp fare." In such an arrangement the one to come out ahead was the Russian. The problem of feeding a Russian peasant is a problem in solid geometry; his sole concern is that of the third dimension. The writer has heard the most unbelievable stories of the capacity of the Russian alimentary tract, such as the eating at one sitting of 50 quarts of purée of peas by seven prisoners. At home the Russians lived largely on bread and vegetable soup, with little meat or dairy products. In the camps with a low bread ration, low in quantity but to them satisfactory in kind, the Russian was entirely satisfied with camp soup if the amount was sufficient. The poor Belgian was against the diet on constitutional grounds; after what he had been through in his native land, any dish that the German concocted could be nothing else than bad. The average Tommy had the point of view in diet that a luncheon from the joint in Simpson's, a piece of rare meat, a bit of boiled cabbage and a potato, each unseasoned, represented the heaven of gastronomics. The Frenchman was accustomed to the highly concocted and deftly seasoned sautés and made-up dishes that the simplest French woman can do so well, and for the rest was dependent for half his intake on white bread. The line of least resistance was to have separated the nationalities as much as possible, have them install their own cooks, and turned over to them the raw materials, as far as possible, and allowed them to prepare the foods as they desired. This was the system arrived at in the prison-of-war camps in Great Britain as the simplest solution of the problem. This the German caterers refused to do in the first months, because of the reduction of profit to themselves. This the camp commandants, for the most part, refused to do later on, because they would concede no distinctions to the different nationalities.

Later, two more or less valid reasons did develop. One was the size of the camps. With the huge camps running up to forty or fifty thousand, the Russians always greatly predominating, it was less feasible to segregate the barracks or the kitchens. The second related to the utilization of food. The camp authorities were afraid that if the men were given raw materials they would cook what they liked and discard the other articles. For example, when potatoes, field turnips and dried sea fish were issued for one meal, the British would soak out the fish and broil it, boil the potatoes, and throw the turnips away. Therefore, to secure complete utilization, the Germans cooked the three into a thick soup, and the ingredients had all to be eaten or let lie. Cooking up all the materials compelled the consumption of the poorer foods, and reduced the cost of maintenance. And as the supplies became more and more coarse, approximating fodder, the more necessary it seemed to cook them altogether. When an Englishman protested that he could not eat such a mess, the German pointed to the Russian contentedly consuming a double portion, and gave a shrug of the shoulder as much as to say, "If it is good enough for your ally in the contest for higher civilization, it is good enough for you." The more the Tommy fought the diet the more determined the German was to make him eat it, go without, or provide his own food. The Tommy finally settled the row by supplying his own food. The Frenchman, less obstreperous and more dignified, took the food when it displeased him least and pieced out with a half supply from home. The more the western Allies shipped in, the more there was for the Russian. When the Russian peasant has not enough to eat, he stands for all the world like a big hungry-eyed docile calf, locked out of the maternal stall; there is no resentment, only appeal.

The psychology of a diet is made up largely of externalities that, on paper and in fact, are much less important than protein, fat, carbohydrates, vitamins, salt and roughage. But as a matter of experience, taste, palatability and the normal appearance and consistency of the foods are of great importance. The Germans had had long experience with civic kitchens, and citations enough can be made from German writings warning against the effects of monotonous soup rations that lack all individuality as dishes. These externalities of diet are important to the normal individual. They are still more important to the abnormal individual, as may be seen in the daily experience in the sickroom. Now the truth is, the prisoner of war does not long remain normal. The crisis of battle, the terror of capture, the transition of circumstances of living, the depression of patriotism, the gloating of the captor, the abnegation of defeat, the homesickness that becomes a positive nostalgia, the insomnia—these all combine to produce reactions in the nervous system that easily lead to perversions in the physiologic functions. When finally is added to this a diet that does not please and idleness, mental and physical, the average prisoner of war, no matter in what land, lives on the verge of the abnormal. Under these circumstances, the externalities of the diet assume and finally possess an increased importance. The constant row about the preparation of the food kept many of the camps in perpetual uproar. Fault there was on the part of the prisoners of war, in that they sometimes made absurd and exaggerated complaints. But the primary and responsible fault lay with the camp authorities, in failing to recognize how serious would be the results of a constant forcing of an unsatisfactory diet. In particular the constant eating of thick soups gets on the nerves. They looked like swill, they left nothing to mastication, and with this manner of cooking the best tastes of the ingredients were not developed; indeed, the particular tastes of the ingredients were lost. German experts in dietetics knew all this, of course. In one of the official publications dealing with the diet of the German camps, attention was drawn to the fact that constant use of soups as the chief dish caused illness in some individuals. And when they began civic feeding on a large scale last summer, loud and numerous were the warnings to the authorities not to repeat the very faults that had been committed in the prison camp. But the German experts in human nutrition had nothing or little to do with the prison-of-war fare. That was being done on the basis of the model stock farm: the men were dieted precisely like domesticated animals. At the time of highest prices of food in the summer of 1916, Professor Backhaus stated to the writer, "I can feed men brilliantly on 12 cents per day." The cost of our army ration is 42 cents. Even the Russians finally turned against the soup diet.

Wise commandants took a different position, and allowed freedom in the preparation of food. The writer has visited camps where the different nationalities were cooking their food in their own way, with satisfaction and without friction, also without losses to the commissary. It was for the most part merely a matter of consideration versus ruthlessness. We have the same things in some of our institutions. With abundant public funds, good foods are purchased; when prepared, the final product is a swill. With the average camp commandant the cause lay in the constitutional disinclination of the German to permit any individual liberty. The prisoner of war could not be allowed self-management; the authorities must do all the management. Now and then a commandant would see deeply enough to disregard this shell of sophistry, with immediate results for himself and his camp. With the right kind of camp commandants, the subsistence would have been better if Germany had not been short of food; with the wrong kind of commandants, conditions would not have been improved if foodstuffs had been abundant. If Americans are taken prisoners and sent to Parchim, Saltau, Friedrichsfelde or Wahn, they will wonder on what the printed stories of the harsh treatment of prisoners of war are based. But if they are taken to Lemberg, Minden, Langensalza or Schneidemühl, they will find it out for themselves in an unfortunately short time, unless these camps have suffered change of commandants. The German system of military control is bad, in that it tends to harshness in discipline, long notorious in the case of their own troops. When this military system was applied to prisoners of war, it became much worse in the hands of a camp commandant who was bitter because he had been compelled to give up his business to become a reserve officer in charge of a prison camp, or who, retired, felt that the battle of Verdun would have been won if he had been there at the head of a division instead of at the head of a camp of prisoners.

Officers have an entirely different system of rationing. The imprisoned officers run a mess, precisely as in their own armies in active service. The cost is charged, directly or indirectly, against them or their country. The officers of the allied countries were, for the most part, comfortably housed in Germany and were free to run their own mess until foodstuffs became scarce. They were often subjected to reprisals, usually petty but sometimes grave, and these reprisals were occasionally directed against the mess. After foodstuffs became scarce in the spring of 1916 and the rationing system was introduced for the empire, the imprisoned officers were not allowed to purchase food in excess of the amounts allotted to Germans. They imported freely foodstuffs of all kinds, and really fared fairly well. The prices charged for domestic foods were often excessive, and petty restrictions were sometimes placed on the amounts of fuel that could be purchased. The natural tendency in Germany was to treat officers well, an expression of the feeling of caste in a military country where the officer occupies a position of social distinction. But the effort failed for reasons of psychology; the Germans fail in the handling of prisoners of war just as they fail in the administration of colonial affairs. Instead of drawing out the qualities of men, German officials attempt to impress their stamp on them.

In accompanying tables are presented the two weekly diet sheets, which will serve to illustrate the subsistence in the German prison-of-war camps. The first is typical of the period prior to stringency in foodstuffs; the second serves as a contrast, and illustrates the present state of affairs.

TABLE 1.—WEEKLY DIET SHEET TYPICAL OF PERIOD PRIOR TO STRINGENCY IN FOODSTUFFS*

	Gm.	Ounces.		Gm.	Ounces

Legumes	150	5.3			

*Per diem: protein, 57 gm.; fat, 21 gm.; carbohydrate, 310 gm.; calories, 1,720.

It is apparent from these figures that our government must undertake and organize the feeding of Americans who may be taken prisoners of war and confined in Germany. This has, indeed, been already undertaken. Food parcels can be sent in via Berne or Copenhagen, and the system of receipts affords a guaranty that the parcels are received by the prisoners. If food conditions in Germany become stringent, the military authorities may decide to rob the prisoners, reversing their previous decision, just as they reversed themselves in the U-boat campaign. Should the prisoners be robbed of their food parcels, the Allies could have recourse to nothing except reprisals on German prisoners of war—which Heaven forbid, since the western Allies could never, in theory or practice, follow the Germans in reprisals.

PROPHYLACTIC THERAPY FOR RICKETS IN A NEGRO COMMUNITY *

ALFRED F. HESS, M.D.
AND
LESTER J. UNGER, M.D.
NEW YORK

For many years cod liver oil has been regarded as the sovereign remedy for rickets. Its claim to therapeutic virtue rests not only on many years of clinical experience but also on metabolism tests showing its beneficial effect on the retention of calcium. It may be properly regarded as one of the well established therapeutic agents and one which should be widely utilized. It seemed, therefore, worth while to investigate whether its usefulness could not be extended to the prophylactic treatment of rickets.

TABLE 1.—COMPARATIVE INCIDENCE OF RICKETS AMONG INFANTS RECEIVING AND NOT RECEIVING THE PROPHYLACTIC THERAPY

	Duration of Therapy, Mo.	Number of Infants	Infants Not Developing Rickets	Infants Developing Rickets	Percentage Nonrachitic
Oil given (average total 54 ounces)	6	32	30	2	93
Oil given (average total 23 ounces)	6	5	4	1	80
Oil given (average total 21 ounces)	4	12	7	5	58
Oil not given	..	16	1	15	6

No doubt cod liver oil has frequently been employed in individual instances in this way. As far as we know, however, no extensive test, embodying a considerable number of cases and continuous and careful observations, has been carried out. This is the task to which we set ourselves.

For various reasons we decided to carry on the investigation among a negro community, and for this purpose selected a district known as the Columbus Hill district. Our main reason was the fact, agreed to by all, that of all races the negro is most subject to rickets. This tendency is so marked that it may be safely stated that over 90 per cent. of the colored babies have rickets, and that even a majority of those that are breast fed show some signs of this disorder. It is evident that where rickets is so prevalent, an excellent opportunity is afforded for judging of therapeutic results.

Another factor which prompted us to select this district was that a survey of the section had recently been made by the Henry Street Settlement and National League for the Study of the Urban Conditions of the Negro, whom we wish to thank for their cooperation in this work. Thus the economic and living conditions, as well as the morbidity and mortality, had been given particular attention. The economic status of these people, as of all the negro population in the larger cities, may be summed up as very bad. The people pay high rents, earn low wages, and unfortunately have had but meager educational opportunities.

The mortality of the negro in New York City, according to the federal census of 1910, was 25.9 as against 15.3 for the white population. In the state and in a group of selected cities, the ratio was about the same. The mortality among the negro infants in the city was 202 in 1915, and 194 in 1916 for each thousand born, as compared with 96 and 94 among the white population in the same years. The Columbus Hill district, which has a population of about 9,000, bears the unenviable distinction of having the highest mortality of any neighborhood in the city, being New York's "black spot." In 1915 its infant mortality rate was 314 per thousand. Among these deaths respiratory diseases, such as pulmonary tuberculosis, pneumonia, and whooping cough, play a large rôle. This tendency has been noted by the city investigators as well as by the federal census bureau. In view of the fact that rickets is a predisposing cause of these respiratory diseases, it would seem particularly beneficial if this disease could be combated, for the purpose not only of improving the nutritional condition of the infants, but, at the same time, of reducing the infant mortality.

It was determined to give cod liver oil to about fifty babies between the ages of 4 months and a year, and to select, wherever possible, infants of families in which other children had had rickets. Before the oil was given, a careful physical examination of the baby was made, and a history of the case taken, involving the diet of the baby and of the mother, the economic condition of the family, the length of time they had lived in the North, and many other data which might be of interest in this survey. As the result of this investigation, we shall in the near future publish a study of the diet of the negro under urban conditions in the North, and attempt to associate it with the marked development of rickets among the children. We were fortunate in having the services of a nurse who had worked in this district for many years, and who was able to facilitate our access to the homes of these people. At the outset before the oil therapy was instituted, a physical examination was made and repeated at the end of two months, four months and six months, when the test was completed. Visits were frequently made by the visiting nurse and by one of us in order to follow the health of the infants and to assure ourselves that the oil was being taken. As was to be expected, there was a considerable number of mothers who, for one reason or another, were unable to cooperate in the work. These were either dropped absolutely from the list or were viewed as control cases. It so came about that although we began with eighty infants, this number was gradually depleted so that at the end of the period we had only forty-nine cases on which to base our conclusions. There were, on the other hand, compensating advantages. As the negro, in the choice of his home, is limited to certain definite localities, our follow-up work was not ham-

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

pered by the great difficulties which usually beset those who attempt to keep track of people in this great city for a period extending over six months.

Our results are summarized in the accompanying six tables. It is seen that we were able to prevent the development of rickets in more than four fifths of the infants who received the oil for six months, and in more than one half of those who were given it for four months (Table 1). This result must be considered satisfactory when we note that, of the sixteen infants who did not receive oil, fifteen showed signs of rickets, though all of them lived under the same conditions and many in the very same families. No other treatment was given, nor was a change of diet or mode of life attempted which could account for the difference in the results between the two groups of cases. Table 2 shows that the cod liver oil proved to be a more potent factor than breast feeding in warding off rickets, and that almost all the colored babies developed rickets *even though* they were nursed. It is naturally impossible to set fixed boundaries and classifications for different degrees of a disease. In our clinical examinations we were guided mainly by craniotabes, beading of the ribs, and the enlargement of the epiphyses, and classified these signs as of four grades of intensity, which are designated in the tables by plus signs.

It seems unnecessary to go into detail regarding the data appended in these tables. Table 3 shows the results when a large amount of cod liver oil, an average total of 54 ounces, was given for a period lasting six months. Table 4 presents the benefits derived from smaller amounts of oil, an average total of 23 ounces, given for the same length of time. In Table 5 may be seen the effect of administering smaller amounts for a period of only four months, and finally a summary of the clinical course of the control cases among those receiving no oil is given in Table 6. We shall leave a consideration of the details to those who care to study the data of the individual cases. The conclusion, however, seems evident that the negro infants who received cod liver oil for six months regularly ("large amounts" indicate regularity of therapy rather than any increased dosage) are protected from rickets, whereas those who were given no protective therapy were almost certain to develop the disease.

It is difficult to state either the minimum length of time that the oil must be given to accomplish prophylaxis or the minimum dosage necessary. A review of the results as portrayed in the tables, however, shows that a four months' course of treatment, averaging a total of from 16 to 20 ounces of oil, is insufficient to afford protection (Table 5). Among twelve infants

of this group, five were found to show progressive rickets It would seem that six months should be considered the minimum duration of treatment. It is likewise true that no hard and fast rule can be laid down as to dosage. Our plan was to give infants under 6 months one-half teaspoonful of oil three times a day and older infants twice this amount. It was found that almost all babies can take cod liver oil, although it may disagree temporarily and may have to be discontinued for short intervals when there is digestive disturbance. Infants of from 2 to 3 months tolerate the oil in half-teaspoonful doses, and younger ones may be given still smaller amounts. This study was not carried out during the summer months, so that it does not provide a criterion of the practicability of oil therapy in the warm weather. As the result of personal experience gathered at other times, we believe that with slight modification it can be pursued throughout the year. In summer, moreover, rickets seems to pass through a quiescent period; therefore treatment is not so necessary as in the colder season.

After a few months we arranged that instead of having the oil delivered to them, the mothers should call for it at the neighborhood settlement house, for which purpose an office hour was appointed for each morning and one evening a week. The report of this work gradually spread throughout the district, and the ordinary symptoms of rickets became the common knowledge of the mothers, who often brought their babies to the consultation with the request that cod liver oil be administered. In this way a rickets clinic was soon evolved. This would seem to be a logical development—that specialized clinics should be established to meet the particular needs of a given neighborhood. In Italy quinin is dispensed in clinics formed for those suffering from malaria. Along similar lines have been the creation of tuberculosis and cardiac clinics.

As a result of our experience, we would recommend that dispensaries of this kind be provided in large cities in the negro and the Italian districts, for rickets is almost as prevalent among the Italians as among the colored people. Such dispensaries do not have to be created at large expense. They can be instituted in connection with existing milk or baby welfare stations, where provision can be made for dispensing cod liver oil. The details of this plan cannot well be discussed, as they will no doubt differ according to special conditions. Whether it is necessary to use Norwegian oil is very doubtful; it is probable that a less expensive cod liver oil will produce equally good results. In order to combat the high infant morbidity and mortality among the negroes of the Columbus Hill district, Commissioner Emerson of the Department of Health will establish a rickets clinic this fall in connection with its baby welfare station, and will dispense cod liver oil at cost.

ABSTRACT OF DISCUSSION

Dr. Haven Emerson, New York: We have been fortunate in New York in having the direct benefit of the whole series of Dr. Hess' rather striking experiments, not only the laboratory experiments with the experimental animals, but the observations in the institutions which he has under his control; and now these field experiments, in the very areas in which we have been attempting to make an impression on a racial problem of rickets. I will leave it to Dr. Sobel to tell you what has been done in meeting the problem among the colored children; but I think it is well for us to consider this report of Dr. Hess as a very important addition to our knowledge of so-called racial susceptibilities to disease.

We have been always told that the Italians and the colored people were racially susceptible to rickets. On a closer analysis it may easily prove to be that what we have put down as a racial susceptibility is merely a result of economic habit—their habits changing radically when they move from their normal habitat in the West Indies to an abnormal housing and economic condition in this city. The colored people buy the most expensive cuts of meat. They are apt to get meat that many of us would hesitate to buy for our own tables because of the high cost of it. Their racial habits of buying and preparing food may easily be the reason of this so-called racial idiosyncrasy to rickets.

Dr. Hess has suggested, and brought it already to the attention of the department of health, that we should dispense cod liver oil from the baby health stations. I think those of you who are responsible for public health administration realize how many are the requests for using the health department organization to promote or exploit some special substance. It would be just as logical to dispense sugar of milk or limewater at cost, or some of the proprietary foods which are found valuable in difficult feeding cases. The department of health has had to refuse to do that; but it is possible to see that a pure cod liver oil is furnished at the local drug stores.

Dr. Hess did not tell you one of the interesting results of his study and teaching. The mothers are now coming to his clinic saying: "I want to have cod liver oil for my baby." He asks them, "Why do you want it?" "They have little swellings around the end of the long bones; they have got little lumps on their wrists." The mothers are beginning to realize what is happening to the babies. He has carried on a campaign of education which is going to redound to the benefit of all the colored babies and diminish the death and sick rate of these children in a variety of ways.

Dr. J. Sobel, New York: No one is more interested in the infant mortality problem, probably, than I am; and any contribution along those lines, of course, is entirely welcome. We have a very definite infant mortality problem in New York City as far as the colored people are concerned. When I tell you that in 1915 the infant mortality rate per thousand births among colored children was 202 as against 96.1 for whites, and that in 1916 it was 193.3 against 91.2 for whites, in other words, that the infant mortality among the colored was 110 per cent. more than among the whites, you will understand readily that we have a definite problem to cope with. In the section that Dr. Hess is working in, the Columbus Hill district, or the San Juan district, as it has been termed because of the "peaceful" character of the population, the infant mortality is 314; and that naturally led to a great many observations, not only on the part of the department, but along Dr. Hess' lines. Rickets, of course, is a contributing factor toward infant mortality and predisposes the child to diseases of the respiratory tract, and to gastro-intestinal diseases, to say nothing of the occasional cerebral involvements; and if we can control rickets, we will diminish infant mortality along those particular lines. This is only a small proportion of the mortality, however, since I learned this afternoon that the infant mortality rate among the colored for congenital diseases was 71 as against 41 for the entire city.

As I look at the table of Dr. Hess I may be wrong, but I find in that table one of the most potent arguments for the increased feeding of babies with milk, rather than with cod liver oil. We find here that the mothers and, coincidentally, the babies get a large protein intake, that is, a large meat intake and a large egg intake, a comparatively good vitaminic intake in the form of fruits and vegetables, a fairly large corbohydrate intake, but a very low fat intake. The milk and the cocoa are practically the smallest intake of the people; and that shows us what we found out years ago, that one of the main causes of rickets is the deficiency in fat. We know that rickets is more common among children who take patent baby foods with a large carbohydrate content. If cod liver oil is a prophylactic agent against rickets, it probably works not specifically, but rather through its fat content; and if I can give the colored people an extra bottle of milk a day, I think that I would do a great deal better than by giving them cod liver oil; and, what is more, I know they will buy the milk in preference to the cod liver oil; in fact we have already had a great deal of difficulty in having these people purchase cod liver oil. I don't mean to say that they will not take it if we give it to them for nothing; but, as far as purchasing cod liver oil is concerned, it is a different proposition. As I see it, while, as a supplemental treatment, or a supplemental prophylactic agent, we might dispense or should dispense cod liver oil, still I think we would obtain better results if we educated the colored people to increase the purchase of milk.

Dr. A. F. Hess, New York: It is well known that milk will not prevent rickets. Children who get plenty of milk get rickets. Breast fed children get rickets; among the colored it is not at all unusual to see very marked rickets among the breast fed; so that the milk is not a protection. Just what is the specific nature of the cod liver oil, I do not know. Olive oil will not take its place. It requires some animal oil, probably from some glandular organ.

In this table milk was taken forty-seven times and cocoa thirty-eight; the latter was made almost entirely with milk. We must also remember that the yolk of the egg has a very high fat content. In order to simplify matters I have omitted the milk taken with tea and coffee. I have abbreviated the study very greatly, but have calculated all according to calories and find that they take an adequate number of calories of protein, carbohydrate and fat.

CARBON MONOXID POISONING

WILLIAM D. McNALLY, A.B.
Chemist, Cook County Coroner's Laboratory
CHICAGO

The deaths from carbon monoxid poisoning in large cities now exceed those from any other poison. In Cook County our records show a steady increase in death by such asphyxiation. The total number of gas cases for 1916, 501, constitutes nearly 8 per cent. of the entire number of coroner's cases, taking fourth place in the numerical order of different forms of death for the year. The increase is to be attributed, not to carelessness or ignorance, but rather to the widespread knowledge of the ease with which carbon monoxid produces death, the more marked increase coming under the class of suicides, as shown in the accompanying tables.

Carbon monoxid occurs most commonly as a product of combustion in ordinary stoves, salamanders, furnaces, blast furnaces[1] and gas engines;[2] in fumes from explosions, and in "after damp" of explosions of methane and coal dust in mines; in mine fires, in the smoke of burning buildings, and in illuminating gas. In electric furnaces having limestone linings, the carbon dioxid is reduced to carbon monoxid by the heated electrode.[3] Tobacco smoke contains about 80 c.c. of carbon monoxid to each gram of tobacco burned.[4] Using an intermittent aspirator to imitate the smoking of tobacco, I found that the carbon monoxid of the inhaled smoke from cigarets was from 0.014 per cent. to 0.26 per cent. of the tobacco and paper consumed; from cigars it was from 0.027 to 0.15 per cent., and from pipe tobacco 0.027 per cent.

[1] Willcox: Asphyxiation from Blast Furnace Gas, Technical Paper 106, Dept. of the Interior, Bureau of Mines, Washington, D. C., 1916.

[2] Hood and Kudlich: Bulletin 74, Department of the Interior, Bureau of Mines, Washington, D. C., 1915. Analysis of exhaust gases shows them to be a mixture of carbon monoxid, carbon dioxid, oxygen, nitrogen, hydrogen, water vapor and a small but negligible quantity of gasoline vapors. The amount of carbon monoxid varies with the size of the engine cylinder, good carburation and poor carburation; the maximum amount of carbon monoxid was 13.5 per cent. in tests made with gasoline mine locomotives.. The exhaust from automobiles contains varying proportions of carbon monoxid, from 1.16 to 6.62 per cent., and has been the cause of the death of a number of people. The blood from several necropsies was submitted to me for examination. I found the hemoglobin to be 36 per cent. saturated in one case, and 40, 53 and 64 per cent. saturated in three other specimens. Cases of poisoning from carbon monoxid have been reported in France in ambulances warmed from the exhaust gases of the engine.

* Undoubtedly many of the "undetermined" cases were suicides, the evidence being inadequate to warrant a verdict of suicide.

The greatest percentage of carbon monoxid asphyxiation is through the medium of illuminating gas, which has the characteristic odor of the hydrocarbons accompanying the carbon monoxid gas. The familiar odor does not prevent many accidental poisonings, as the odor may not be perceived by those in deep sleep, or by a person with a defective sense of smell. It has been suggested that ethylene (C_2H_4), which is very poisonous to plants, might be the real cause of the gas asphyxiation.[5]

The proportion of carbon monoxid differs greatly in domestic and industrial gases, varying between 4 and 30 per cent., in coal gas 4 to 10 per cent., and 30 per cent. in water gas, and 20 and 30 per cent. in producer gas. Almost all illuminating gas contains a large proportion of water gas, so that when this gas is discharged into an inhabited space it becomes exceedingly dangerous. An atmosphere containing 0.2 per cent. is capable of destroying life.[6]

It is commonly believed that during the winter months the percentage of carbon monoxid increases, and that this is the chief reason for more deaths from gas poisoning. The percentage of carbon monoxid does not, however, increase during the winter. Table 1 gives the percentage of carbon monoxid and the number of deaths from gas asphyxiation for each month for the years from 1912 to 1916 inclusive. The more extended use of gas in the homes during the dark and cold months of the winter and the closed doors and windows, preventing proper ventilation if there are leaky pipes or loose cocks, accounts for the increased number of asphyxiations. All gas stoves, plates and heaters should be connected by metal instead of rubber. This precaution alone would save many lives each year.

TABLE 2.—TOTAL GAS ASPHYXIATION CASES FOR THE ELEVEN YEARS FROM 1905 TO 1915, INCLUSIVE *

Asphyxiation by Gas	Accidental	Undetermined	Industrial†	Water Heaters†	Suicide	Homicide	Totals
1905	59	55	...	...	83	7	204
1906	87	38	...	...	59	5	157
1907	76	61	...	...	74	1	212
1908	85	75	...	...	115	3	278
1909	102	81	...	...	107	12	302
1910	127	65	10	4	116	7	329
1911	103	66	4	7	115	2	297
1912	110	61	11	10	153	9	354
1913	118	64	...	1	163	3	379
1914	103	78	3	3	200	5	392
1915	126	93	5	17	242	6	489
1916	160	92	6	6	219	18	501
Total	1,256	827	39	48	1,616	78	3,924

* In this table, the cases are counted from December 1 to the following December 1, the fiscal year for the coroner's office.

† The industrial gas cases and those by water heaters were included with the "accidental" and "undetermined" up to the year 1910.

Carbon monoxid combines chemically with the hemoglobin of the blood to form a stable compound. According to the research of Nicloux,[7] one volume of carbon monoxid acts like 220 volumes of oxygen. The corpuscle is not dead. All it needs is oxygen under sufficient tension to displace the carbon monoxid. Hill[8] and Barcroft[9] have demonstrated that carbon monoxid combines more readily with unsaturated oxyhemoglobin than with hemoglobin. Hemoglobin will take up more carbon monoxid at a given tension if a little oxygen is present than if oxygen is completely absent. Hufner[10] found that 1 gm. of carbon monoxid hemoglobin contains 1.338 c.c. of carbon monoxid, computed at 0 C. and 760 mm. pressure. The oxygen absorbed from the air is normally taken up by the blood in the form of a loose chemical combination with the red coloring matter (hemoglobin) of the corpuscles, and in this form it is carried to the tissues in which it is used. Oxygen and carbon monoxid combine chemically with hemoglobin in equal molecular proportions, and therefore in equal volumes, the oxygen combination readily liberating its oxygen, while the carbon monoxid is relatively stable.

People nearest to the doors or windows in a room into which illuminating gas is escaping suffer the least, and those nearest the floor the most.

Case 1.—Dec. 22, 1906, E. F. and a woman went to a rooming house at 4 p. m. At 5 p. m. the landlady noticed the odor of gas coming from the room. As no one responded when she knocked at the door, entrance was gained from the transom. The man was found dead. The woman, still breathing, was removed to a hospital, where she recovered. The woman was on the inside of the bed, near a window. A gas heater was found in the room with two burners still lighted, and three unlighted burners from which gas was escaping.

Case 2.—Feb. 12, 1915, C. W. and roommate were found in a room unconscious from gas escaping from a defective hose on a gas heater. The roommate, who was nearer to a window, recovered.

Case 3.—March 16, 1916, F. M. A. died from gas escaping from a defective heater. The roommate on the inside of the bed nearer the window recovered.

Many other cases could be cited from our records, but the foregoing are typical, and the first case illustrates that a person can be asphyxiated in a room where a gas burner or jet is lighted.

LETHAL DOSE

Exposure to a contaminated atmosphere for two or three minutes may cause serious illness. Burrell[11] found that exposure for twenty minutes to air containing 0.25 per cent. of carbon monoxid made him sick for eight hours after the exposure. Air containing as little as 0.1 per cent. of carbon monoxid when breathed for several hours produced headache and vomiting with some members of the Bureau of Mines, while others were not affected. An exposure of ten minutes in a cellar has killed a person.[12] Two men in a cooper shop fire in Chicago, June 7, 1917, went into the burning building to recover their tools. In thirty minutes both were found dead. Examination of the blood showed that death was due to carbon monoxid asphyxiation (from smoldering wood).

DURATION

In the majority of cases the victims are found dead or die a short time afterward. Fishbein[13] reports a patient living five days, Long and Wicki,[14] thirty-six days, Sibelius,[15] three months. I have examined the blood of several patients who lived two days, and one who lived four days after exposure to illuminating gas. Recovery is usually complete within a week, but aftereffects may persist for weeks and months. O'Malley[16] reports a case of a woman who, poisoned by illuminating gas, did not regain her mental faculties for three months. He refers also to a case cited by Broudel, namely, that of a physician poisoned by carbon monoxid, who lost his memory, this amnesia lasting eighteen months, at the end of which time he fully recovered.

There are few references in toxicologic literature to homicidal poisons unaccompanied by simultaneous suicide by illuminating gas, or gases containing carbon monoxid.

Case 4.—Dec. 14, 1916, Mrs. B. turned on the gas, killing her two children. Her husband had committed suicide the previous day. The woman was found to be insane and was committed to an asylum.

Case 5.—June 26, 1917, a mother killed her baby with gas, attempting suicide. She was held for murder.

Carbon monoxid poisoning may be of interest in civil cases, for instance, under conditions in which death is a form of chronic poisoning and the results amount to criminal negligence on the part of another.

In another case, the estate of *Catchman Olsen* vs. *City of Chicago*,[17] the widow was given a verdict of $3,500, the death of Olsen having been proved to be due to a leaky gas-pipe in one of the repair shops of the city. When an insurance policy is involved it is of the utmost importance to show the presence of carbon monoxid by chemical examination, and to prove whether the case is a murder, a suicide or an accident, as a policy may be void in the case of a suicide. The origin of the poisonous gas may usually be found from the surroundings, as an open gas-jet, or a leak in the feed pipes. A loose-fitting stockcock of many a gas-jet may be opened by careless persons throwing their wraps over a wall gas-bracket or over the gas fixture suspended from the ceiling. Several cases of such carelessness were investigated by the coroner's office during 1916. At inquests it is frequently desirable to distinguish between poisoning by coal gas, illuminating gas, or other source. At the present time there are no good analytic methods by which we can distinguish illuminating-gas poisoning from that due to coal fumes. Wachholz[18] has suggested that the presence of hydrocyanic acid in the blood, and Cruz[19] that the presence of hydrocarbons in the blood gases would identify the source of the carbon monoxid as being illuminating gas. An investigation of the room for the source of the carbon monoxid will give more definite results than a chemical examination of the blood gases.

In one case investigated, a medical student had been overcome by carbon monoxid from a smoking oil-stove on which he was cooking his meals. The room, free from gas fixtures, was covered with soot. In three different instances a closed stovepipe damper caused the coal-gas fumes to enter the room and produce death by carbon monoxid gas.

Two or more persons may be exposed to a contaminated atmosphere; one or more may die, while the others recover.

Three young physicians in Melbourne, after playing tennis, went to bathe in a shower bath, in which the water was heated by a gas burner. Half an hour later a messenger found one dead and two unconscious.[20]

Jan. 5, 1917, three men were found unconscious in a room. One man died, the other two recovered. A stovepipe had parted from a hard coal burner, allowing the carbon monoxid to escape into the room. The blood of the man who died was 45 per cent. saturated with carbon monoxid.

[20] Lancet, London, 1911, p. 1102.

The time required to completely eliminate carbon monoxid by respirations of pure air has not been determined definitely. It varies greatly with different patients, the carbon monoxid hemoglobin apparently not being in all cases under sufficient tension with oxygen to readily liberate the carbon monoxid. Henderson[21] states that carbon monoxid is practically eliminated in three or four hours. The experiments of Michel[22] tend to show that it does not exceed a few hours; Koch[23] states that he has found it after ten hours; Pouchet[24] after sixty hours; Fishbein[13] after five days; Wachholz[25] after seven days. In specimens of blood submitted to me from two cases ending fatally in two days, and one of four days' duration, I was able to detect carbon monoxid hemoglobin. I have had over 100 cases of over four hours' standing, in which I could detect carbon monoxid by definite color tests and the palladious chlorid method. In a large number of my cases of gas poisoning, with clear histories of attempted or consummated suicide by means of illuminating gas, the blood failed to show the presence of carbon monoxid after the respiration of pure air and oxygen for a few hours. Blood from suicides who died within a half hour after being discovered in a gas-filled room contained as high as 13.5 per cent. of carbon monoxid by volume. Blood from other cases in which life was prolonged for a couple of hours contained from traces to 5.5 per cent. carbon monoxid.

The compound of carbon monoxid hemoglobin can be dissociated by hydrogen and carbon dioxid as well as with oxygen. Gaglio[26] demonstrated that carbon monoxid inhaled by an animal may be recovered from the expired air with a loss of only 2.8 per cent., due to experimental conditions. The odor of illuminating gas has frequently been noticed in the expired air of patients after being taken to a hospital. Nicloux states that he has found carbon monoxid in normal blood of dogs and in human blood. The amount found in the blood gases of dogs living in Paris varied from 0.08 to 0.18 per cent. Using the method of Fodor, I have failed to find carbon monoxid in the blood of dogs and in normal human blood. Buckmaster and Gardner[27] failed to find carbon monoxid in the blood gases of cats.

For the symptoms and pathology of carbon monoxid poisoning the reader is referred to an article by Dr. W. Gilman Thompson,[28] and an article by Dr. G. L. Apfelbach.[29]

TESTS FOR CARBON MONOXID

Carbon monoxid may be detected in the air through the absorbent power of a solution of cuprous chlorid in an excess of hydrochloric acid or an excess of ammonia.[30] With an active solution of cuprous chlorid with large amounts of carbon monoxid, from 20 to 40 per cent., the residual gas after passing through the cuprous chlorid will contain only 0.03 to 0.10 per cent. carbon monoxid.[31] Birds and mice have been used for the detection of carbon monoxid in the air of mines. With 0.2 per cent. carbon monoxid, a mouse collapsed in fifteen minutes. At the end of an hour it had lost all muscular power. It died in two hours. Canaries are more sensitive to carbon monoxid, 0.2 per cent causing distress in one and a half minutes, and they will fall from the perch in five minutes.[32]

Air may be drawn through a bottle containing iron wire gauze moistened with ammoniacal water, then through a Liebig bulb containing 10 c.c. of diluted blood (1:200). The blood may be examined by means of the spectroscope or the tannic acid reaction, Hempel being able to detect 0.06 per cent. carbon monoxid by aspirating large volumes of air through the diluted blood. Paper moistened with a 2:1,000 neutral solution of palladious chlorid, hung in a 10 liter bottle of air, will blacken if the air contains as small an amount as 0.05 part of carbon monoxid in 1,000 parts of air. The paper is also blackened by hydrogen sulphid, ozone and sulphurous acid.

Carbon monoxid hemoglobin imparts to blood a characteristic pink color, even when only a small proportion of the gas is present. Five-tenths c.c. of the unknown sample of blood and a like amount of the normal blood are diluted to 100 c.c. in a cylinder. The normal blood will have a buff yellow tint and the sample, if it contains carbon monoxid, will have a pink color. In testing for carbon monoxid in a contaminated atmosphere, a tube or cylinder containing the diluted normal blood is taken to the place where the air is to be examined. The normal blood is poured out into another tube, so that the air takes the place of the blood. The normal blood is then added to the tube, corked and shaken for about ten minutes. If the air contains carbon monoxid, a distinct pink color of the carbon monoxid hemoglobin will be noticed when the comparison is made with the original buff colored blood.

A large number of tests have been suggested for the detection of carbon monoxid hemoglobin, all of which take a number of hours before a positive result can be reported. If the blood is more than 27 per cent. saturated with carbon monoxid, the spectroscopic examination will readily show the carbon monoxid hemoglobin. If less than 5 per cent. of the coloring matter is saturated, all of the color tests will fail. For the rapid detection and estimation of carbon monoxid in the blood I have found Fodor's method to be the best. In the routine examination of blood for gas poisoning I have found the dilution test, the boiling test, the sodium hydroxid test, the basic lead acetate test, the spectroscopic examination, the palladious chlorid test, the ferrocyanid test, and the tannic acid test the most reliable. If positive results are obtained with the tannic acid, basic lead acetate, and palladious chlorid tests, all other tests can be considered superfluous.

Spectroscopic Test.—In the examination of carbon monoxid hemoglobin spectroscopically, I use a 1 per cent. solution of the blood in a small cell of 1 cm. inside diameter holding 0.5 c.c., mounted on an ordinary microscopic slide. With a Zeiss microspectroscope, a comparison with normal blood of the same dilution can be made simultaneously. Carbon monoxid hemoglobin shows a characteristic absorption spectrum closely resembling that of oxyhemoglobin, having two absorption bands between the D and E lines. When the blood is more than 27 per cent. saturated by carbon monoxid, the addition of a reducing agent, as Stokes' reagent or a solution of ammonium sulphid, does not convert the spectrum into one of reduced hemoglobin, which is a single band beginning at the D line and occupying a little more than half the space to the E line.[33]

Boiling Test.—Blood containing carbon monoxid gives a brick-red coagulum, if boiled. Ordinary blood gives a brownish black precipitate.

The Sodium Hydroxid Test of Hoppe-Seyler.—This is made by mixing blood in a porcelain dish with an equal volume of sodium hydroxid solution (of specific gravity 1.3) when normal blood forms a black, slimy mass, which appears greenish brown in thin layers, while carbon monoxid blood forms a red coagulum.

Tannic Acid Test.—The tannic acid test of Wetzel is one of the easiest and most delicate of the color tests. The blood, diluted one part by volume to four of water, is shaken with an equal volume of a 1 per cent. tannic acid solution (the original method calls for three times the volume of tannic acid solution, but I prefer an equal volume). Normal blood becomes gray in twenty-four hours, in the presence of carbon monoxid, a carmin red. The results are marked and the color distinction easy. The difference persists and becomes more marked with increasing time. The red precipitate holds its color for months. One specimen in my laboratory still retains the carmin color after four years. One per cent. of carbon monoxid (5 per cent. saturated) can be detected in blood with the tannic acid test. In an exhumed body which had been embalmed for thirty days, I was able to demonstrate the presence of carbon monoxid hemoglobin by the tannic acid and palladious chlorid methods.

Basic Lead Acetate Test.—In the basic lead acetate of Rubner, four volumes of basic lead acetate are added to one volume of carbon monoxid blood, and shaken for about one minute. Carbon monoxid gives a fine red color; normal blood gives a brownish color changing to a brownish-gray. The difference increases on standing; the red is still noticeable after many months. Formaldehyd used in embalming fluids interferes with this test, giving a whitish coagulum (Fishbein).

Potassium Ferrocyanid Test.—When 10 c.c. of blood are mixed with 15 c.c. of a 20 per cent. potassium ferrocyanid solution and 2 c.c. of a 30 per cent. acetic acid, a solid coagulum gradually results; if normal, the coagulum is dark brown to black, but when the blood contains carbon monoxid, a bright red will be obtained (Wetzel).

Haldane's[34] *Quantitative Method.*—For the carbon monoxid, this yields satisfactory results with fresh blood; but with dark colored blood from cadavers, the colors are hard to match with a Duboscq colorimeter, the results obtained being far too high compared with the palladious chlorid method.

For the quantitative estimation of carbon monoxid in air and in blood, the method of Nicloux[35] or that of Fodor[36] is preferred to that of Haldane, especially with blood from cadavers which may not be of a bright cherry red. The method of Nicloux is based on the reaction of the oxidation of carbon monoxid by iodic acid and the determination of the liberated iodin with a standard solution of thiosulphate. In a form of apparatus devised by Seidell,[37] the carbon dioxid liberated may also be determined. The reaction may be expressed by the equation: $I_2O_5+5CO=5CO_2+I_2$.

The method of Fodor, based on the reduction of palladious chlorid by carbon monoxid, is much better for the examination of carbon monoxid in blood. The reaction is expressed by the equation: $PdCl_2+CO=Pd+2HCl+CO_2$. For the examination of the blood, 5 c.c. are diluted with 20 c.c. of water in a large test tube of 80 c.c. capacity; a small piece of sodium hydroxid is then added to aid in the expulsion of carbon monoxid. A tube containing 10 c.c. of palladious chlorid precedes the tube containing the blood to remove the carbon monoxid from the laboratory air. A third U tube following the tube containing the blood contains a solution of lead acetate, and a fourth tube contains dilute sulphuric acid. The chain of tubes is completed by the addition of three U tubes containing a solution of palladious chlorid.[38] The test tube containing the blood is heated in a water bath to 90 C., while a gentle current of air, previously drawn through the tube of palladious chlorid, is conducted through the chain of tubes at the rate of 300 c.c. per hour for four hours. If carbon monoxid is present, the palladious chlorid is reduced, and a black precipitate of palladium will be deposited. The reduced palladium is collected on a filter paper, washed with water and dissolved in hot nitrohydrochloric acid. The U tubes after washing with water will have a small amount of palladium adhering to the sides. This can be dissolved in the hot nitrohydrochloric acid and added to that dissolved from the filter paper. The solution is evaporated on the hot water bath, taken up with strong hydrochloric acid three or four times to remove all traces of nitric acid. The residue is dissolved in water and titrated with a solution of potassium iodid containing 1.486 gm. to the liter. The diluted palladium chlorid solution is heated on the water bath before each addition of the potassium iodid solution. A brown precipitate of palladious iodid is filtered off and the operation is repeated until the addition of potassium iodid fails to produce a brown cloudiness. Each cubic centimeter of the potassium iodid solution represents 0.1 c.c. of carbon monoxid. In case the blood contains only a small amount of carbon monoxid, as is demonstrated by the tannic acid and other color tests, 20 c.c. of the blood are used in a small Erlenmeyer flask. When it is desired to report the saturation of the blood after obtaining the percentage of carbon monoxid by volume, one can use the relation x:20, since a saturated blood will hold in combination 20 per cent. by volume of carbon monoxid.

[38] The commercial salt is dissolved in hydrochloric acid, with the addition of nitric acid, evaporated to dryness on the waterbath, moistened with hydrochloric acid, dried, taken up with a small amount of water and again dried to free it from excess acid. The residue is then made up to volume so that 500 c.c. will contain 1 gm.

Helping the Crippled Soldier to Select an Occupation.—A great aid in helping a soldier to decide about his future is acquaintance with the records of other men with similar physical handicaps who have made good—men who have been trained and who are now holding jobs at attractive wages. In addition, such practical results lend plausibility to the expectations in prospect which are being held out to him. A difficulty, however, is found in the abnormal premium on industrial labor in war time. Even a disabled man may be able to go out and earn seven dollars a day in a munition factory. This constitutes a very potent present counter attraction to representations of moderate but permanent employment after a course of training. If he makes the opportunist choice he will, on the return of employment conditions to normal, be reduced to the status of a casual laborer, perilously near the verge of mendicancy. No pains should be spared to prevent this eventuality. Care should be taken that the representations to the man while encouraging, should in the main be accurate. Workers with the crippled soldiers should not be misled by reports of extraordinary success in isolated cases. The men will, sooner or later, learn the truth, which will tend to discredit the veracity of the vocational officials.—Douglas C. McMurtrie: The War Cripple, Columbia War Papers.

CARCINOMA OF PROSTATE

AN IMPROVED TECHNIC FOR RADICAL EXCISION WITH PRESERVATION OF URINARY CONTROL *

HUGH HAMPTON YOUNG, M.D.
BALTIMORE

In 1905, I presented a radical operation[1] for the cure of cancer of the prostate, and showed by an exhaustive study of a large number of clinical cases that the disease was far more common than usually supposed. At that time sixty-eight cases of carcinoma had been encountered in five years, during which time 250 cases of benign hypertrophy were seen, making 21 per cent. of carcinoma. Since then, there have been numerous confirmatory publications. The statistics of Oliver Smith give a proportion of 16 per cent.; of Davis, 20 per cent.; of Kummell, 20 per cent.; Pauchet, 20 per cent., and Mullin, 25 per cent. Wilson and McGrath, studying 469 specimens removed by prostatectomy at the Mayo Clinic, found that 15.5 per cent. were cancerous. These confirmatory statistics show that cancer of the prostate is a very common disease, and that it presents a serious problem to the surgeon, especially as the importance of early diagnosis and radical excision has been conclusively demonstrated.

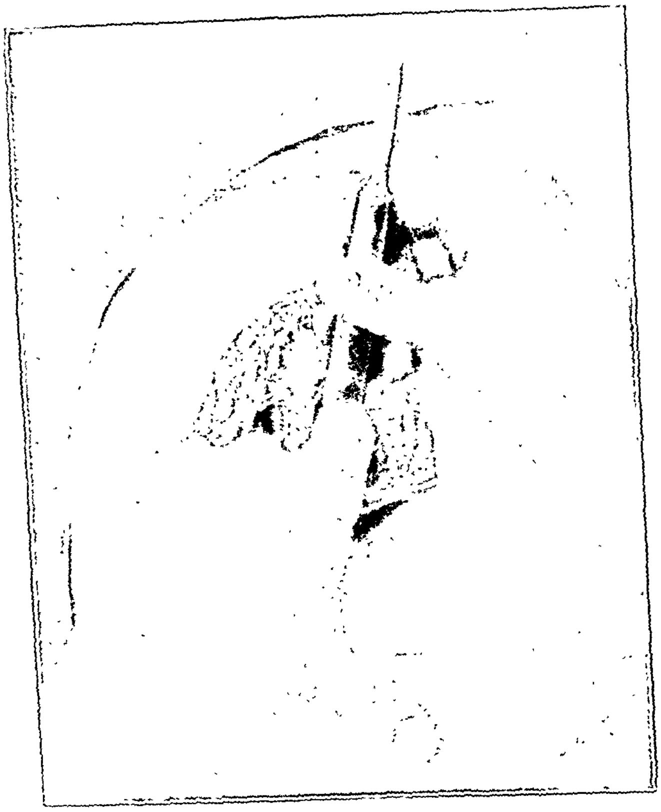

Fig. 2.—Opening up the space on each side of the central tendon by blunt dissection.

My reports of cases in which I had carried out my radical operations showed conclusively that radical cures may be obtained; but the fact that all of these patients *suffered* with incontinence during the day caused many surgeons to oppose the operation. Thus Judd, in 1913, said that he considered the incontinence an insuperable objection to the operation. During the past three years, I have greatly improved the technic of the operation, so that *now* it can be carried out without producing incontinence, thus removing the only possible objection to the procedure, which, in my opinion, is indeed a radical curative operation of great value.

The patient is placed in the exaggerated lithotomy position on the Halsted perineal board or some table giving an equally good position (and there are few that do), the penis injected with 5 per cent. argyrol for antiseptic purposes, and a No. 24 sound passed as far as the anterior portion of the prostatic urethra. The perineum is then cleaned up with tincture of iodin, towels are placed, and an inverted V perineal incision made, as in the operation for simple hypertrophy of the prostate, but a little longer on each side, as shown in Figure 1.

After the incision has been carried through the fat and subcutaneous fascia, the space on each side of the central tendon, bounded anteriorly by the transversus perinei muscle, posteriorly by the levator ani, and externally by the ischiopubic ramus, is opened up by blunt dissection, as shown by Figure 2. The bifid tractor is then introduced, and after division of the central tendon (Fig. 3) and the recto-urethralis muscle close to the bulb, the membranous urethra is exposed, incised longitudinally on the sound, and the edges of the mucous membrane picked up with non-crushing clamps, as shown in Figure 4. The prostatic tractor, Figure 5, is then introduced[2] and opened out ready to draw the prostate down into the wound. The next procedure is to divide the posterior layer of Denonvillier's fascia at the apex of the prostate on each side, thus exposing the anterior layer of Denonvillier's fascia, which forms the posterior cover-

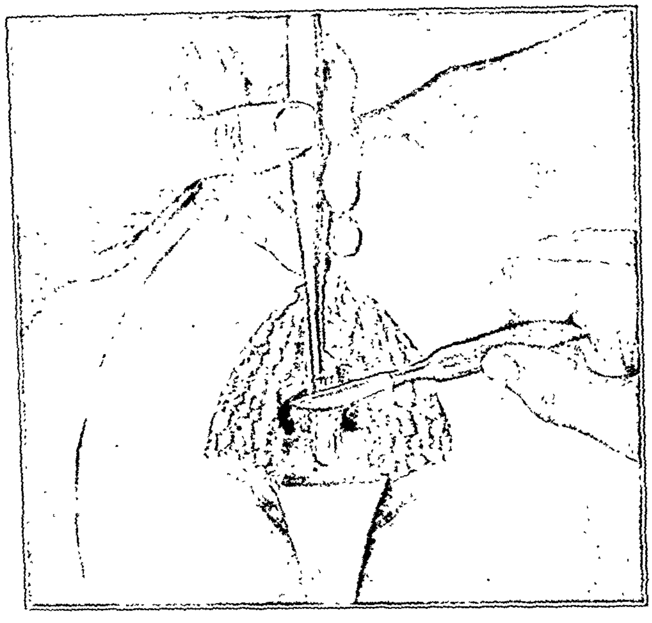

Fig. 3.—Bifid retractor inserted; division of central tendon.

* Owing to lack of space this article has been abbreviated in The Journal by omission of some of the illustrations. The complete article appears in the author's reprints.

[1] Described first in the Johns Hopkins Hospital Bulletin, 1905.

[2] Many incorrect models, much too rectangular and difficult to introduce, are on the market. The approved models, such as are shown in Figure 20, present a more tapering point, the bend is not so square and they are very easy to introduce, thus doing away with the necessity of the many modifications which have been devised.

ing of the prostate and seminal vesicles, and undoubtedly has much to do with the prevention of carcinoma of the prostate and seminal vesicles from traveling backward toward the rectum and adjacent structures. Passing upward between these two layers of Denonvillier's fascia, the posterior surface of the prostate and seminal vesicles is freed, after which the lateral surfaces of the prostate are exposed by blunt dissection, the operator taking care to keep within the anterolateral prostatic fascia, separating it from the prostate. The great plexus of blood vessels, and the important nerves of the perineum lie in front of this fascia so that by stripping it up from the prostate, it is easy to avoid hemorrhage and not only preserve the vascular supply, but also the perineal nerves, including that of the external sphincter. The modification of my operation which I have adopted during the past three years, and which has done away with incontinence, consists in respecting this anterolateral fascia, and passing between it and the lateral and anterior aspect of the prostate, as indicated by the dotted line in Figure 6.

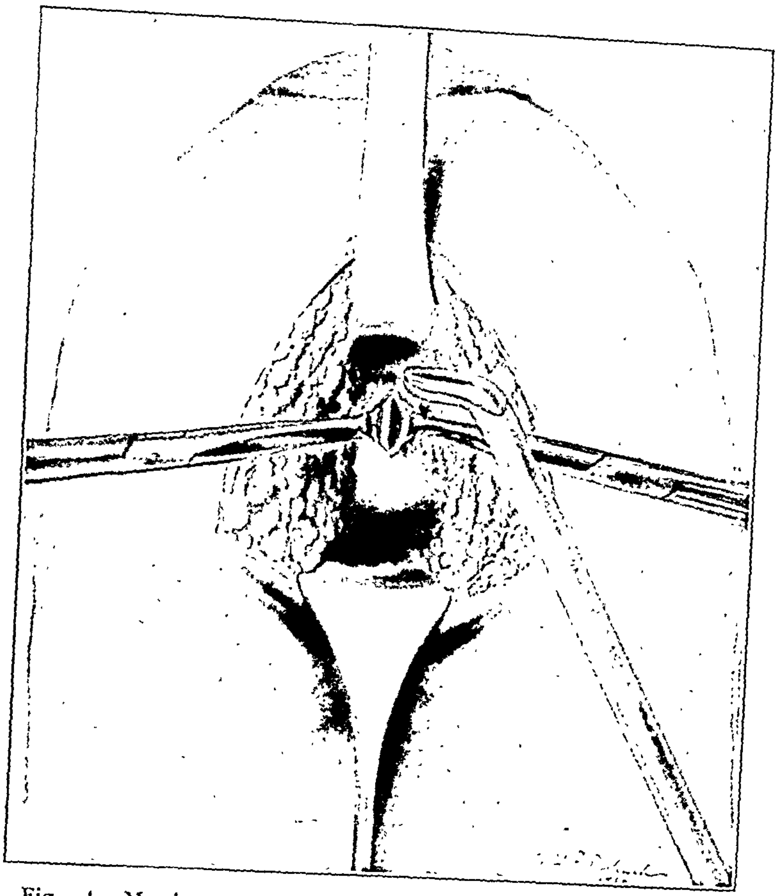

Fig. 4.—Membranous urethra exposed, incised longitudinally on sound, and edges picked up with *noncrushing* mucosa clamps; prostatic tractor ready for insertion.

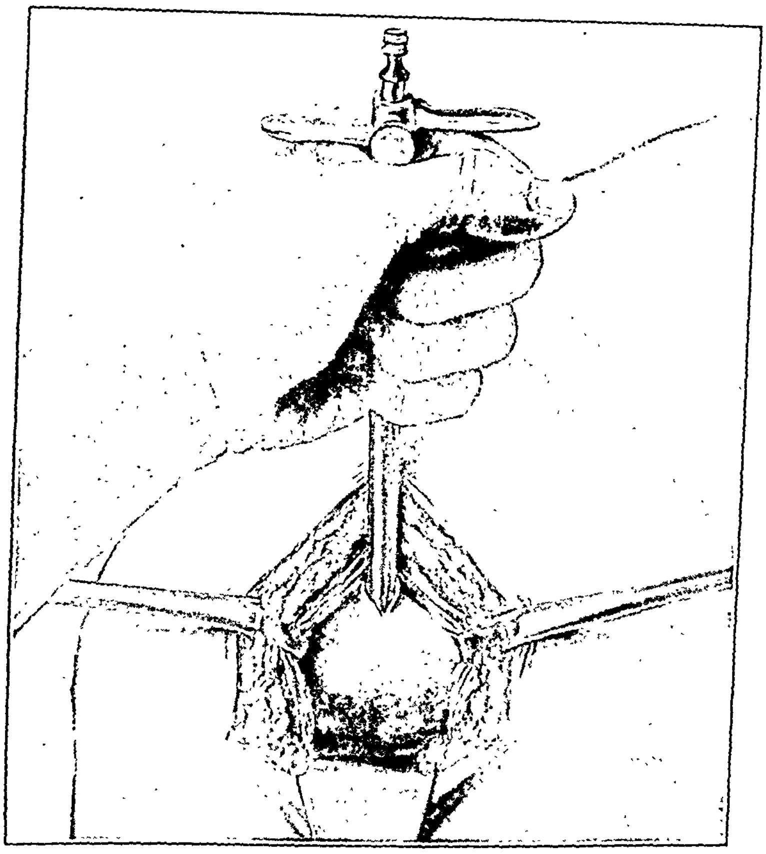

Fig. 5.—Tractor has been inserted and opened; posterior surface of prostate exposed showing anterior layer of fascia of Denonvillier.

After this fascia has been freed by blunt and sharp dissection on each side, the next step is to divide the membranous urethra just in front of the prostatic tractor, as shown in Figure 7, the operator again being careful to keep beneath the anterolateral prostatic fascia, which is readily stripped up, exposing the anterior surface of the prostate until the prostatovesical juncture is reached, as shown in Figure 8. During this procedure the prostate, freed laterally, posteriorly and anteriorly, is gradually drawn outward, bringing the bladder well down toward the operator, who then plunges a scalpel through the bladder wall close to the upper limit of the prostate and enlarges the opening into the bladder by scissors on each side, thus exposing the interior of the bladder, and particularly the trigon, as shown in Figures 8, 9 and 10. The dotted line here indicates the next step, namely, the curved incision across the trigon, which passes about 1 cm. below the ureteral orifices on each side and includes the mucosa, submucosa and muscle (Fig. 11). The bladder is then pushed upward, as shown in Figure 12, thus exposing the tissues covering the anterior surfaces of the seminal vesicles and vasa

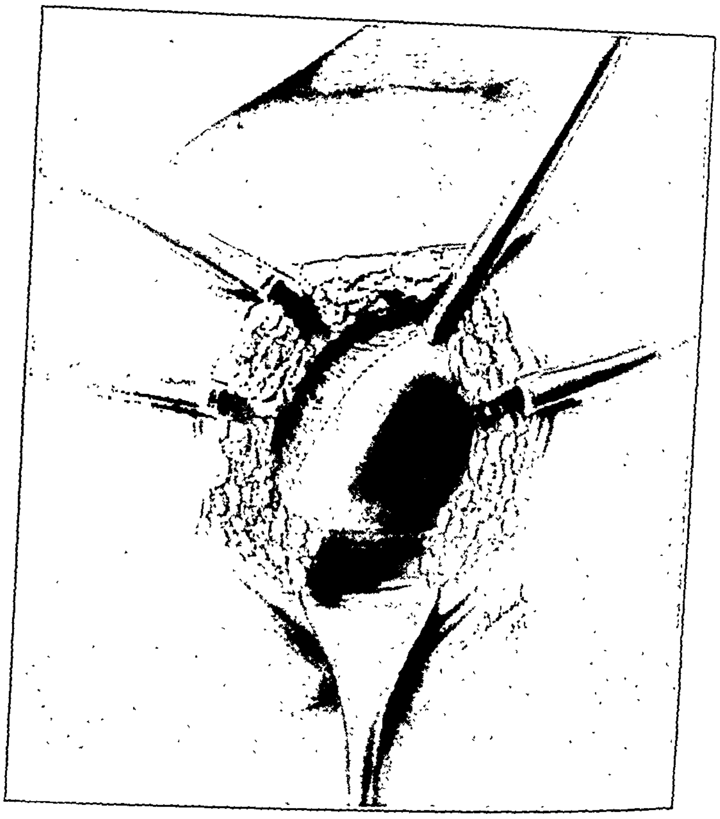

Fig. 6.—Dotted line shows where dissection should proceed in order that the operator keep between the anterolateral fascia and lateral aspect of prostate.

deferentia, which become more and more exposed as the blunt dissection proceeds (Fig. 13). The operator avoids going too close to the seminal vesicles and vasa deferentia, freeing these structures *en masse*, and ligating the fascia containing the blood supply at the upper end of the seminal vesicles on each side, as far distant above the prostate as possible. The vas deferens is then isolated, freed well above the tip of the seminal vesicle, drawn down, clamped and divided. The same procedure is repeated on the other side, thus freeing the carcinomatous mass, which is removed in one piece, composed of the entire prostate with its capsule, and urethra, a small portion of the membranous urethra, a cuff of the bladder, including most of the trigon, both seminal vesicles and 6 or 7 cm. of the vasa deferentia, with intervening and surrounding tissues. The mass removed is shown in Figures 21, 22 and 23, which are taken from the actual operative specimens.

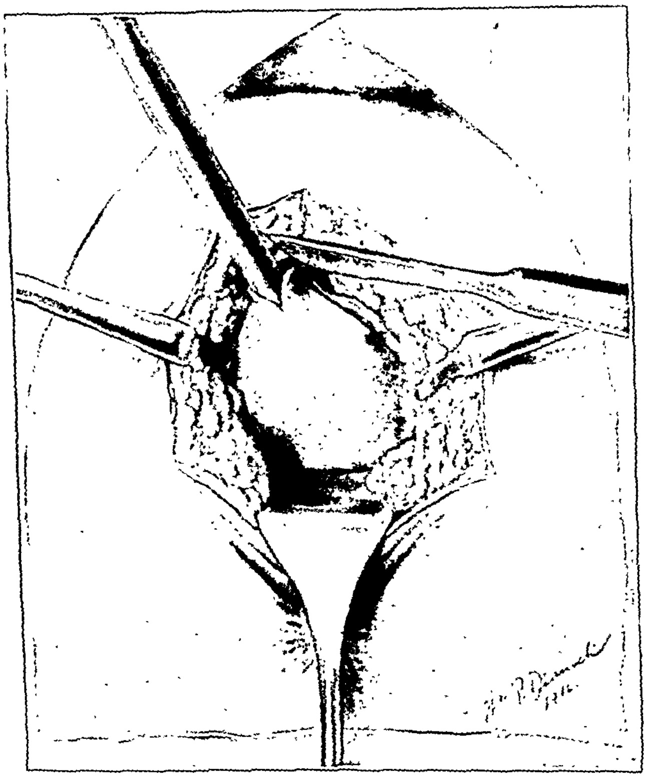

Fig. 7.—Division of membranous urethra.

The problem next confronting the operator is to draw down the bladder and form an anastomosis between it and the stump of the membranous urethra at the triangular ligament. The vesical opening is usually about 3 inches in diameter, and about 3 inches distant from the urethra to which the bladder is to be sutured; but by grasping the anterior wall and drawing it downward, no difficulty is experienced in performing the anastomosis, as shown in Figure 14. The sutures are interrupted and of chromic catgut tied externally and including both mucous membrane and muscle. As a rule, about ten such stitches are required, but no difficulty is experienced in obtaining an excellent anastomosis around the small retained urethral catheter, as shown in Figure 15. There remains then a longitudinal opening in the bladder which is easily closed by continuous chromic catgut suture, as shown in Figures 16 and 17. In performing the anastomosis, I have recently used my new boomerang needle holder (Fig. 24), and have found it very efficient, particularly for deep work. The rest of the operation consists in placing a small iodoform gauze drain behind the line of sutures, drawing the levator muscles together with chromic catgut (Fig. 18), and closing the skin with a continuous subcuticular chromic catgut suture, as shown in Fig. 19. The catheter is fastened to the glans penis with adhe-

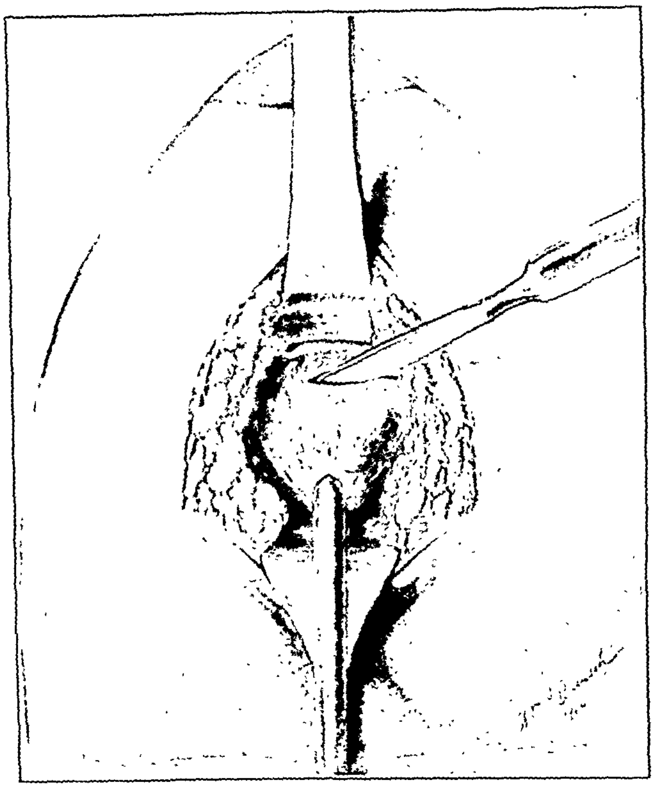

Fig. 8.—Entire prostate turned down and the bladder wall incised transversely just above upper limits of the prostate.

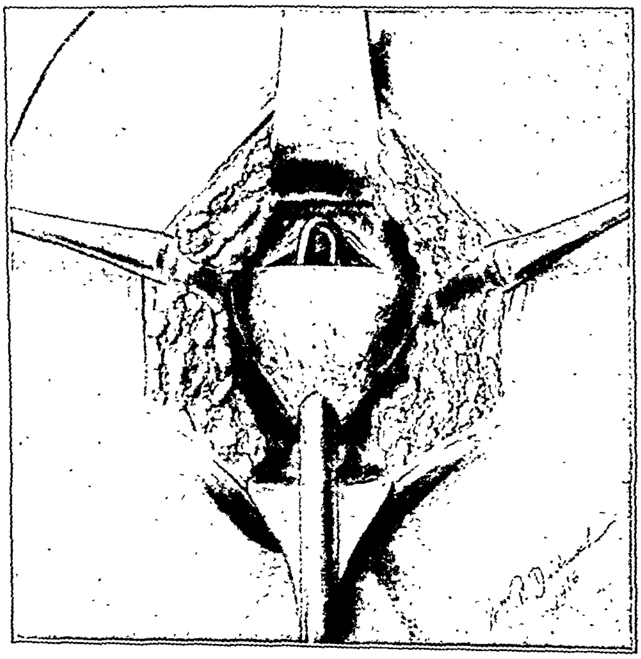

Fig. 9.—Blade of tractor protruding through incision in bladder wall.

sive plaster and a subcutaneous infusion given at the end of the operation (before if advisable). By preserving the anterolateral prostatic fascia, and thus avoiding hemorrhage from the plexus of Santorini, and by carefully clamping and ligating bleeding points when the bladder is divided and the seminal vesicles freed from deep adhesions, pronounced hemorrhage is avoided, and the operation is practically free from danger and is not exceedingly difficult.

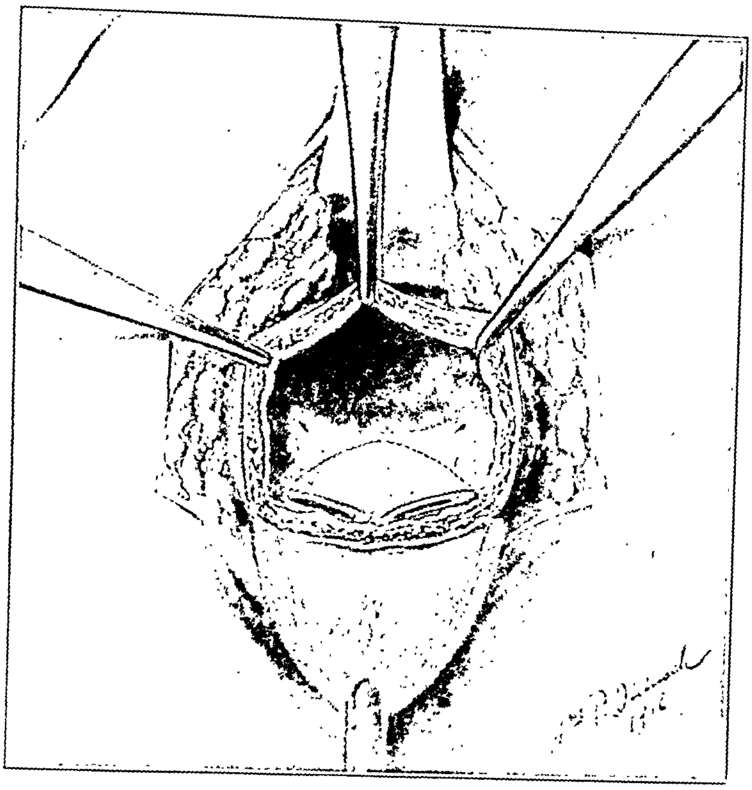

Fig. 10.—Bladder incision enlarged: Dotted line indicates course of completed incision, passing across trigon about 1 cm. in front of ureteral orifices.

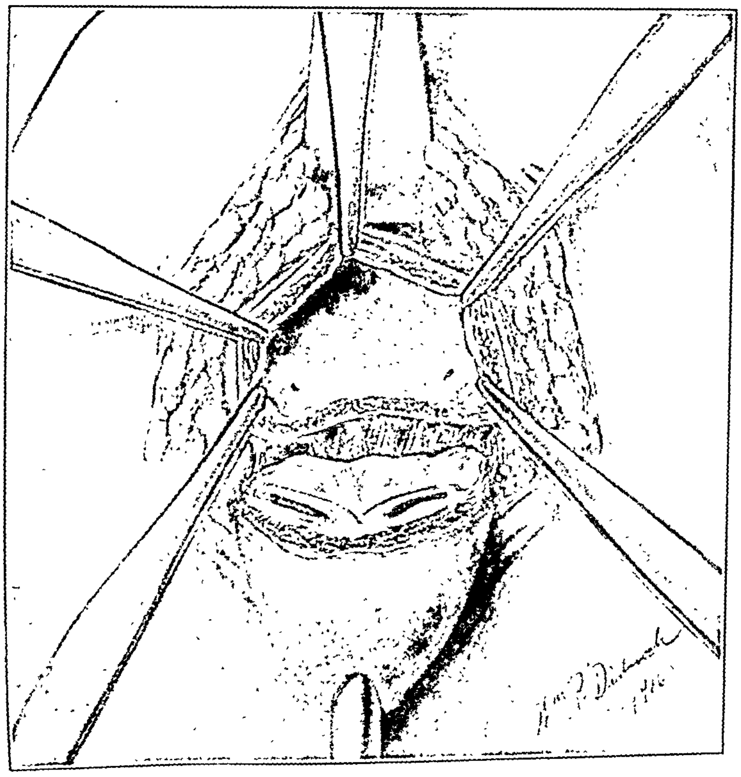

Fig. 11.—Incision in bladder wall completed, the prostate now being attached only by the seminal vesicles and vasa.

AFTER-TREATMENT

The treatment during the convalescence is very similar to that employed after perineal prostatectomy, namely, water in abundance, subcutaneously if necessary, hexamethylenamin, and daily irrigation of the bladder with small amounts of boric acid solution through the retained urethral catheter, which is allowed to remain in place eight or nine days. The gauze packs are removed in two or three days, and no further packing is introduced. In nearly all cases there is leakage for a week or so, but in almost all cases the wound heals completely within the course of a month, and no cases of permanent urinary fistulas have resulted.

My experience in thirteen cases shows that it is not necessary or even advisable to pass sounds or other urethral instruments, as stricture does not occur at the point of anastomosis, and dilations are therefore unnecessary.

RESULTS

In the first eight cases there was incontinence when the patient was on his feet, and more or less constant dribbling; but when the patient was in a recumbent posture, and particularly when in bed, there was usually no incontinence and the bed was not wet, interval urination of fairly normal character occurring at this time. One patient died of shock immediately after the operation. In the last four cases in which the perfected technic described in the foregoing was carried out, incontinence has not been present, and some of these patients are able to retain urine as long as six or seven hours, they void freely without difficulty, have excellent sphincteric control, and have practically normal urination. One patient, operated on over three years ago, is able to sleep all night undisturbed, and voids large amounts of urine at infrequent intervals and in a normal manner. The other cases are more recent, but give evidence of just as satisfactory results.

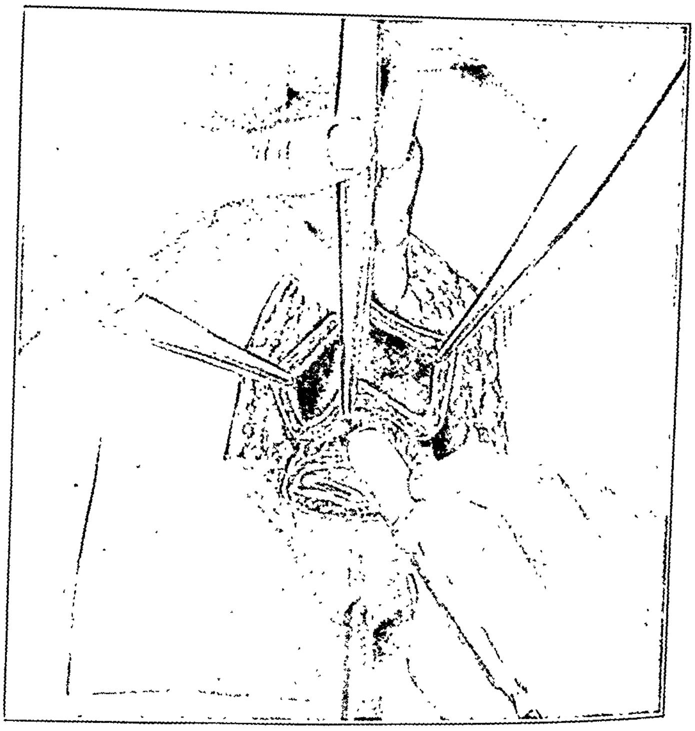

Fig. 12.—Freeing vesicles and vasa surrounding tissues from posterior aspect of bladder wall.

Success in obtaining urinary control after this extensive radical procedure is undoubtedly due to the new scheme of carefully preserving the anterolateral prostatic fascia, and thus avoiding injury of the nerve and blood vessels which lie in front of it and which supply the triangular ligament and external sphincter with vascularity and innervation.

Nevertheless, it is interesting to note that normal micturition can exist even when the entire prostate, with the prostatic urethra, membranous urethra and almost all of the trigon and cuff of the bladder are removed, and the defect restored by plastic anastomosis between the bladder and the stump of the membranous urethra. It is also interesting to note that the external sphincter is able to functionate sufficiently to prevent incontinence, even when the other sphincteric structures of the prostate and bladder have been removed.

At the operation, the lower ends of both ureters were intentionally excised for a short distance in Case 2, the operator thinking that the disease had reached this point. This was a mistake, as it was found afterward that the induration was inflammatory in character. In Case 5 the lower end of the left ureter was involved, and had to be excised. This patient died of shock, and necropsy revealed that, while the seminal vesicles were free, the disease had traveled into the peritoneal cavity. The cystoscopic evidence of elevation of the whole trigon should evidently militate against the radical operation, as shown by this case. In Case 3, the lower end of the left ureter was unintentionally divided with scissors when the division along the left lateral wall of the bladder was made. Anastomosis was made high up, and no inconvenience resulted. (The patient lived three years). In nine cases, the operation was carried out with apparent success and without shock, but a study of the specimen removed showed carcinoma near the upper limit in two patients (Cases 1 and 3).

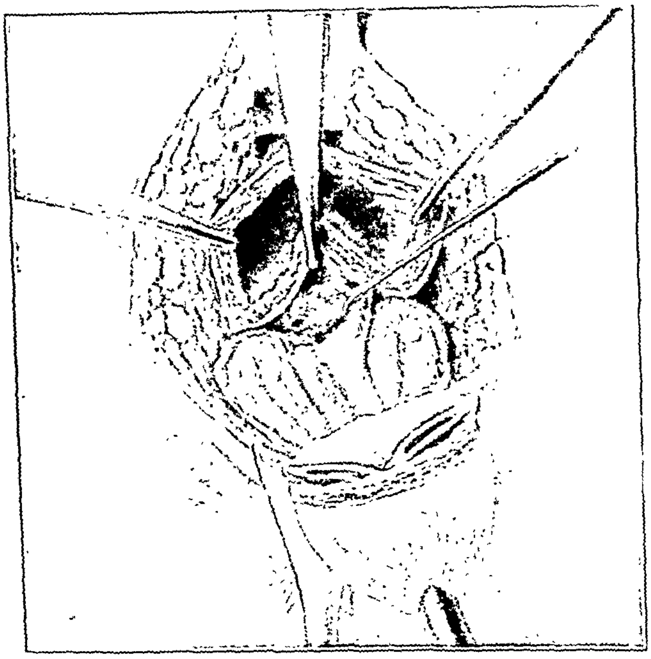

Fig. 13.—Freeing of upper limit of seminal vesicles; vascular adhesions in this region have been clamped and ligated; division of vas.

In Case 2, the patient died nine months after the operation as a result of traumatism and infection, caused by an attempt to remove a stone adherent to a silk suture. Necropsy revealed a very small area of recurrence, 1 cm. in diameter, back of the bladder. In Case 3, the patient lived over three years in comfort, but necropsy revealed metastases in various parts of the body, the bladder and urethra, however, being free from recurrence. In Case 1, in which the patient died six weeks after the operation from ascending renal infection, as a result of the intentional but injudicious division of the two ureters, extremely careful examination of all the pelvic tissues at necropsy, with numerous sections taken for microscopic study, failed to reveal any evidence of carci-

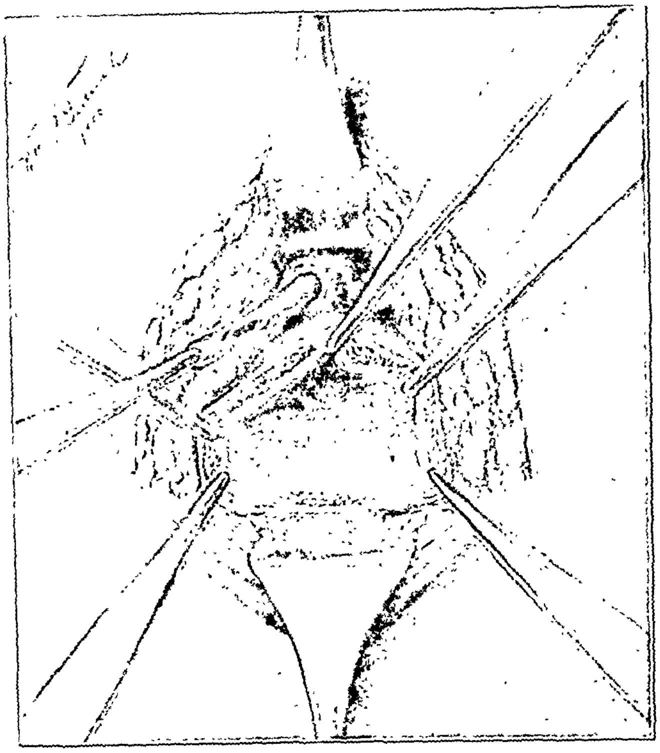

Fig. 14.—Catheter inserted in urethra preparatory to urethrovesical anastomosis.

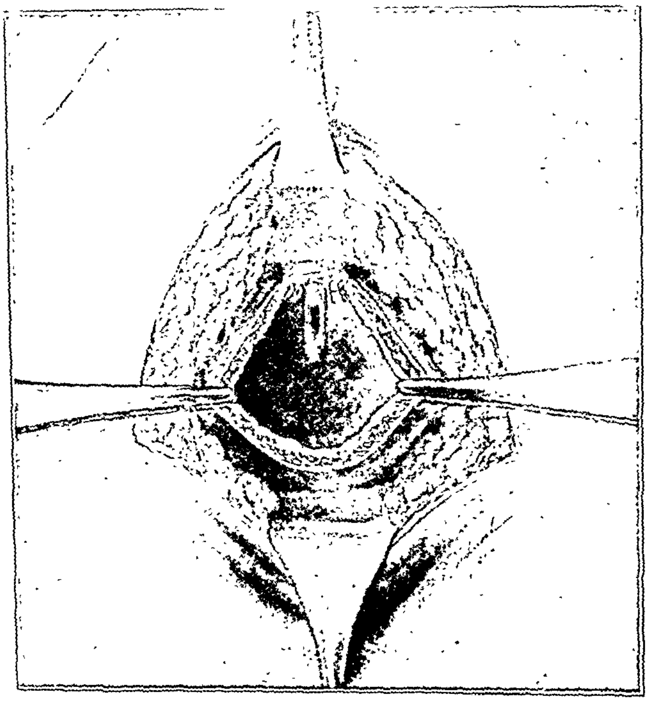

Fig. 15.—Beginning of anastomosis; sutures are of interrupted chromic catgut, tied externally.

noma, and it seems probable that the disease had been completely eradicated. Five patients have apparently been cured. One patient died from angina six and a half years after the operation, and necropsy revealed no recurrence of the cancer. Another patient is well five and a half years after the operation. In both of these cases the operative specimens disclosed that the disease had not reached the upper line of excision. Three patients operated on two and a half years ago are alive and apparently well. Two cases in which operation was performed within the past month are so recent that the ultimate result is not known, although the prospects are excellent.

In Case 2, there was incontinence when the patient was on his feet, but when in bed and in a sitting posture there was fair control. In more recent operations control has been much better; in Case 9, there was hardly any incontinence, and in Cases 10, 11 and 12, no incontinence at all occurred; the patients voided naturally with normal force, and only three or four times by day and none at night. In Case 13, the patient is still in the hospital. This improvement in the prevention of urinary incontinence has been accomplished by using great care to elevate the anterior layer of the pelvic fascia, which encloses the lateral and anterior aspects of the prostate, with the nerves and blood vessels of that region. This not only obviates hemorrhage, but preserves the vascular and nervous supply of the triangular ligament and external sphincter, and thus prevents incontinence. It removes the one objection to the operation.

As a result of the experience gained in these thirteen cases, it may be said that the operation should not be attempted when the carcinomatous infiltration extends more than a short distance beneath the trigon (as determined by the cystoscopic examination with the finger in the rectum and the cystoscope in the urethra), or when the upper portions of both seminal vesicles are involved, or in cases in which there is an extensive intervesicular mass and indurated lymphatics or glands, or when involvement of the membranous urethra or muscle of the rectum shows that the disease has manifestly progressed too far.

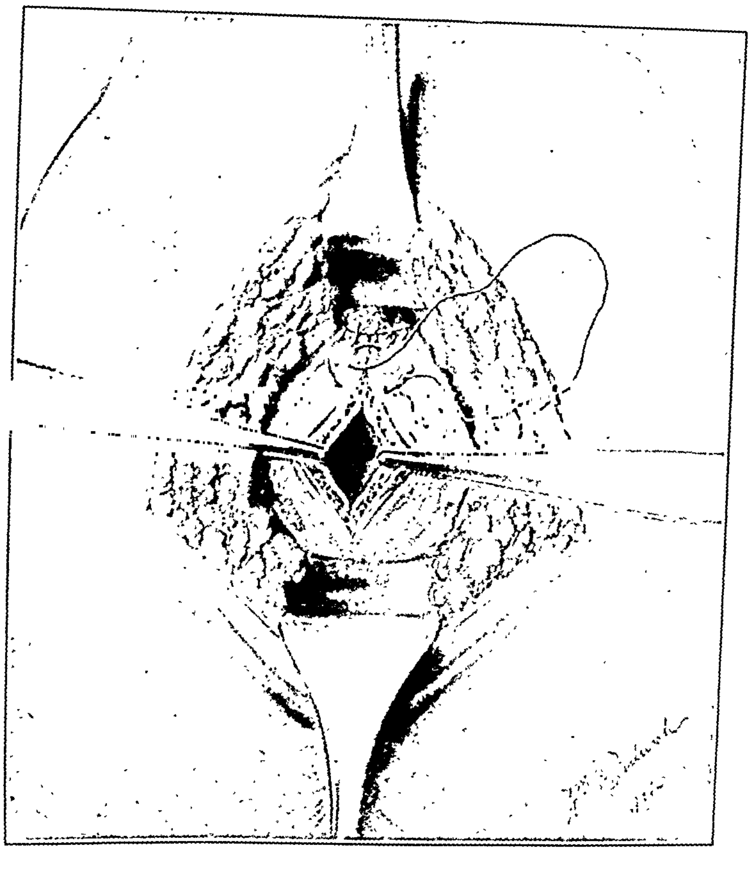

Fig. 16.—Closure of remainder of vesical incision longitudinally, with a continuous suture.

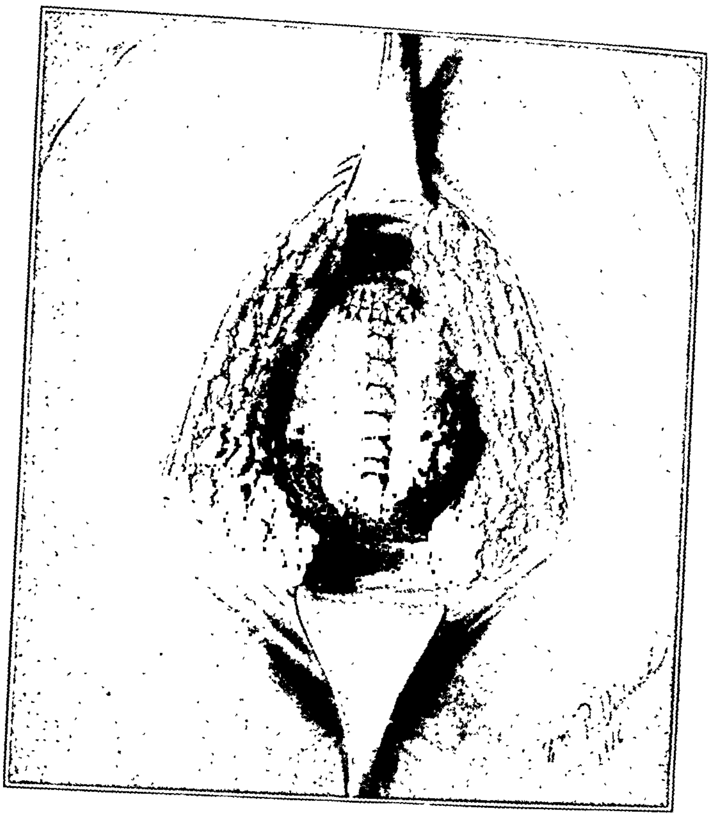

Fig. 17.—The anastomosis completed.

Further, it may be said that the corners of the trigon containing the ureteral papillae should be left intact with sufficient tissue below them to enable proper suturing and to leave their openings free from constriction, 1 cm. above the wound; that the hemorrhage should be carefully checked (by hugging the capsule, injury of the periprostatic plexus being avoided); that silk should never be used to hold the tissues together in making the urethrovesical anastomosis; that when the operation is attempted early it can be performed without much danger or great difficulty, and with excellent chance of cure; that only seven of the ten cases recorded in this paper were suitable for the radical operation, and that in all of these the disease was apparently completely removed. It seems probable that radical cures have been obtained in at least five cases. Only two with definite recurrence have been found.

Radical Cures by Partial Prostatectomies.—In two cases, in which small nodules of cancer were completely removed in the course of perineal prostatectomy for supposed benign hypertrophy, there has been radical cure for eight and fifteen years, and therefore they deserve to be mentioned.

Subtotal Radical Excision of Carcinoma.—This operation is employed with a view to the conservation of the sphincters, and most of the urethra and capsule. The operation has been carried out in six cases. The first case showed a well circumscribed area of carcinoma in the right half of the posterior capsule of the prostate. The lateral lobe lay in front of this and showed an adenomatous hypertrophy, which was also present in the left and median lobes of the prostate. The area was so well circumscribed that I did not perform the typical radical operation, but contented myself with removal of the right half of the prostate with its capsule, the right lateral wall and floor of the urethra, and the suburethral tissues with ejaculatory ducts and lower portion of the right seminal vesicle and vas deferens, all in one piece. The left lateral and median lobes were then excised as usual, the roof, left lateral wall of the urethra and vesical sphincter being preserved.

The result was splendid. The perineal fistula closed on the ninth day, and the patient was discharged on the fourteenth day. The report by letter five years later said: "entirely well, urination normal."

Four other patients have been operated on by a similar technic, also with excellent results, now four years in one case, and the method can be recommended in cases in which a small nodule of carcinoma well circumscribed and surrounded by healthy tissue is present. Great care must be exercised, however, in choosing cases, and the radical operation is generally the safer to employ.

Typical Conservative (Partial) Prostatectomy.—In seventy-five cases, this operation was done, with no idea of radical cure, but merely to remove the obstruction to urination. In two cases, however, a small nodule of carcinoma was completely excised in the removal of the lateral lobes.

In many cases (65 per cent.) the results in removing obstruction have been just as satisfactory as in benign cases, the patient generally having a good functional result as long as he lives.

Radium.—In the last two years we have used radium very effectively in cases of advanced cancer of the prostate and seminal vesicles, combining it with the use of perineal prostatectomy or the punch operation in case obstruction persisted, with some excellent functional results. Radium unquestionably has marvelous effect in reducing the carcinomatous infiltration of the prostate by the new methods which I have presented,[3] but the cases reported are as yet too recent to permit claims of absolute cures. We have, however, in radium an agent of undoubtedly great potency and value in urology.

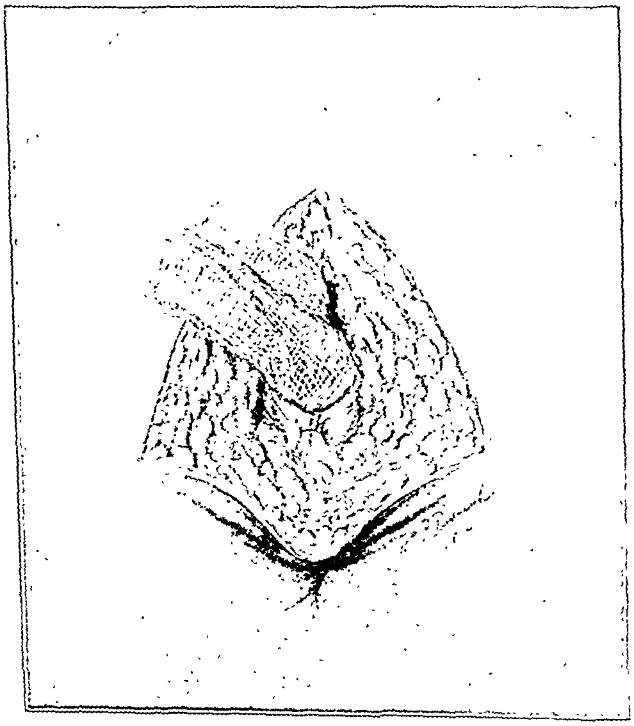

Fig. 18.—Gauze drainage passing down to site of anastomosis, one suture bringing together fibers of levator ani.

CONCLUSIONS

1. Early diagnoses are imperatively needed.
2. The radical operation is a very satisfactory surgical procedure.

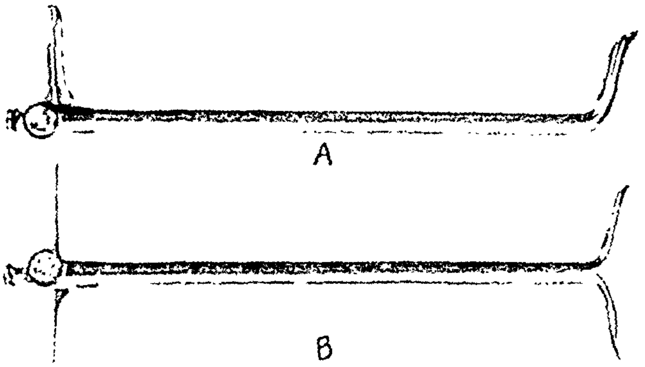

Fig. 20.—*A*, prostatic tractor closed, before insertion into membranous urethra; *B*, prostatic tractor opened after entering bladder.

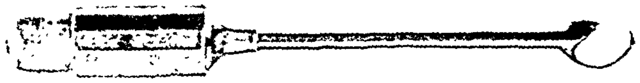

Fig. 24.—Boomerang needleholder.

3. Excellent functional results may be obtained by preserving the anterolateral prostatic fascia and the blood vessels and nerves above it, as shown in my new technic.
4. Radical cures have probably been obtained in over 60 per cent. of the cases, even though some were decidedly unpromising. Marked induration should always be suspected even when occupying only a small area, and early radical cure carried out if the disease proves to be cancer.

Suicides in New York City.—More suicide in New York City since the outbreak of the European War in 1914, illuminating gas the most frequent method, infrequent use of firearms by women committing suicide, a decrease in the use of poison as a means of ending life, these are some of the interesting facts disclosed by a statistical study of suicides in New York City. Perhaps the one fact that stands out most prominently in the accompanying tables is the greater frequency of suicide among men than women; about three times as many men commit suicide as women. Does this indicate a greater feeling of responsibility on the part of men, a greater bravery on the part of women, bravery which enables them to bear the trials and disappointments of life with greater fortitude? Considered in conjunction with the fact that during periods of financial depression suicides are more frequent, indicating that financial reverses are the most common cause of suicide, the conclusion seems justified that the incidence of suicide is greater among males because on men usually falls the worry of financial reverses. The entrance of women into business and the professions, thus bringing them a fuller share of financial responsibility, should, if this be the chief determining factor, increase the female rate, and it will be interesting, as years go by, to note the effect of changing conditions on the incidence of suicide among females.—S. W. Wynne, M.D., *Monthly Bulletin*, New York Department of Health.

THE ETIOLOGY OF PERTHES' DISEASE

PERCY WILLARD ROBERTS, M.D.
Associate Professor of Orthopedic Surgery, Post-Graduate Hospital;
Associate Attending Orthopedist, Mount Sinai Hospital;
Assistant Surgeon, Hospital for Ruptured
and Crippled
NEW YORK

The etiology of osteochondritis of the hip, generally known as Perthes' disease, has been the subject of much speculation ever since the condition was recognized as a clinical entity several years ago. Traumatism, obscure infection and perverted metabolism have each had their advocates. Tuberculosis has been eliminated because the joints recover with good function, and syphilis has been excluded because Wassermann reactions have been negative.

Notwithstanding the results of laboratory tests, I desire to advance the opinion that this affection of the hip, which occurs with considerable frequency in children, is the result of inherited syphilis.

In the course of an extensive study of orthopedic conditions produced by congenital syphilis, involving the treatment of about two hundred cases of various types, several well developed instances of Perthes' disease have come under observation. Two of them presented symptoms of unusual spasm and limitation of motion, one having acute pain on any attempt at passive movement. The symptoms in these two cases cleared up very rapidly under mixed treatment, and the other patients showed improvement in their general condition rather more quickly than would be expected without medication.

While the course of five or six cases under antispecific treatment proves nothing very definite, there are several arguments to be offered in favor of the syphilitic origin of these lesions. First, the negative Wassermann must be disposed of, and that is not difficult, for it is common experience that subjects with frankly syphilitic bone lesions, when a family history of syphilis exists and when the pathologic process disappears under mixed treatment, give a negative Wassermann reaction. Several cases of this kind have been observed during my recent studies. Therefore, it may be contended that a negative Wassermann reaction in Perthes' disease does not exclude syphilis. Secondly, the pathologic findings described by Perthes coincide with one of the most common expressions of bone syphilis in children, namely, osteochondritis. Although the joint lesions of congenital syphilis have been much neglected, every author who has written on syphilis of the bones and joints has referred to osteochondritis as it appears in the region of the knees, wrists and ankles. As a matter of fact, many cases of joint enlargement ascribed to rickets are nothing more nor less than syphilitic osteochondritis.

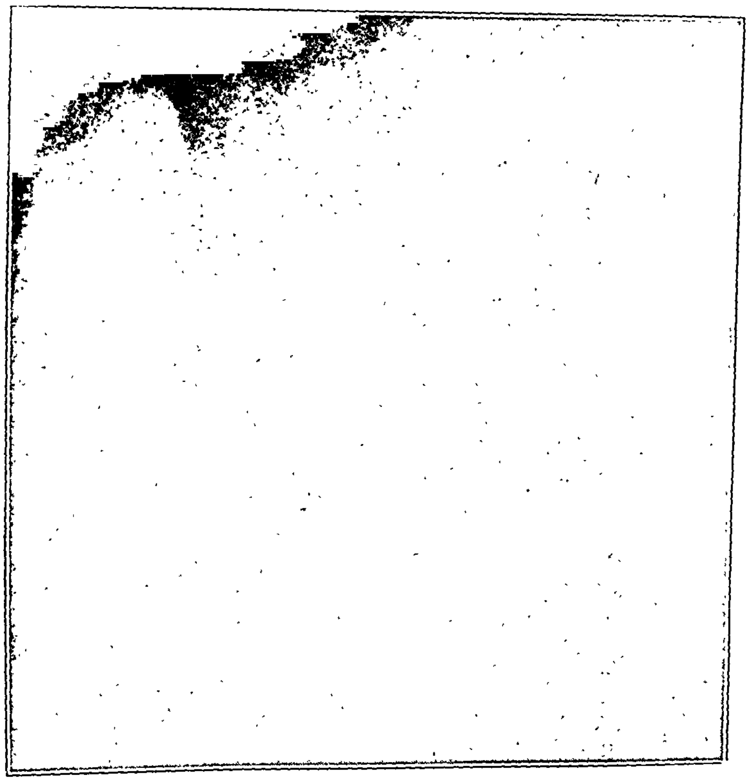

Fig. 1.—Perthes' disease. In this patient the acute symptoms that had persisted for over two years in spite of immobilization cleared up rapidly under mixed treatment without fixation.

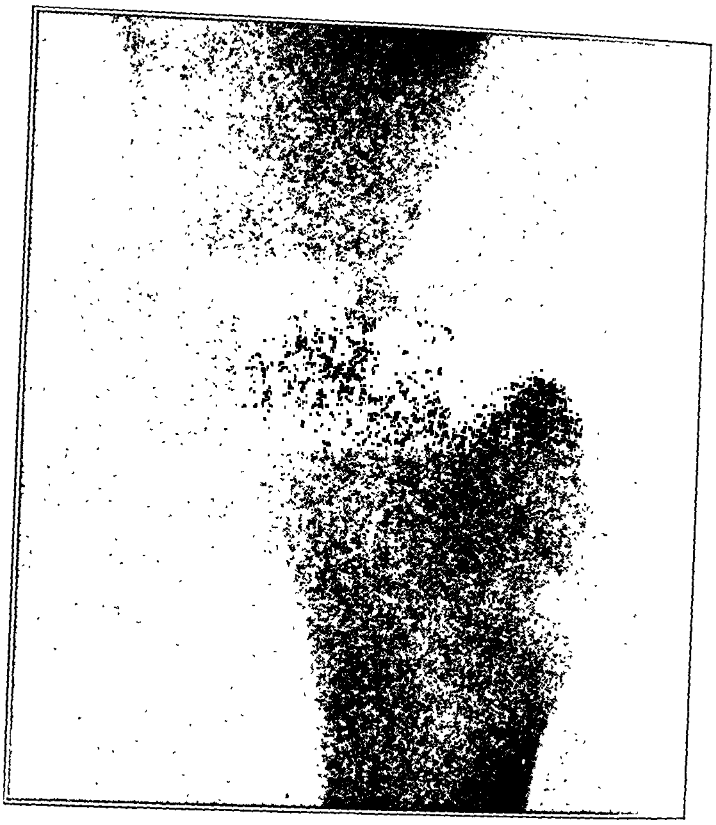

Fig. 2.—Perthes' disease. Acute pain and limited motion had been present for a year and three months, and under mixed treatment the condition disappeared within ten weeks.

Then again we find in subjects with Perthes' disease dental evidence of inherited syphilis. This does not mean hutchinsonian teeth necessarily, but more frequently the erosions and malformations of the first permanent molars and other units that have been so well described by Cavallaro, or anomalies of spacing of the incisors, to which I recently called attention.[1] These dental signs indicate that spirochetes were undoubtedly present in the body during the period of gestation, and it is a reasonable conclusion that they may have persisted to cause the condition known as Perthes' disease, just as they may persist to cause other forms of bone lesions in children.

Finally, the course of osteochondritis of the hip is similar to that of many other syphilitic joint conditions in that the destructive process is self limited and that there is a tendency to more or less complete restoration of function.

In view of the foregoing facts it would appear that treatment of Perthes' disease on the hypothesis that it is of syphilitic origin is worthy of further investigation, and it is for the purpose of stimulating interest in the subject that this argument is presented. In the writer's experience all syphilitic bone and joint conditions improve more rapidly when the dose of potassium iodid is carried to the point of tolerance than when dependence is placed on a routine dose of moderate size, and it is suggested that this technic be used when medication is adopted.

---

[1] Roberts, P. W.: New York Med. Jour., 11, 1917.

To illustrate the effect of mixed treatment, the histories of two cases under observation on the service of Dr. H. L. Taylor, at the Hospital for Ruptured and Crippled, are appended with roentenograms that confirm the diagnosis.

REPORT OF CASES

Case 1.—The patient, Ida G., aged 8 years, was suffering pain and limped in July, 1914. Night cries were noted at that time. She was treated at two different clinics for tuberculosis of the right hip. The limb was placed in a plaster cast for a year and four months. The plaster cast was then removed for a month. Pain, restlessness at night, restriction of motion and spasm reappeared and another plaster spica was applied at the Hospital for Ruptured and Crippled, Dec. 1, 1915. This treatment was continued until March 21, 1917, when the patient came under my observation. The plaster cast was removed; the hip was found to be stiff and extremely sensitive. The teeth indicated congenital syphilis, and the child was therefore placed on mixed treatment and the spica fixation discontinued. Two weeks later the patient reported for examination. Pain and spasm had disappeared. There was free rotation and considerable flexion without discomfort. From that date there has never been any return of pain. Improvement has continued, and on Oct. 1, 1917, there was flexion of the thigh to 45 degrees inside of a right angle; free rotation; no limp, and the child was extremely active. The roentgen-ray findings were typical of Perthes' disease (Fig. 1).

Case 2.—The patient, Elsie G., aged 11 years, complained, in February, 1916, of pain in the right leg; the patient limped, and tired easily. She came under observation, May 2, 1917. There was flexion of the thigh to a right angle and full extension, but rotation in extension was limited. Rotation in flexion was blocked and abduction was extremely limited. Pain and spasm occurred on attempt to force motions and there was a marked limp in walking. The teeth indicated congenital syphilis, and the patient was put on mixed treatment without any protection to the hip. A month later there was flexion to 45 degrees inside of a right angle and some rotation with the thigh flexed. There was no pain, and the child was much more active and felt better. July 18, 1917, there was almost normal flexion and free rotation with thigh flexed. There was no pain and no limp. The roentgenograms revealed typical Perthes' disease (Fig. 2).

In Case 2 the symptoms had existed a year and three months and disappeared under suitable medication in ten weeks.

576 Fifth Avenue.

Quadricentennial of Dodoneus.—The *Nederlandsch Tijdschrift voor Geneeskunde* of June 30 was devoted entirely to historical sketches of Rembertus Dodoneus, a great physician and botanist of the sixteenth century. His works include the "Cosmographia," "History of Plants," "Praxis Medica" and the "Cruydt-boeck," in which he contributed much to the materia medica of western and northern Europe which had been neglected by previous writers. He was offered the post of body physician to the king of Spain, as successor to Vesalius, but declined. Later he accepted a similar position with the emperor of Austria until he was called to the chair of clinical medicine at the University of Leyden.

SYSTEMATIZATION OF A SURGICAL SERVICE

EUGENE H. POOL, M.D.
AND
FREDERICK W. BANCROFT, M.D.
Attending Surgeon and Associate Attending Surgeon, respectively, New York Hospital
NEW YORK

In modern industrial organization, the highest degree of efficiency is attainable only by intense systematization. In hospital management the interdependence of efficiency and systematization should be recognized. Yet, this conception has been slowly grasped, reluctantly accepted, and compromisingly adopted by the medical profession. Although a mechanical and inelastic system is not suggested for the care of the sick, the advantages of a systematic plan of service, so far as this is consistent with the development and application of medical skill, are striking.

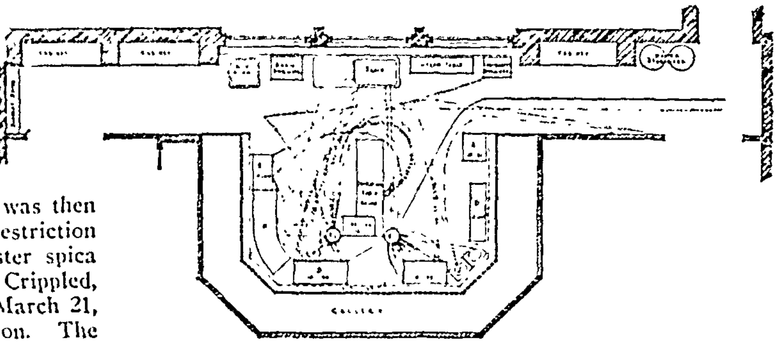

Fig. 1.—Movements of nurses during an operation for appendicitis: *N-1*, head instrument nurse; *N-2*, sponge nurse; dotted lines indicate steps taken by nurses during the operation; lines without arrows indicate "round trips," those with arrows indicate "one way trips."

Until a few years ago, hospital services were relatively small, diagnostic methods simple, the staffs small, and the turnover slow. Consequently the details were simple, comparatively few, and readily kept in mind. The treatment of the individual patient was, in general, conscientious and satisfactory.

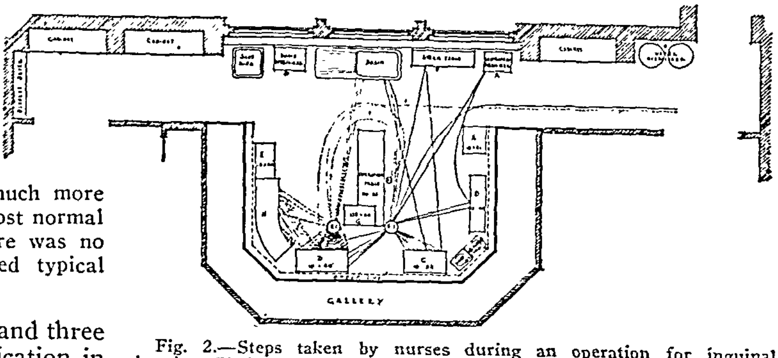

Fig. 2.—Steps taken by nurses during an operation for inguinal hernia. Similar in plan to Figure 1.

With the large service of the present day, however, the complicated methods of diagnosis, the large staffs and the rapid turnover, systematization has become essential. By means of it, the time and the energy of the staff are conserved; moreover, other things being equal, thoroughness in the study and treatment of each case is better insured, and oversights and mistakes are less in proportion to the degree of systematization.

The essentials for systematization are supervision by a permanent director and specialization in details by other members of the staff. Our service has been developed with these objects in view.

The surgical department of the New York Hospital consists of two independent divisions. They are similar in organization. We are to consider, however, only the second surgical division.

The staff of the division consists of an attending surgeon, senior associate surgeon, junior associate surgeon and assistant surgeon. Gradation is important in that it eliminates questions of authority and prerogative.

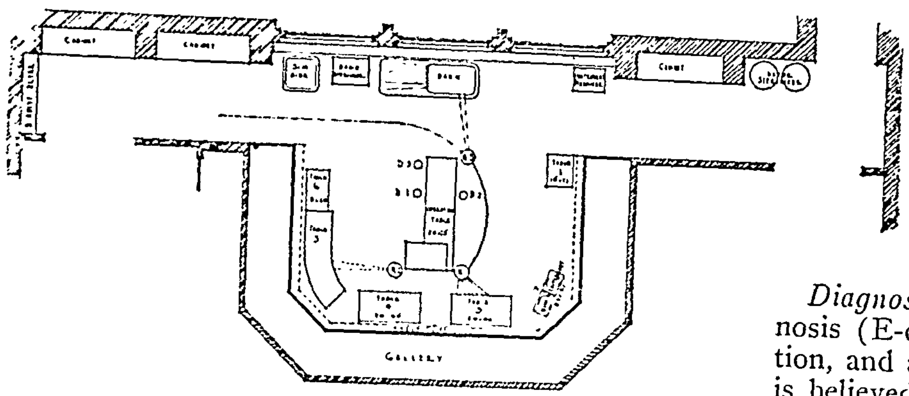

Fig. 3.—Marked reduction in movements and labor of nurses due to the introduction of simplified methods in the operating room. New and larger tables installed. Diagram was made during an operation for appendicitis.

The attending surgeon is in charge and is responsible continuously. The two associates, while equal in rank so far as hospital appointment is concerned, are graded for work on the division. When the attending surgeon is absent, the senior associate takes his place; the junior associate assumes the work of the senior, and the assistant acts as junior associate. Under this plan, the policy of the division is unvarying, because in the absence of the attending surgeon, the routine and regulations are enforced by the associate, who acts in his stead and not independently. A concerted and unchanging policy is thus possible. But such a plan demands the subordination of the individual to the welfare of the service; associates and assistants must serve the hospital as members of a team rather than as individuals.

Inspection rounds, followed by conference with free discussion, are held once a week, and a follow up or end-result system has been established. This routine furnishes the chief with an accurate knowledge of the work of the division, unifies the ideas of the staff, develops a harmonious spirit among them, and checks the immediate and late results.

The weekly inspection rounds are conducted by the attending surgeon, with the staff and student clerks. Practically every case is dressed, the treatment of the wounds is discussed, and permanent records of the condition of each patient and wound are made on the bedside charts. Following the rounds, there is a conference which is attended by the entire staff, including attending surgeons and interns. The conference embraces:

1. A review of the work of the past week, which includes: (*a*) operative results; (*b*) diagnostic errors, and (*c*) late results.
2. Report of standing staff committees (outpatient department, student clerks, follow up system, operating room technic, clinical records, etc.).
3. Reports on special subjects assigned by the chief to a staff member; or a review of the literature bearing on some unusual case on the service.

We will consider these topics in detail.

Operative Results.—Unfavorable results and unfavorable developments are analyzed: (1) deaths; (2) infections, and (3) other postoperative complications, such as hematomas and pneumonias. An effort is made to determine the cause of each unsatisfactory development. As advised by Codman, the poor results are tabulated into:

1. Errors due to lack of technical knowledge or skill (E-s).
2. Errors due to lack of surgical judgment (E-j).
3. Errors due to lack of diagnostic skill (E-d).
4. The patient's enfeebled condition (P-d).
5. The patient's unconquerable disease (P-d).
6. The patient's refusal of treatment (P-r).
7. The calamities of surgery, or those accidents and complications over which we have no control.

Diagnostic Record of the Week.—Errors of diagnosis (E-d) are referred to the operator for explanation, and a general discussion of the case follows. It is believed that such an analysis and discussion leads to greater care in arriving at a correct and exact diagnosis before operation, emphasizes the causes of diagnostic errors, and suggests means for avoiding them.

To obtain an exact diagnostic record, we employ the following method: The anesthetist, before the beginning of each operation, notes the anteoperative diagnosis on the anesthesia chart. The operator is entitled to record his diagnosis up to the time of making his initial incision; after that it cannot be changed. At the end of the operation, a revised diagnosis is recorded.

In cases in which the diagnosis at the close of the operation is still in doubt, as in certain tumors, and in some cases presenting abdominal symptoms in which no lesion has been found, final decision as to the diagnosis is deferred until it is determined by the pathologist's report or by the course of the case.

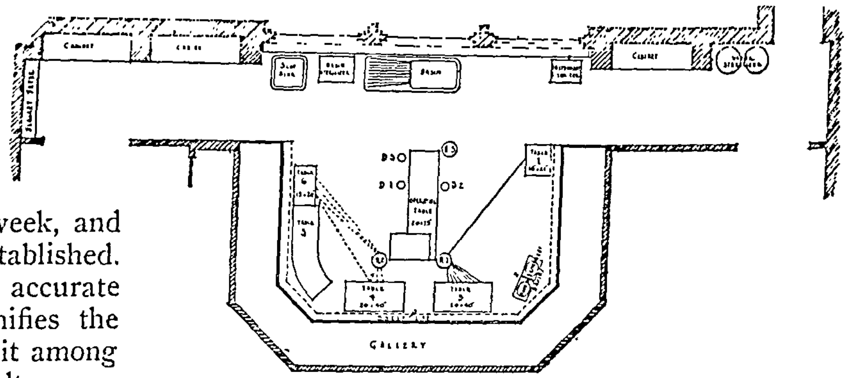

Fig. 4.—Similar in plan to Figure 3. By the elimination of unnecessary steps, the work has been greatly simplified. Diagram was made during an operation for inguinal hernia.

End-Results.[1]—The late results in the cases which have been examined on the previous Sunday morning are analyzed. Those recorded as "fair" and "poor" are discussed, and, if necessary, the original histories of the cases are reviewed. The causes of failures are sought, and measures for avoiding similar failures are considered. The errors or failures are grouped according to the classification described under operative results.

---

[1] The details of our end-result system have been described by Bancroft, F. W.: Bull. Johns Hopkins Hosp., 1916, 27, 201.

A brief comment on the end-result system is appropriate. The conscientious management of a surgical service demands not only a detailed knowledge of the immediate results of operative treatment, but also the ultimate or end-results. The operative policy of a surgical service is directly dependent on the study and analysis of the late results of operations. If it is found that a certain procedure is not giving permanent relief, the members of the staff will be stimulated to devise means that will improve the results. For example: During the two years in which this system has been in use, it has been found that a certain number of patients operated on for chronic appendicitis have not been relieved of their complaint. Certain members of the staff are now making a careful analysis of all cases diagnosed as chronic appendicitis, with the object of determining wherein lies the fault. Such a study can be made effective only by careful analysis of the end-results of a large series of cases in conjunction with the histories, physical examinations, laboratory data, roentgen-ray records, and operative findings.

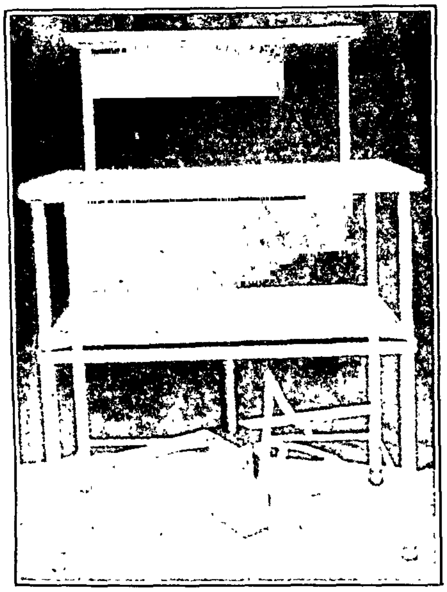

Fig. 5.—New supply table with foot pump. Elevation is used when patient is in the Trendelenburg position. Two tables are in use in the operating room, one each for the instrument nurse and the gauze supply nurse.

A follow up system, to be effective, must be so planned that all patients leaving the hospital are followed for at least one year, and selected patients for a longer period.

All patients on leaving the wards are requested to return for observation at the end of three months; if examination at that time indicates that there is no need for earlier observation, they are requested to report again at the end of nine months. We have been able to obtain the late results in approximately 90 per cent. of our cases.

We cannot emphasize too strongly the credit due to Codman of Boston for initiating the follow up system and bringing the profession to an appreciation of its importance; also to Corscaden of the Presbyterian Hospital, New York, for his extremely efficient method of putting the follow up system into effect. We employ his card system with slight modifications.

Attempts have been made to arrange the work in the wards in such a manner that the maximum attention may be given the patients with the minimum waste of effort. Complete rounds are made daily by one of the staff. Each member of the attending staff has definite days on which he makes morning rounds on all the cases on the division. Patients in the wards are considered as belonging to the division and not to individual members of the staff. In other words, if one of the attending staff refers a case to the service, the patient becomes a ward of the division. Thus, each patient has the advantage of study by the entire staff. No hardship is involved, because no fees are collected for ward patients, except workmen's compensation cases, and the fees for these are collected jointly for the needs of the division.

There is a rule of the division that the operator must examine all patients on the afternoon preceding operation. This, therefore, necessitates the visiting of the hospital every afternoon by one member of the staff.

Three difficulties are often encountered in large surgical services:

1. Delay in ordering and making appropriate laboratory and clinical examinations.

2. Delay in calling the attention of the attending surgeon to very ill patients.

3. Premature dismissal from bed and hospital of patients who have been operated on by the zealous house surgeon who wishes to make room for patients who are to undergo operation.

To overcome these difficulties the following methods have been adopted:

1. An associate has been placed in charge of each ward. It is his duty to visit his ward daily and to see all the patients who are to be operated on, order roentgen-ray and laboratory examinations as indicated, direct and expedite history taking and physical examinations, and note on the chart his diagnosis and suggestions as to treatment. He also supervises the postoperative therapy.

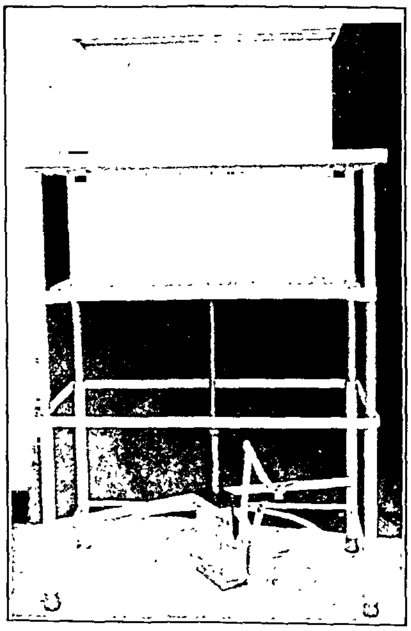

Fig. 6.—Same table as shown in Figure 5, which has been elevated for the Trendelenburg position.

2. A day book is kept on the nurses' desk, with three columns for names: In the first column are noted those patients who have not been operated on;

in the second, patients not doing well or requiring investigation, and in the third column, the names of patients presumably ready for discharge. The attending surgeon can thus learn at a glance the salient facts.

3. Each patient before going home is examined by one of the associates, who writes a discharge note on the chart. This record includes a statement as to the general condition of the patient and the condition of the wound, and a brief summary of the postoperative course. The associate gives the patient a note to the family physician or to the dispensary. In this he describes the operation and convalescence, and suggests treatment. If he considers the patient unable to leave the hospital, he instructs the nurse to keep the patient until further notice. Consequently, it is seldom that patients leave the hospital too soon or in improper condition.

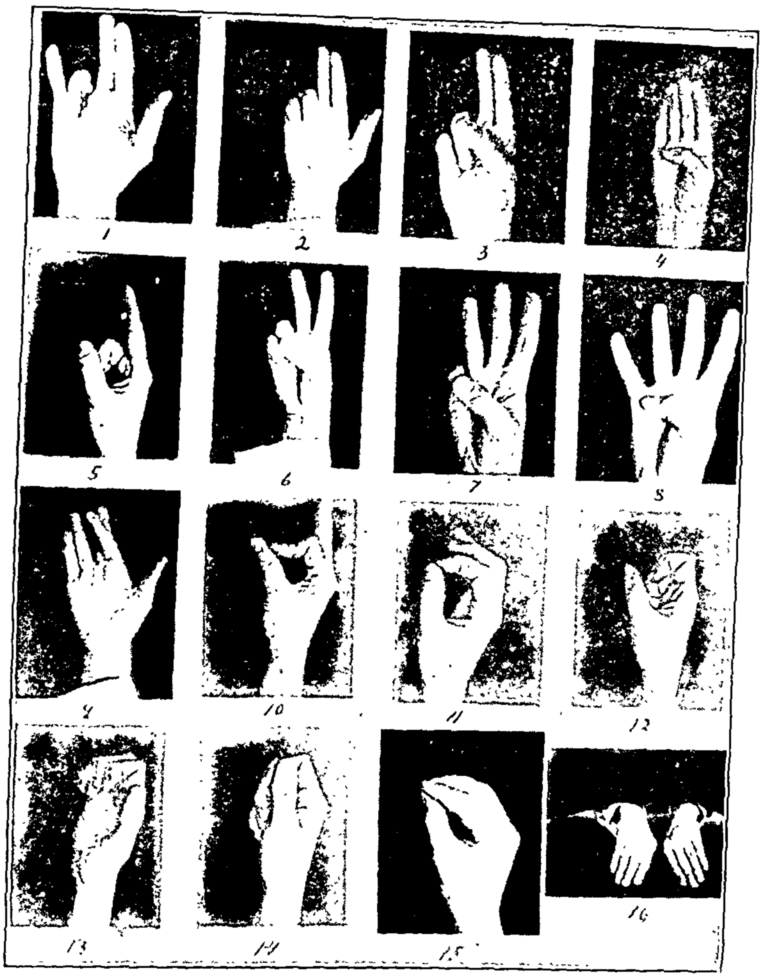

Fig. 7.—Manual signal system for use during operations: 1 *a*, artery clamp; *b*, Allis clamp (intestinal forceps); as artery clamp with wriggling of little finger; *c*, Kocher clamp, as artery clamp with wriggling of thumb; 2 *a*, Towel clip; *b*, Kelly clamp; as towel clip plus wriggling of thumb; 3, ligature; 4, sponge pads; 5, *a*, scalpel, with cutting motion; *b*, straight needle, with rotary motion; 6, *a*, thumb forceps; *b*, scissors, opening and closing fingers; 7, tissue forceps, one and two teeth; 8, tissue forceps, many teeth; 9, sharp retractors; 10, palm down: *a*, large right angle retractors, thumb and index finger; *b*, medium right angled retractors; use middle finger instead of index finger; *c*, small right angled retractors, use ring finger instead of index finger; 11, palm up: *a*, large string pad, thumb and index finger; *b*, medium string pad, thumb and middle finger; *c*, small string pad, thumb and ring finger; 12, *a*, McBurney, small; *b*, McBurney, large; use both index and middle fingers; 13, abdominal retractors; 14, *a*, aneurysm, rotary motion; *b*, cautery, squeezing motion; 15, palm down: *a*, large sponge stick, sponging motion; *b*, curved needle, rotary motion; *c*, small sponge stick, as 15 *a*, but with palm up; 16, towel, spreading motion.

OPERATIVE TECHNIC

An effort has been made to simplify the work in the operating room. The properly trained operating staff should be a well-balanced machine; it is, however, difficult to attain this end. In the average hospital, each member of the attending staff has his individual ideas as to the arrangement of the operating room and of instruments, etc. It often becomes necessary to arrange the room and to plan certain details even of routine operations differently for each man. The lack of uniformity interferes with a fixed policy, leads to confusion, and imposes a greater burden on the helpers. All routine operations should be standardized: the arrangement of the room should be uniform; a given number of instruments should be on the tray, and the same suture materials and instruments should be used. As far as possible, the same incision and procedure should be employed, but unfortunately the vagaries of the human body and the uncertainties of diagnosis require occasional deviations. However, it is possible in most cases to follow a regular system.

The staff, at the conference, decides on the routine types of operation. Let us take inguinal hernia, as an example: The modified Bassini operation with transplantation of the cord has been adopted; all members of the division use this method; all use the same instruments, sutures and needles. If a member of the staff disapproves the method or of any detail, he must present his criticisms and suggestions at a regular weekly conference.

The chief often assigns the study of a certain type of operation to a member of the staff, who presents his report at a subsequent conference. Discussions at these meetings are often very instructive.

We are making constant efforts to secure simplicity and a safe routine in the operating room. When the effort to systematize this service was begun two years ago, we felt that there was much waste of effort in the operating room work and that certain features of the work were glaringly inefficient. Let us illustrate with one detail: the steps taken by the nurses during an ordinary operation by reason of improper planning and thoughtless arrangement of the necessities for an operation. It was decided to make notes of the steps taken by all concerned during an operation. To accomplish this, one of us (Bancroft) dictated to a stenographer the movements of the various nurses and physicians during a routine operation performed by the attending surgeon (Pool). Two operations, the repair of an inguinal hernia and an appendectomy for chronic appendicitis, were thus recorded.

We made a ground floor chart of the operating room, drawn to scale with the tables in place for the operations. On this, the movements of each nurse from the beginning to the end of the operations were outlined (Figs. 1 and 2). After analysis of the dictated records and the graphic charts, we found the main faults to be:

1. Lack of system.
2. Too many and too small tables for sterile supplies, extra instruments, etc.
3. Unnecessary energy wasted when the patient is in the Trendelenburg position by nurses stepping down from benches to obtain supplies from tables and stepping up again to reach the operative field or instrument tray.

To correct these faults, we explained to the operating room staff the significance of the charts, and impressed on them the importance of simplifying the work. By interesting the nursing staff, we have been able to cut down the unnecessary steps to an astonishing degree, as is evident by reference to Figures 3 and 4.

Three of the old tables were discarded and two new ones (Figs. 5 and 6) were substituted. These are much larger than the old ones, and are provided with a foot pump so that they can be raised or lowered easily. Raising these tables to the proper level eliminates the necessity for the nurse to move from the bench in order to obtain extra supplies during pelvic operations. The stimulus to improve the technic of the routine operations keeps the staff on the alert and counteracts the monotony of the routine cases.

We have adopted a signal system (Fig. 7) for use during operations. Many others, notably Brewer, have adopted such a procedure more or less extensively, and we refer to it merely as a suggestion to those who have not had the idea called to their attention. The habit of signaling becomes automatic, and the appropriate instrument is quickly obtained. The method seems to add to the smoothness of the operation.

COOPERATION WITH DISPENSARY

An effort has been made to bring the dispensary and the hospital service into close association. The fourth man on the service is chief of the dispensary, and his privileges in the wards are dependent on his management of the dispensary. Each of the other three members of the staff is expected to visit the dispensary on a definite day each week; his visit is scheduled for a certain time, and unusual cases are reserved for his inspection and advice.

About once a fortnight, a member of the dispensary staff gives a clinic. Invitation cards are sent to the physicians of the neighborhood, and unusual cases or new methods of therapy are presented. This stimulates interest and prevents initiative being obliterated by routine.

The history of every case sent from the dispensary to the wards accompanies the patient and is attached to the ward history. On discharge, a note is written by the house surgeon summarizing the operation, pathologic findings and convalescence. The dispensary history is then returned to the outpatient department. In this manner, it is possible for the outpatient surgeon to follow his cases.

Ventilation of Shipholds After Fumigation.—Experiments by the officers of the Public Health Service in the fumigation of ships for the killing of rats suspected of being the source of plague have shown that sulphur dioxid and hydrocyanic acid gas are the best fumigants. The latter is most efficient and desirable because it takes less time, and the ship may be put into service sooner after fumigation. To shorten the time still further and render the ventilation of the ship's compartments more complete, experiments were conducted. Grubbs of the Public Health Service describes in *Public Health Reports*, Oct. 19, 1917, the methods employed. In India, according to Heiser, the gas is aspirated from the vessel through the pipes used to fill the holds with the gas. This method was not employed by Grubbs. Electric fans were placed in the vessels and operated by the electric plant belonging to the vessel. It was found that the time of ventilating the ships could be shortened, but there were objections on account of handling the wires connected with the fans. A gasoline-driven air propeller, designed to propel boats and sleds, was then employed. This was found to deliver about 22,700 cubic feet of air a minute. This fan was used for distributing the gas in the hold and also for ventilation. In its use for the latter purpose, it was attached to the hatch combing and the air introduced into the hold through muslin chutes. It was found that this machine in ten minutes would throw into the bottom of the hold an amount of air equal to the cubic capacity of the ship. This fan has been modified so that it will work horizontally, and is arranged on a frame so that it may be carried by two men. It weighs less than 100 pounds. It has been found expeditious and satisfactory.

SURGICAL TREATMENT OF CHRONIC ENTEROCOLONIC DIARRHEA*

SAMUEL C. GANT, M.D., LL.D.
Professor of Diseases of the Colon, Rectum and Anus, New York Post-Graduate Medical School and Hospital
NEW YORK

Chronic diarrhea can be temporarily relieved by rest, strict diet, antiseptic, astringent and antiperistaltic drugs and irrigation through the anus, but often recurs when the patient returns to business, eats normally and discontinues medication.

Chronic inflammation or ulceration of the intestine, however produced, is often difficult to cure except by surgical intervention. By operation and irrigation, I have permanently cured many diarrhea patients who had been previously treated for months or years by nonsurgical measures.

Up-to-date physicians and surgeons realize that removal or direct treatment of bowel lesions is essential to the successful handling of many types of chronic diarrhea; and I hold that the time has arrived for the profession to give "intestinal stasis" a rest and to devote its attention to the operative treatment of otherwise incurable chronic diarrhea.

The family physician must be taught to differentiate between different types of frequent movements that he may intelligently treat them, or refer the patient to the proper specialist according to their cause; for instance, pyorrhea cases to the dentist; ear, nose and throat infections to the laryngologist; psychic and neurogenic disturbances to the neurologist; ptomain poisoning, gastrogenic or enterogenic dyspepsias to the gastro-enterologist; functional and organic disease to the practitioner or internist, and inflammatory, ulcerative or obstructive lesions of the small intestine, colon or rectum to the coloproctologist.

INFLAMMATORY AND ULCERATIVE ENTEROCOLITIS (DIARRHEA)

Usually diseases causing diarrhea are characterized by inflammatory or obstructive intestinal lesions, formerly discussed under the captions of intestinal catarrh, tuberculosis, syphilis and dysentery; but increased knowledge concerning the etiology of diarrhea makes this classification untenable.

The term "dysentery" is often applied to intestinal ailments characterized by the syndrome of abdominal pain, rectal tenesmus and fluid evacuations containing blood and mucus; but the appellation is confusing, since it has no etiologic significance, and dysenteroid manifestations complicate all ulcerative intestinal affections.

Generally chronic diarrhea is incited by colitis. Would it not be wise to forget so-called "dysenteries" and to classify inflammatory and ulcerative intestinal lesions etiologically, an arrangement that would permit their discussion under the headings of catarrhal, tuberculous, syphilitic, gonorrheal, endamebic, bacillary, balantidic, flagellate, coccidic and helminthic colitis and enterocolitis?

Catarrhal Enterocolitis.—This affection is quite common, and may be associated with constipation or diarrhea, when the mucosa is inflamed, excoriated or ulcerated. Catarrhal colitis can be relieved usually without surgery when the patient abstains from violent exercise or work, adheres to a suitable diet, and takes medicine to lessen fermentative and putrefactive changes, to destroy intestinal bacteria, to minimize toxins, to allay peristalsis and to heal the bowel. In neglected cases, when the small and the large intestines are involved by numerous ulcers, colonic medicated irrigations and high oil and bismuth injections sometimes effect a cure; but when they fail, the abdomen should be opened and a catheter inserted into the ileum, cecum or appendix, and the bowel flushed daily with physiologic sodium chlorid or medicated solution until the lesions are healed and the diarrhea subsides.

---

* Read before the Section on Gastro-Enterology and Proctology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Syphilitic Colitis.—Enteritis and colitis syphilitica are rare, but intestinal syphilis rapidly destroys the mucosa or induces stricture. The process makes the intestine brittle, and in two of my cases the bowel broke in two while being lifted into the wound. Good results are obtained by extirpation of the involved intestine; but when the patient declines radical operation, jejunosigmoidostomy or ileosigmoidostomy or rectostomy is indicated.

Urgent manifestations occasionally make ileostomy or colostomy imperative to prevent death from perforation or obstruction.

Two of my patients in whom an artificial anus was established for syphilitic diarrhea, one seventeen, and the other twenty-five years ago, are earning their living. Salvarsan or antisyphilitic drugs alone are valueless when the intestinal mucosa is extensively ulcerated or the bowel stenosed.

One hesitates about extirpating the rectum, when distorted by a syphilitic stricture and ulceration, since the operation is tedious and more hazardous than proctectomy for cancer, owing to adhesions and brittleness of the intestine.

Gonorrheal Enterocolitis.—I have never known gonococci to attack the small intestine, but I have treated many patients for gonorrheal colitis and proctitis. Usually I have been able to arrest the inflammatory process and control diarrhea, pain and rectal tenesmus by daily colonic irrigation, using a 4 per cent. solution of argyrol or a 2 per cent. solution of ichthyol.

Endamebic Enterocolitis.—Endamebiasis, common to tropical countries and temperate zones, has been encountered frequently in the United States, since we took possession of Porto Rico, and the Hawaiian and the Philippine Islands. The disease is caused by *Endameba histolytica*, an organism difficult to eliminate permanently because it embeds itself in the mucous membrane and submucosa and breaks out and reinfects the bowel following an apparent cure.

Endamebiasis is characterized by chronic diarrhea with mucus, pus and blood in the stools, and loose movements are caused by an inflammed or ulcerated mucosa, endamebic hepatic abscess or intestinal stricture.

The manifestations and degree of diarrhea induced by endamebiasis depend on the segments of bowel involved and the degree of ulceration, for in the beginning, denuded areas are few, small and superficial, but when there is mixed infection, the mucosa of the colon and the rectum is distorted by superficial or undermining ulcers having intercommunicating fistulas.

Abdominal pain, diarrhea, hemorrhage and tenesmus are mitigated by rest, dietary, oil enemas, colonic irrigation and antidiarrheal drugs, but aggravated endamebiasis is rarely cured without surgery, though temporary improvement has followed the administration of from 20 to 30 grains of ipecacuanha or 1/4 grain of emetin administered as required.

The lesions may be confined to the colon and rectum, but in several of my cases the lower ileum was infected and patients complained of terrific colic, abdominal distention, explosive fluid and acrid, foul-smelling stools.

Drainage through the appendix or cecum is not effective when the ileum is involved, and my enterocecostomy, which provides a means of separately or simultaneously irrigating the large and small intestine, meets indications in these cases.

Appendicostomy and cecostomy are a godsend to patients afflicted with endamebic or other types of ulcerative colitis, because they are easy to perform, are not dangerous, and provide a vent for through and through medicated irrigation, which frees the intestine of pathogenic organisms, acrid discharge, toxins and irritating débris, relieves autointoxication, heals ulcers and arrests diarrhea.

Ichthyol, 2 per cent. and hydrogen peroxid, 5 per cent., the irrigants of choice, are superior to quinin.

When the patient is exhausted from starvation, diarrhea and hemorrhage, the colon is irrigated twice, but in less urgent cases daily flushing is sufficient. Recovery is prompt following direct bowel treatments, and usually the patient gains rapidly in weight.

Hepatic abscesses complicating endamebiasis are opened and drained.

Bacillary Enterocolitis.—This affection is common in China, Japan and the tropics, and is more virulent when caused by Shiga's than by Flexner-Harris', Hiss', Park's, Duval's or other dysenteric bacilli.

Bacillary colitis is encountered in France, Germany, Russia, the United States and other cold climates, but usually in epidemic form and most often in unhygienic penitentaries, insane asylums and barracks.

The infection rapidly destroys the mucous membrane by ulceration or diphtheric sloughs unless arrested by the serum treatment.

Abdominal pain, frequent bloody evacuations and rectal tenesmus disappear in from three to four days in mild, and in from four to six days in aggravated cases following the injection of serum, except when it is not powerful or the patient has an idiosyncrasy against it. Sometimes several weekly injections are required to cure diarrhea.

Since serums are useless in endamebic colitis, this form must be differentiated from the bacillary type.

Serums are not effective in the presence of mixed infection, or when the intestine is distorted with ulcers, fistula or stricture.

I have cured many patients with appendicostomy, cecostomy or my enterocecostomy and frequent colonic flushing, using antiseptic, astringent or healing solutions. In extreme cases characterized by colonic distortion, excision, short-circuiting or establishment of an artificial anus served their purpose.

Since the surgical treatment of balantidic, flagellate and coccidic colitis is similar to that outlined for endamebic chronic diarrhea, they will not receive further consideration.

Helminthic Enterocolitis.—This affection is rare, but frequent evacuations may be caused by irritation from tape worms, strongyloid or lumbricoid worms, flukes, whipworms, threadworms and hookworms, or obstruction may be induced by a collection of parasites. Usually helminthic colitis is relieved or cured by purgation, vermifuges and high chemical injections, but enterotomy and colotomy have been employed when evacuating worms, and twice I succeeded in eliminating the parasites with their ova by appendicostomy and cecostomy followed by bowel flushing.

Tuberculous Enterocolitis.—The intestinal segments (duodenum, jejunum and upper ileum) coming first in contact with the organisms are seldom involved, while the ileocolic angle is attacked in 85 per cent. of cases.

Tuberculous foci may originate in the mucosa and extend to deeper tunics or begin in the serosa.

There are several varieties, namely, *superficial-ulcerative*, *deep-ulcerative*, *neoplastic*, *fibroplastic*, glandular and peritoneal, the first three being the most common.

Surgical intervention is indicated in bowel tuberculosis when other measures fail, infection is virulent, hemorrhages frequent, diarrhea is exhausting, the patient's strength is being rapidly depleted, and when there is complicating perforation, peritonitis, stricture, abscess or fistula.

Operative interference is contraindicated when the sufferer is dying from phthisis or tuberculous lesions elsewhere.

When through and through irrigation by way of the appendix or cecum fails to cure ulcerative colitis, it is because irrigations are not copious, not properly medicated or they are always carried out with the patient in the same posture, which prevents the fluid from coming in contact with all sides of the diseased intestine.

Local gas or gas-oxygen is preferred to ether anesthesia, because the latter aggravates pulmonary foci.

Successful operations accomplish removal of the disease, diversion of the fecal current, or provide for through and through colonic irrigation.

Depending on their location, tuberculous foci are extirpated by enterectomy, cecectomy, sigmoidectomy or proctectomy. Short-circuiting is accomplished by entero-anastomosis or unilateral or bilateral exclusion; and through and through bowel flushing is achieved by ileostomy, appendicostomy, cecostomy or my enterocecostomy.

Resection is the procedure of choice, and tuberculous subjects stand the operation well, except when adhesions are extensive or the bowel is severely traumatized, and the removal of a few inches more of the intestine does not make the undertaking more hazardous.

Occasionally preliminary exclusion, appendicostomy or cecostomy are advisable to prepare the patient properly for radical operation.

I have short-circuited the small or large intestine ten times for tuberculosis, and putting the bowel at rest markedly benefited eight patients.

Usually I perform appendicostomy or cecostomy in connection with exclusion, in order that by through and through flushing I may prevent the backing up of feces and treat lesions directly.

Short-circuiting is not always satisfactory, because it is more often palliative than curative; convalescence is longer than following extirpation; bacilli-laden discharge continues to pass over healthy intestine; the disease sometimes attacks the anastomotic opening, necessitating a second operation, and no attempt is made to extirpate tuberculous glands.

Appendicostomy, cecostomy or Gant's enterocecostomy is indicated when the patient is being weakened by diarrhea, bacterial or chemical toxemia, hemorrhages, gas accumulation, colic, tenesmus or burning pains incident to acrid discharges, and when enteroclysis by way of the anus fails.

Through and through irrigation palliates or cures superficial and deep ulcerative types, but rarely benefits neoplastic, fibroplastic, glandular and peritoneal enterocolonic tuberculous foci which require extirpation.

OBSTRUCTIVE (MECHANICAL) ENTEROCOLONIC DIARRHEA

This represents a type of diarrhea in which evacuations are made frequent or liquid by lesions that block the bowel. Patients of this class complain of constipation, then obstipation, alternating with loose movements, and finally diarrhea when obstruction is marked.

Obstructive diarrhea is usually mistaken and treated for diarrhea caused by gastrogenic, enterogenic and neurogenic disturbances, because physicians fail to examine properly the abdomen, colon and rectum. It seldom originates in the small intestine, but lesions responsible for it are common to the colon, sigmoid flexure and rectum.

Diarrhea is attributable to valvelike fecal masses that irritate or obstruct the intestine, and to stercoral ulcers that augment peristalsis.

The following lesions may cause loose evacuations or alternating diarrhea and constipation: congenital deformities, extra-intestinal pressure, stricture, tumors, foreign bodies, intestinal calculi, fecal impaction, adhesions, angulation, diverticula, pericolic membrane, sacculations, diseased mesentery, volvulus, kinks, hernia, invagination, procidentia recti, enteroptosis, colonic dilatation, enterospasm, parasites, hypertrophy of O'Beirne's sphincter, the rectal valves, or levator ani and sphincter muscles, coccygeal deviation and anorectal affections.

Obstructive diarrhea has a complex etiology and different operations are required to relieve it, many of which are effective and bring good results.

Congenital anorectal deformities are common, but colonic malformations are rare. In partial congenital colonic obstruction, nonoperative measures work temporarily; but when it is complete or almost complete the deformity must be corrected or excised.

Anorectal occlusion caused by narrowing of the anal canal, a membranous partition or fibrous band, is corrected by a free incision and subsequent rectal divulsion.

When the anus is imperforate, the rectum is dissected free and sutured in the anal region, and complicating fistula is eliminated by closing the opening following repair of the rectum.

Extra-abdominal pressure causing diarrhea is removed by destroying adhesions, anchoring the uterus, excising the prostate or extirpating the tumor compressing the bowel.

Strictures involving the small intestine, colon or sigmoid flexure are excised unless inoperable, when obstruction is relieved by exclusion or colostomy. Rectal stenoses are difficult to remove, and, barring deplorable instances, obstruction is overcome by posterior proctotomy and dilatation, or colostomy and putting the bowel at rest.

Benign and malignant tumors cause persistent diarrhea, which continues until they are excised, short-circuited or an artificial anus is made. Colonic resection is indicated, since it effects a cure, and lateral anastomosis with a large opening is preferable to end to end anastomosis, which frequently leads to obstruction and recurrence of diarrhea.

Rectal cancers, according to their location, are extirpated by perineal, vaginal, sacral or abdominoperineal proctectomy, except when inoperable, and then colostomy is performed.

Polypi of the large intestine are treated like cancers, but rectal polyps are ligated and excised or removed by attaching my valve clamp to their pedicles.

Occasionally rectocolonic papillomas are cured by frequent colonic irrigation.

Foreign bodies inducing diarrhea are evacuated with high oil enemas, but when encysted or caught in a bowel kink, enterotomy or colotomy is required. Free bodies in the rectum are drawn through the proctoscope with forceps, but when imbedded, or if they have sharp angles, divulsion or division of the sphincter facilitates their extraction.

Colonic fecal impaction consequent on constipation, enterospasm or obstruction induces coprostatic diarrhea, until offending scybala are expelled by castor oil, massage and frequent high oil or hydrogen peroxid enemas, which disintegrate the masses so they can be washed out.

Fecal impactions in the sigmoid and rectum are broken up with a gouge through the proctoscope, or with the finger when low, after which they are evacuated by irrigation.

Adhesions causing obstructive diarrhea vary, and routine surgical procedures are impracticable. When threadlike or due to exudates, they are destroyed by massage, with the finger, or wiping glued intestinal loops apart; but organized fibrous bands and rigid sheathlike adhesions are exposed by celiotomy, and severed or dissected from the bowel. Their reformation is lessened by covering raw areas, floating the bowel in sterile oil or saline solution, encouraging postoperative peristalsis, and frequently changing the patient's posture.

Resection, exclusion or an artificial anus is indicated when the intestine is completely incapacitated by undestroyable adhesions.

Pericolic or Jackson's membranes compressing the bowel are eliminated by ligating and severing their attachments and peeling them from the cecum or colon; but, in deplorable instances, the involved intestine is excised or excluded, or a vent is made above the block.

Angulations and twists are treated as above if caused by adhesions, but when due to ptosis, the intestine is straightened, replaced and anchored to the anterior or posterior abdominal wall by colopexy, unless its functionating power is permanently destroyed, in which case extirpation, short-circuiting or an artificial anus is imperative.

Chronic invagination of the sigmoid flexure into the rectum complicated by coprostatic diarrhea is quickly and permanently relieved by sigmoidopexy alone, or in conjunction with colopexy.

Colonic dilatation is quickly corrected by coloplication reinforced by colopexy; but when caused by constricting adhesions they are eliminated, or obstruction is relieved, by colectomy, ileosigmoidostomy or a cecal anus.

Diverticula occasionally induce frequent evacuations containing foul-smelling pus. Small pouches are ligated and removed, buried by inversion and suture or extirpated by elliptical incisions and closure of the wound; but large and inflamed diverticula complicated by peridiverticulitis or abscess are excised. Short-circuiting and colostomy are contraindicated unless there is perforation, or an abscess or fistula.

Sometimes a cure is effected by dissecting out the fistulous sinus opening, cleansing and draining the diverticular cavity, reinforced by suturing the bowel opening.

Splanchnoptosis, enteroptosis and coloptosis often cause alternating diarrhea and constipation that continue until ptotic organs are reanchored by gastropexy, colopexy, sigmoidopexy and nephropexy alone or combined.

Enterospasm is controlled by hot water drinking, high warm enemas, hot abdominal fomentations, and belladonna continued until intestinal contractions, colic, constipation and diarrhea are relieved. Where enterospasm is prolonged and causes partial or complete obstruction, resection or an artificial anus is sometimes indicated.

Hypertrophy of O'Beirne's sphincter at the rectosigmoidal juncture is occasionally responsible for obstructive diarrhea, and when not relieved by hot fomentations and belladonna, topical application to ulcers or stretching the narrowed intestine with an inflatable rubber bag, extirpation or exclusion may be necessary.

Thickened rectal valves responsible for coprostatic diarrhea are eliminated by my valvotomy.

Sphincteric hypertrophy producing constipation and diarrhea, formerly treated by divulsion under ether, is immediately overcome by severing the muscle, following eucain infiltration.

Fissure-in-ano inducing sphincteralgia and fragmentary evacuations is quickly cured by splitting the anal canal under eucain anesthesia.

Hemorrhoids responsible for diarrhea are infiltrated, ligated and excised.

Procidentia recti is corrected by linear cauterization, removal of rectal flaps, or, in aggravated cases, by reinforcing these procedures by sigmoidopexy.

Coccygeal Abnormalities.—When the bone obstructs or perforates the rectum, coprostatic or irritating diarrhea ensues and continues until the coccygeal tip is excised.

In cases of mechanical diarrhea, however, produced when the bowel is atonic, dilated or partially paralyzed, or the patient suffers from autointoxication, removal of the obstruction does not cure unless reinforced by tonics, stimulation of the emunctories and colonoclysis to eliminate the toxins.

Finally, in deplorable cases of obstructive diarrhea with toxemia, I perform appendicostomy or cecostomy, when getting rid of the block, that the bowel may be cleansed of toxins and débris by through and through irrigations.

CONCLUSION

I would emphasize the frequency with which surgery is indicated in treating chronic enterocolonic diarrhea, and the rapid curability of the condition by operation reinforced by the therapeutic measures outlined.

Military Medicine and Surgery

THE EAR AND AVIATION

ISAAC H. JONES, A.M., M.D.
Major, M. R. C., U. S. Army
PHILADELPHIA

In aviation we have a practical example of the importance of the ear in maintaining equilibrium. It is now recognized that equilibrium is made possible by three senses—the balance-sence of the internal ear, sight, and a group of general impressions which for convenience is called the "muscle-sense." It is not necessary for an individual to have perfect internal ears, perfect sight and perfect muscle-sense in order to have good equilibrium. If the internal ears are impaired, the individual can maintain his equilibrium by means of sight and the muscle-sense; if his sight is impaired, the ear-sense and the muscle-sense enable him to maintain his balance; and if his muscle-sense is impaired, as in tabes, his ear-sense and sight are sufficient to enable him to stand and walk with confidence and accuracy. For this reason we must remember that, through various toxemias, such as mumps, syphilis and the infectious fevers, a person may have an impairment and even a complete destruction of his ear balance-sense and yet not be in any way conscious of this defect, simply because his sight and muscle-sense make it possible for him to maintain his equilibrium.

These facts, however, take for granted that the individual is on "terra firma." When the human being becomes a bird, as it were, he suddenly finds himself in an entirely new environment. Without functionating internal ears, it is impossible for a person to be a good bird-man. When flying through the air, on what does the aviator rely in order to maintain his equilibrium and that of the aeroplane? Can he rely on sight? Hardly; for when he is sailing through the clouds or darkness, his eyes cannot give him the slightest information about his position in space—not even whether he is right side up or upside down. As regards the muscle-sense, it is undoubtedly true that it plays a certain part; but when the aviator is seated on an unstable and rapidly moving machine, it is hardly conceivable that the weight of his body could determine and maintain his position in space merely by the sensing of gravity. In order, therefore, to preserve that wonderful accuracy necessary in controlling such a delicate mechanism as the flying machine, he relies preeminently on his *ear* balance-sense. It is easily conceivable that some of the unexplained accidents in aviating may be due to a concussion of the internal ear produced either by the deafening roar of the engine or by the decrease of the air-pressure when at great heights. Also in a rapid ascent from a denser to a rarer air there occurs an oxygen insufficiency which has a direct effect on the ear-mechanism through the blood stream. It is also highly probable that many an aviator has gone to his death because, all unknown to him, he did not possess a normal ear-mechanism; in the presence of a combination of difficulties in which all normal faculties would be requisite, because of an imperfect ear-mechanism he was unable to maintain his balance.

To realize the importance of the ear in the matter of flying, it is only necessary to consider a bird flying in a cloud. His muscle-sense naturally means practically nothing to him; his sight is of no help. He relies almost exclusively, therefore, on normally functionating semicircular canals, which, as we know, are wonderfully developed in the bird.

Summarizing, therefore, even when an individual is standing or walking on the earth, his ears constitute his sense-organs of balance; as long as he remains on the earth he has in addition the contributory help of information received from his muscle-sense and his sight. When he rises above the earth and flies in the dark it is obvious that these contributory factors are practically eliminated and that he must rely almost exclusively on the ear balance-sense.

Since normal internal ears are such an asset—in fact a prime requisite—for the aviator, common prudence would suggest a most careful examination of the degree of function of one's internal ears before taking up flying as an occupation. The ear-tests furnish exact and mathematical data concerning the function not only of the internal ear, but also of the entire vestibular apparatus; this includes the ears themselves, the eighth nerve, the brain-stem, the cerebellum and the entire balance-mechanism.

When it was announced that a state of war existed between the United States and Germany, it at once became apparent that a tremendous number of aviators must be secured for the military service within the shortest possible time. The medical problem consisted of selecting thousands of physically equipped candidates for aviation and placing them in training for war service immediately. The Medical Department found it necessary to decide on new methods of physical examination and to adopt new standards of physical qualifications for this branch of the service. This had to be done not merely for one place or for one examining group; it was necessary to make the tests practicable for cities in all parts of the United States, without, at the same time, in any way lowering the requisite rigid standards or lessening the completeness of the examination. How could this be done? In a word, such an ideal could be attained only by: (1) the standardization of the tests, and (2) the standardization of the *examiners*.

STANDARDIZATION OF TESTS

The methods presented in this paper were adopted in May, 1917, as the standard for the United States Army. The following briefly summarizes the fundamental principles underlying the examination for aviators. The aviator must be in a sense the "superman." He must have $^{20}/_{20}$ vision without glasses. He must have $^{40}/_{40}$ hearing. Such requirements are higher than for most branches of military service. A candidate for every branch of service must conform to a certain physical standard; he must be a normal man, such as would satisfy the average life insurance company, with the additional requirements of a certain relative height, weight and chest measurement, and a definite visual and auditory acuity. Like any other candidate for service, the aviator must conform to all these requirements and in addition must possess visual and auditory acuity to a high degree. There is, however, an attribute not required by any other branch of the military service that is indispensable to the perfect aviator—a good *balance-mechanism*. Therefore the peculiar test, applied to the aviator alone, is the special examination of the equilibratory portion of the internal ear.

So presented in the official blank, the equilibrium and the vestibular tests are made thus:

The nystagmus, past-pointing and falling after turning are tested. The turning-chair must have a head-rest which will hold the head 30 degrees forward, a foot-rest and a stop-pedal. (The American Modification of the Bárány chair is officially required. This made possible the establishment of an absolute standard. While the tests could be made by using other types of turning-chairs, an exact quantitative estimation of the responses can be definitely established only by the use of a standardized chair.)

(*a*) *Nystagmus.*—First of all, a spontaneous nystagmus must be looked for. It is noted whether there is any twitching of the eyes when gazing straight ahead, or looking either to the extreme right, the extreme left, up or down. With the head forward 30 degrees, the candidate is turned to the right, eyes closed, ten turns in twenty seconds. The instant the chair is stopped, the stop-watch is clicked; the candidate opens his eyes and looks straight ahead at some distant point. There should occur a horizontal nystagmus to the left of twenty-six seconds' duration. The candidate then closes his eyes and is turned to the left; there should occur a horizontal nystagmus to the right, of twenty-six seconds' duration. A variation of ten seconds is allowable (either as low as sixteen seconds or as high as thirty-six seconds).

(*b*) *Pointing.*—1. The candidate closes his eyes, sitting in a chair facing the examiner, touches the examiner's finger held in front of him, raises his arm to the perpendicular position, lowers the arm, and attempts to find the examiner's finger. This is done first with the right and then with the left arm. The normal person is always able to find the finger.

2. The pointing test is repeated after turning to the right, ten turns in ten seconds. During the last turn, the stop-pedal is released, and as the chair comes into position, it becomes locked. The right arm is tested, then the left, then the right, then the left, until candidate ceases to past-point. The absolutely normal will past-point to the right three times with each arm, if needless delay is avoided. (However, one past-pointing to the right of each arm qualifies, if the nystagmus and falling are normal.)

3. The past-pointing is repeated after turning to the left. (Similarly one past-pointing of each arm to the left qualifies, if the nystagmus and falling are normal.)

(*c*) *Falling.*—The candidate's head is inclined 90 degrees forward. He is turned to the right, five turns in ten seconds. On stopping, the candidate quietly sits up, eyes closed, and should fall to the right. This tests the vertical semicircular canals. He is turned to the left, the head forward 90 degrees; on stopping, he again sits up, and should fall to the left.

Obviously these tests as presented in this blank are not intended to make a diagnosis of a pathologic lesion. The object is merely to determine *whether or not the ear-mechanism is normal.* If, in these tests, the candidate shows normal responses in nystagmus, past-pointing and falling, he is fit for the Aviation Service; if he does not, he is unfit for that service. These simple turning-tests eliminate all unnecessary time-consuming diagnostic procedures. The entire series of tests as outlined in the blank requires only three and three-fourths minutes, and yet in this short time we are able to determine the integrity of the internal ears, the eighth nerves, and the pathways through the medulla oblongata, the pons, the six cerebellar peduncles, the cerebellum itself and the cerebral crura to the cerebral cortex.

Incidentally, these tests are in no sense severe, and are in fact seldom regarded even as unpleasant. Occasionally nausea occurs after a few turnings; it is then merely necessary to stop the examination for the time being and to complete the remainder of the tests after an interval of a half hour. There is no need whatever to make these tests in any way distressing to the candidate.

These turning-tests quickly separate the obviously fit from the unfit. The majority of the candidates show normal responses; no further testing is required, and they therefore qualify and are accepted. Some candidates show such markedly subnormal responses that they are immediately disqualified and rejected. A limited number give what might be termed "border-line" responses; the question then arises, Has this particular applicant *sufficient* balance-sense to become an aviator? It is here that the caloric test is useful. The turning has tested both the right and the left ears simultaneously. The caloric method enables us to test each ear separately. Water at 68 F. is allowed to run into the external auditory canal from a height of about 3 feet through a stop-nozzle, with the head tilted 30 degrees forward, until the eyes are seen to jerk or the individual becomes dizzy. The length of time from the beginning of the douching until the jerking of the eyes becomes apparent, or until the applicant says he is dizzy, is accurately measured by a stop-watch. The type of nystagmus is then noted. It should be rotary, and the direction of the jerk should be to the side opposite to the ear douched. The length of time shown by the stop-watch in the normal is forty seconds. The eyes are then closed and the past-pointing is taken. The head is then immediately inclined backward 60 degrees from the perpendicular (or 90 degrees from the original position). There should then appear a *horizontal* nystagmus to the side opposite to the ear douched. The eyes are then closed, and the past-pointing is taken with the head in this position. The left ear is then douched, and the same procedure carried out. If the caloric test applied in one of these "border-line" cases shows only a slight impairment of the responses from each ear, the candidate is qualified. A slight impairment would be indicated if, instead of the normal forty seconds of douching, there was required not more than ninety seconds of douching. If one ear shows normal responses, whereas the other ear shows responses only after *more* than ninety seconds of douching, the candidate is disqualified. Care should be taken to be certain that the cold water is reaching the drum-head during the caloric test, as wax or other obstruction in the external canal would interfere with the responses in a perfectly normal individual.

The examination of a candidate for the aviation service is a different matter from the examination of a patient. We are dealing with an alert mind, anxious to make the best showing possible. Many candidates feel that "jumping eyes" and evidences of vertigo are signs of weakness and would be counted against them. Because of this anxiety, many candidates attempt to shorten the duration of the nystagmus by fixing the eyes on some near object. It is perfectly possible by the fixing of the eyes to shorten the duration of the nystagmus. It is a common experience in this work to note that when many observers are standing about the candidate and in his line of vision, the nystagmus is usually of short duration. If these observers are asked to stand back out of the line of vision, the same candidate almost invariably shows a longer duration of nystagmus. Further to obviate fixation of the eyes, it is always necessary to place the chair near a large window so that the candidate has an unobstructed view of an object placed at "infinity"—over 100 feet. Furthermore, instead of obeying the natural impulse to past-point, candidates frequently make a mental calculation as to the vertigo induced, and voluntarily attempt *not* to past-point. This is also true of falling. In such instances, the examiner, bearing in mind the type of individual with whom he is dealing, urges the applicant to "act perfectly naturally," and is then usually able to elicit a true response to the test. Supposing, however, that the candidate still fails to past-point, although he has shown a normal nystagmus and falling, we are able to decide the matter finally in the following way: First the quantitative estimation of vertigo is taken. The after-turning vertigo is measured as follows. The candidate is turned to the right, ten turns in ten seconds with the eyes closed. As he is being turned, he is asked to describe his sensations and to keep on telling in which direction he feels he is being turned; thus he will say, "To the right, to the right, to the right," etc., until the chair is stopped; then he will feel himself turning in the opposite direction and will say, "Now I am going to the left, to the left, to the left," etc., when as a matter of fact he is sitting perfectly still in the chair. The duration of this sensation of vertigo from the time that the chair is stopped until he ceases to feel that he is going to the left is taken in seconds with the stop-watch. The normal should show an after-turning vertigo of twenty-six seconds. The test is then repeated by turning to the left, and the candidate should exhibit a vertigo in the opposite direction of twenty-six seconds. Should the candidate show over sixteen seconds of vertigo in both directions, having previously shown a normal nystagmus and falling, the examiner then realizes that the absence of past-pointing was probably due to a calculated correction rather than to any pathologic condition. The question is definitely determined by douching the ears. Although a candidate can estimate the significance of the sensation of vertigo after turning, he has no control over this sensation after douching; he is unable to calculate the meaning of the vertigo produced by the caloric test. Therefore, if he fails to past-point after the douching-tests, he is definitely disqualified.

STANDARDIZATION OF EXAMINERS

So much for the standardization of the tests themselves. Equally important was the problem of the standardization of the examiners. For this purpose a medical officer was sent under special orders to each of thirty cities throughout the United States, and in each one of these cities there was established a medical unit for the examination of candidates for the Aviation Service. The requirements of the tests were fully explained to each medical unit, so that not only the same equipment is used, but also exactly the same technic. This rendered it impossible for any candidate to say, "I wish I had been examined in a certain city where the tests are easy, rather than in a certain other city where the tests are exacting." Those otologists were selected who were most expert in the Bárány-tests, and given intensive training by the medical officer sent for the purpose of establishing a uniform technic. Thus, in a few months the testing was put on an absolutely uniform basis in all examining centers.

In order to save time, already existing institutions, such as large hospitals or state universities with their equipments, were utilized as these examining centers. Volunteer staffs of civilian consultants were locally organized, and the work of the examining centers systematized to a point of highest efficiency, with the result that within a few days of the arrival of the medical officer at the examining center the work was in full swing. By this method of *decentralization*, the examination of thousands of applicants in a minimum space of time was made possible. First of all it was necessary to make sure that those in charge of each examining center were fully equipped and capable to make these tests; this once assured, full authority and responsibility were vested in the medical officer in charge of each center. Thirty medical aviation centers, each examining from ten to forty candidates a day, provided immediately the thousands of men required.

It is obvious to the candidate himself, that if he is deficient in his ear balance-sense he is not only a danger to the service, but he is also unnecessarily imperiling his own life when he attempts to fly. Certain members of the medical profession and certain veteran fliers, because of the newness of these methods, expressed skepticism in regard to their value. One physician, a member of an examining unit, was surprised to find that when he himself was examined, he showed an almost complete lack of ear balance-sense. The turning and caloric tests failed to produce nystagmus, vertigo, past-pointing and falling. This impairment of the ear-mechanism was directly traceable to a severe attack of mumps in childhood, during which he had suffered from both of the usual complications of mumps—an orchitis and an involvement of the internal ears. His skepticism was changed to enthusiastic conviction when he thus was made to realize that without the Bárány tests he would have had no conception of this physical disability, the only suggestion of which, up to that time, had been his knowledge that he did not become seasick.

All experienced aviators that have been examined have, without exception, shown normal responses in the turning-chair. Those veteran aviators whose attention has been called to these methods of testing have expressed their conviction of the practicability of the safeguards provided by these tests in determining whether or not a man has what they speak of as "air-sense.' One seasoned American flier of fifteen years' experience stated that his doubt changed to conviction after he was examined in the turning-chair; he volunteered a statement that from his intimate knowledge of the circumstances attending the death of at least three aviators, who were killed while flying, their failure to negotiate difficulties of no unusual degree which resulted in their death might now be understood as an expression of their lack of this sense. He further added that in his judgment, if these tests had been available in the early days of flying, many a life might have been spared.

The value of the past-pointing test is well illustrated by one candidate who proved to have a post-traumatic cerebellar lesion, which was first detected by the isolated absence of past-pointing of the left arm to the right. Neurologic examination then demonstrated classical signs of lesion of the left cerebellar hemisphere. Here was a man with distinctly impaired cerebellar function attempting to enter a service in which the utmost demands are made on the cerebellum.

One ardent applicant was disqualified because of a markedly impaired internal ear, in both the cochlear and vestibular portions. It has since been learned that he went to another country, where he was accepted in the aviation service as a flier. Obviously the requirement in that country is not so high as in the United States. At the present time in the United States a high standard is required because this country is in a position to pick and choose. The vast numbers of splendid applicants makes this possible. For this reason these hand-picked men will constitute not only the largest but also the most capable and finest aviation service in the world.

THE METHOD OF EXPERIMENT IN MEDICINE

"In a country rich in gold, observant wayfarers may find nuggets on their path; but only systematic mining can provide the currency of nations. In the search for natural knowledge, the experimentalists are the miners." There is a peculiar appropriateness in these words of Gowland Hopkins of Cambridge University at a time when men's minds are diverted by the great emergencies of war and are upset by the distorted values of every-day life. Nowadays it would require a foolhardy person to maintain that "there is nothing new under the sun," or to prophesy what cannot be done. The progressive evolution of science is expressed in the arts exemplified daily before us. We marvel at the newest phase of the conquest of the upper air or the ocean depths, at the irresistible force of the newest explosive or the perfection of the latest motor, all too often oblivious of the great strides that experimentation in medicine has brought about.

It is always refreshing and not infrequently stimulating to indulge in retrospect. What currency have the experimentalists in medicine provided in the passing years? The history of bacteriology and the entire structure of the modern conception of infectious diseases is a triumph of the experimental method. The real causes of diseases known from earliest history have been elucidated so that the modern therapeutist can build on the basis of this newer knowledge, and the sanitarian can prepare himself effectively for the struggle against invasion by micro-organisms. More recently even the diseases caused by pathogenic protozoa have yielded their story to the experimentalist.

Less startling, perhaps, but equally unique in its disclosures has been the discovery of the functions of internal secretion. The story of the pancreas, the thyroid structures, the suprarenals, the pituitary, the corpus luteum and the sex glands, each in turn presents a new point of view of regulation that takes us out of the domain of pure speculation into the field of biochemistry. It is only a few years at most since we were totally ignorant of these things. How imperfect and hampered medical thought would appear today without them! Added to this is the inroad already made in the experimental study of natural immunity to which clinical medicine already owes a great debt.

It is well for those strenuously engaged in the daily routine of the physician's life to recall some of these illustrations. The art of the physician, says Hopkins,[1] remains as before, a noble and difficult one, which must always call for special personal endowments; but experiment has widened the knowledge on which it is based, and experiment alone could have secured the progress which the last half century has witnessed.

We cannot expect the public to wax enthusiastic over something that those most concerned fail to appreciate; nor can we hope for their much needed support in any feature of medical progress that the physician himself does not heartily endorse. Experimentation in medicine belongs to a profession rather than to a trade, and therefore is not purely self-supporting or conducted solely for gain. But, as Hopkins has formulated the matter, it is not financial assistance alone that the nation should provide for the investigator. This is not even the most important stimulus that the nation can provide for him. Recognition and proper standing in the body politic are the investigator's due, and these, at least, should be forthcoming.

DANGERS IN THE MANUFACTURE OF ARSENICAL INSECTICIDES

Any one who makes even a casual inspection of a considerable variety of industries in this country must become convinced that despite the growing attention paid to the dangers of occupational conditions, there is still enormous room for improvement and reform. Too few of the industries in which workmen are menaced by harmful dusts, fumes or gases take cognizance of the menace to the extent of providing adequate safeguards, especially if they are not enforced by direct provision of the law. Industrial hygiene is still scarcely beyond its beginnings in many factories of this country.

An illustration of an industry that might have been expected to make better provision against dangers that must long have appeared obvious to even the uninitiated is furnished by recent investigations under the direction of the New York State Department of Labor[2] regarding dangers in the manufacture of Paris green and Scheele's green. These arsenical compounds, the poisonous qualities of which have been known many years, are at present manufactured by ten firms in the United States, of which firms seven are located in the state of New York. Fully 1,000 tons are produced annually, the material now being used chiefly as an insecticide. It appears that considerable illness exists among many of the workers engaged in the production of Paris green, an outcome due in a measure to a lack of knowledge among those engaged in its preparation, and a disregard of the extremely poisonous qualities that this salt possesses. The inspectors of the New York Industrial Commission's Division of Industrial Hygiene report that, as the workers are unacquainted with the dangerous and poisonous properties of the arsenical insecticides, many cases of arsenical poisoning are not discovered, because as soon as a slight irritation of the skin develops or nausea occurs, the men leave the industry, and the labor engaged therein is constantly shifting.

[2] Dangers in Manufacture of Paris Green and Scheele's Green, Special Bull. 83, State of New York Department of Labor, July, 1917.

The chief source of danger lies in the poisonous dust produced—not the irritating dust of some industrial operations, which has only a mechanical action and acts directly on the parts most exposed, nor infected dust, which carries pathogenic germs; but poisonous dusts, which are gradually absorbed and produce an actual intoxication. The New York investigators report, for example, the chemical analysis made on the air in one of the packing rooms in which the filling of boxes from barrels was performed. Three hundred and five mg. of Paris green were found per cubic meter of air at 60 F. This material occurring in the air was generated in the process of hand filling, blown off the walls and ceiling, and stirred up from the floor in the act of walking. A proper method of weighing and filling under enclosed hoods, clean walls and floors would have eliminated this large amount of dust. Samples of underclothing were analyzed and found to contain 1.1 mg. of Paris green in a piece measuring 6 square inches.

As the result of findings such as these, orders have been issued in plants wherever the labor laws are applicable against all conditions found to be detrimental to health. These orders relate to the prohibition of eating within the factory; the cleaning of floors, walls and ceilings; the provision of running hot water, soap and individual towels; the installation of exhaust systems to dispose of the dust created in the process of manufacture; the furnishing of a suitable place in which to eat meals, and the adoption of suitable means to remove dust from the floors. The inspection of the workers in the New York State factories shows the importance of periodic medical examinations for men engaged in the production of poisonous products. It is evidently useless, however, to provide up-to-date facilities for the comfort of workmen at mealtime if cleanliness throughout the plants is so neglected that the accumulated toxic materials are tracked into the room on the shoes of workmen. What is needed is better education of the workers respecting the poisonous properties of the materials with which they are concerned, and a greater sense of responsibility on the part of the manufacturers and employers for the health of their employees.

PROBLEMS IN THE CAMPAIGN AGAINST THE HOOKWORM

The important investigations on the incidence and control of hookworm disease that are being made in many parts of the world by the International Health Board of the Rockefeller Foundation have brought to light many striking facts. To the casual student of the subject, it might appear that the sole essentials in the management of a malady having a definitely ascertained etiology would be to eradicate the causative organism or eliminate the channels of infection, and to administer suitable curative agents to those already afflicted. The importance of soil pollution in the spread of hookworm disease is now clearly recognized in the campaigns being conducted against it; but in the tropical and subtropical belt, which is the native habitat of the hookworm in different parts of the world, unanticipated local and geographic conditions have placed some surprising obstacles in the path of progress in certain regions.

The hookworm surveys made in 1916 in Barbados and in British Honduras brought to light many striking facts, recorded in the latest report of the International Health Board. Thus they showed the important relation between geological structure and hookworm infection. The greater part of the island of Barbados is composed of porous coral limestone, which allows rapid seepage and percolation. The ground dries quickly, a condition unfavorable to the growth of young hookworms; and even though the thin superlying stratum of soil is polluted by fecal matter, this may easily seep away during rain. The smaller portion of Barbados, known as the "Scotland district," has an underlying structure of impervious sandstone and clay. This picturesque highland district shows heavy infection; it is estimated that in it 25,000 persons suffer from hookworm disease within an area of less than 25 square miles. In British Honduras, when other contributing factors have been eliminated, the rate of infection is seen steadily to increase as one travels south, following a change in geological formation from porous limestone to impervious clay.

In the East there has arisen a difficulty in relation to soil pollution that is of greater importance than the spread of hookworm disease. In western countries the problem of human sewage is primarily one of hygiene. In the East, as Heiser has pointed out, it is also a question of direct economic importance, owing to the use of excrement as fertilizer. In China, human excrement is a source of revenue to the state. The director-general of the International Health Board has thus presented the situation: Human excrement is the only fertilizer available in sufficient quantities to supply agricultural needs. China has no sewerage system. Each night in urban centers the excrement is collected by coolies, who carry it in wooden buckets to temporary storage depots outside the city walls. To these depots, farmers and gardeners go in tank boats to purchase supplies, which they convey up the rivers to their plantations of rice and mulberry. There they dig the excrement into the fields, or moisten it with water and sprinkle it over growing vegetation. A relatively light infection in Chinese cities may thus become a serious factor in spreading the disease to agricultural districts.

Here, then, agriculture and hygiene seem to clash. Secretary Greene of the Rockefeller Foundation states that the sudden stopping of soil pollution in China would mean the impoverishment of the soil unless some substitute were placed within the reach of the people. No such substitute is now available. If the problem could be economically solved in such a way as to utilize excrement without danger to the health of the people, the result would not only be of vast economic significance to the East, but might also prove of equal significance to countries in which the same material is entirely wasted. The time may come when, even in this enlightened country, the nitrogenous wastes of millions of persons will find some better utilization than the crude methods of sewage disposal now afford.

INCREASED RANK AND MORE AUTHORITY FOR MEDICAL OFFICERS

As most of our readers are aware, an amendment was introduced into Congress at the recent session which, if it had been adopted, would have given the medical officers in the Army the same rank that prevails in the Medical Corps of the Navy. Specifically the amendment provided that there should be twenty-five one-hundredths of 1 per cent. of major-generals, the same proportion of brigadier-generals, 4 per cent. of colonels, 8 per cent. of lieutenant-colonels, 23.5 per cent. of majors, 32 per cent. of captains, and 32 per cent. of lieutenants, *this to apply to both the regular and the reserve corps men.* Thus, if there are 10,000 medical officers in active service, there might be 25 major-generals, 25 brigadier-generals, 400 colonels, 800 lieutenant-colonels, 2,350 majors, 3,200 captains and 3,200 first lieutenants. This amendment lapsed without action by the ending of the session. The substance of the amendment, however, will be incorporated in a bill which will be introduced in both the Senate and the House at the coming session of Congress.

Medical officers must be equal in rank and authority with line officers if they are adequately to carry out the duties for which they will be held responsible. This fact has been emphasized by the experience of our allies in the present war, as well as by our own experience in the past. Our allies admit that in the beginning the medical officer did not have the rank, and consequently the authority, he should have had and that, for this reason, there have been grievous consequences. Among these was the disastrous experience of the British Army in the Mesopotamian campaign as a result of the failure of the medical service. The report of this tragedy, made by a board of nonmedical men, showed that lack of authority of the medical officers was an important factor. The medical officers were practically ignored. They were not advised as to the character of the expedition that was being undertaken, and as a consequence, they were unprepared for what happened. When later a medical officer made urgent representations in regard to the actual conditions obtaining, which in his opinion needed prompt action, he was threatened with arrest and removal from his post. When the actual results came the blame was thrown on the medical department, of which this medical officer was a member. The medical officers were censured because they had not protested more vigorously. We had a similar experience in 1898 when our medical officers were criticized for insanitary conditions at Chickamauga and elsewhere, although there was plenty of evidence to show that they had protested against these conditions to line officers. The whole sad story is told in detail in the Dodge report. There, also, will be found testimony that line officers treated with contempt the recommendations and protests made by medical officers. The medical officer is without influence simply because his shoulder straps indicate lower rank than that of the line officer with whom he is associated. Some may sneer, but the fact remains that it is rank that counts in both the Army and the Navy.

Of course rank brings with it increased pay. This, however, is immaterial. At the same time, it should not be forgotten that most of the physicians now in the Medical Reserve Corps have not only left the comforts of their homes, but also have given up practices which in the majority of instances yielded far more income than the pay they would receive as medical officers of the Army even if they had conferred on them the highest rank that the proposed law would provide. Among these medical reserve officers are many of the most prominent men in our profession, including the leading men in the specialties, as well as our best surgeons and internists.

When the war broke out there were less than 450 medical officers in the regular Army Medical Corps. Today there are commissioned, including officers of the regular Army, the National Guard and the Medical Reserve Corps, at least 17,000 physicians. Less than 1,000 are in the regular Army Medical Corps. Under the present law these regular Medical Corps officers are entitled to the grades of lieutenant-colonel and colonel; and in the case of the surgeon-general, to that of brigadier-general[1]; the highest rank that can be conferred on any one of the other 16,000—that is, on any reserve medical officer—is that of major.

---

[1] Surgeon-General Gorgas has the rank of Major-General by special act of Congress.

May we remind our readers that the men in active service will be prevented by the regulations from using their influence in this matter, and that the duty of pushing this measure rests on those who stay at home? Every physician has representing him in Congress one man in the House of Representatives and another in the Senate. If every physician will let his representatives know that this proposed measure should become a law, and if in addition he will enlighten his neighbors in regard to the matter, an effective public opinion will be created. The time is opportune; congressmen are at their homes. Write or speak to your representatives now; get your neighbors to do likewise—not for the good of the medical profession, but for the good of the service.

Current Comment

SOME CRITERIA OF ABNORMALITIES IN MILK DUE TO THE STAGE OF LACTATION

According to the standard adopted for certified milk by the American Association of Medical Milk Commissions, cow's milk obtained within a period of forty-five days before parturition is excluded from use as a human food. This regulation is based on the widely accepted assumption that pregnancy influences the normal composition of milk. To test the supposition, Palmer and Eckles[1] have conducted an analytic investigation of a number of cows of various breeds in the herd of the department of dairy husbandry at the University of Missouri. Selecting as standards for the limits of normal composition the figures 4.5 per cent. for fats and 4 per cent. for proteins, they ascertained very conclusively that the stage of gestation bore no evident relation to the time when the milk and milk fat passed the limits of normality chosen for comparison. The changes in the composition may, indeed, become very marked at various periods in the milking cycle, exhibiting a high protein and fat content and an abnormal composition of the milk fat. The new comparative analyses indicate that the abnormalities, in the sense of extremes of composition, to which cow's milk is subject when parturition is approaching, are in reality due largely, if not entirely, to the stage of the lactation period. The duration of this varies considerably for different individuals. Palmer and Eckles state that cow's milk shows anomalies as soon as the lactation stimulus becomes an artificial one on the part of the dairyman. Many cows show the abnormalities several months before the next parturition; while cows that are very heavy producers with periods of parturition the usual interval of twelve to thirteen months apart may continue to produce perfectly normal milk up to the very hour of the next parturition. If the stage of lactation is the crucial factor in determining aberrations in the composition of the milk, how is the end of the period to be recognized? This question is not easily answered, except on the basis of chemical analysis. The Missouri experts suggest that the percentage decrease in the milk flow from that when the cow was fresh affords some indication. They offer this practical advice: The milk from cows giving as low as a half-gallon a day should certainly be regarded with suspicion, and should be subjected to critical analysis, especially when the feeding of infants and children is concerned.

THE FEEDING OF WAR PRISONERS IN GERMANY

Among the duties that attach to the Medical Department of the Army in war is the inspection and supervision of the mess management, including not only the quality and quantity of the food, but also the hygiene of its preparation and distribution. This applies equally well to the prison camps, in which immense numbers of men are housed under the control of the nation whose captives they have become. The Journal publishes in this issue an article by Dr. Alonzo E. Taylor, professor of physiologic chemistry in the University of Pennsylvania, whose work formed the basis for the two noted reports to the American embassy at Berlin on the conditions existing among prisoners of the allied nations in Germany. This article on the feeding of war prisoners in Germany is especially timely. It is unusual because its point of view is broader than that of medicine, broader than that of science alone—in fact, as broad as humanity itself.

INTRAPERICARDIAL PRESSURE AND THE CIRCULATION

It is generally understood that one of the functions of the pericardium, if not its chief importance, is to check an excessive dilatation of the heart that might follow a pronounced rise in venous pressure which leads to the filling of the organ. Overfilling of the heart is prevented. Undue accumulation of fluid and rise of pressure within the pericardial cavity in turn produce a mechanical effect on the functions of the heart which may result in changes in arterial pressure. According to Kuno,[1] a very small amount of fluid in the pericardium causes diminution in the output of the heart. By further addition of fluid the output diminishes regularly. The arterial pressure changes only slightly until the amount of fluid in the pericardium reaches a certain limit. Beyond this limit the addition of a small amount of fluid causes a distinct fall of arterial pressure. The height of intrapericardial pressure which brings the circulation of blood to a standstill is just the same as that of venous pressure. If the venous pressure is raised during the standstill of the circulation, the blood flow is restored. In order to secure a recovery of the heart's action and circulation under a high intrapericardial pressure, therefore, it may become desirable to raise the venous pressure. This cannot well be done by injection into the veins. Kuno notes that an infusion of a large amount of blood causes no rise of venous pressure nor dilatation of the heart, or only a brief one. Such an infusion is therefore of no advantage to the circulation when this is hindered by pressure of fluid surrounding the heart. The intrapericardial pressure may sometimes be decreased, however, by the use of epinephrin; for this can diminish the volume of the heart and affect the organ favorably when it is compressed by fluid surrounding it.

THE BLOOD IN THE LUNGS

The capillaries of the lung are capable of great passive variations in capacity. This fact enables the lung to act as a sort of reservoir for one side of the heart. Any excess of output on the right side that cannot be dealt with promptly by the left heart is temporarily taken up by the wide lung capillaries, which offer very little resistance. Some idea of the extent of these variations is given by the current textbook statements. Thus, whereas at the height of inspiration the blood contained in the lungs is about one twelfth of the whole blood in the body, this amount is diminished during expiration to between one fifteenth and one eighteenth, and by forcible artificial inflation of the lungs may be lessened to one sixtieth.[1] In a recent experimental reinvestigation of the content of blood in the lungs in animals, however, Kuno,[2] of the Japanese Medical School at Mukden, has found that the amount is much larger than earlier authors have recorded. It varies from 9 to 19 per cent. of the total amount of blood. The amount of blood in the lungs increases with the acceleration of the circulation, that is, the amount of blood is about 2.2 times larger when the circulation is fast than when it is slow. When the lungs are edematous they may contain about one quarter of the whole blood, although the circulation is very slow. The time needed for the blood flow in the lungs is also more than twice as great when the circulation is slow than when it is fast. These observations, says Kuno, agree well with the necessities of life, since the amount of blood which comes in contact with the alveolar air may be directly proportional to the rapidity of the blood flow, or even increase in a higher ratio.

HUNGER AND APPETITE IN FEVERS

As has been pointed out at various times in THE JOURNAL,[3] the mechanism of hunger can now be studied in a purely objective way, in large measure independent of the impressions of the subject. The pangs of hunger are associated with rhythmic contractions of the walls of the empty stomach, and are presumably due to them. These movements can be recorded graphically by suitable instruments; the time of their occurrence, their intensity, and the factors that modify them in any way can be ascertained with the precision that belongs to modern scientific method. Impulses started by the gastric contractions are carried to the higher nervous centers, where they are recognized in normal consciousness as hunger. Appetite is not the mere sensation of pain from hunger contractions. It involves a psychic factor distinct from these physical changes, and concerns the memory of past experience with palatable foods. The clinician frequently observes conditions in which there is more or less complete loss of appetite and an absence of the pangs of hunger. This is especially true in the course of infectious diseases and in various acute exanthems. The absence of a compelling desire for food not infrequently offers a serious obstacle to the attempt to induce adequate nutrition. The reason for the loss of appetite has not been apparent, and at best the explanations commonly furnished are mere platitudes of vague hypothesis. In many instances the conditions that lead to an absence of hunger and appetite are associated with fever and the production of bacterial toxins. At the physiologic laboratory of the University of Chicago, Meyer and Carlson[4] have attempted to ascertain whether or not the elevation of temperature itself produces any effect on the hunger contractions of the stomach. Their observations by the use of the graphic method on gastric motility indicate that there is an absence of hunger contractions and a lowering of the stomach tonus during fever in dogs when the temperature reaches 103 F. and above, this being especially true in the temporary fevers. The temperature elevation itself is a factor in the depression of the stomach tonus and an inhibition of hunger contractions. Bacterial toxins, namely, paratyphoid, *B. prodigiosus*, and tetanus and diphtheria toxins, have no direct action on the contractions of the stomach musculature. The fever or the toxins appear to induce a lowering of vagus tone, on which in part the hunger contractions are believed to depend. But Meyer and Carlson do not believe that this will account for the absence of hunger during a fever lasting from ten to twenty days. The fact that external heat itself has, as they showed, a depressing effect on gastric hunger contractions is regarded by the Chicago investigators as significant with respect to gastric motility. Thus they say that the gastric derangements in young infants with the onset of warm weather may be due in part to the heat factor itself. It is conceded, of course, that the gastric enzymes and the food play a part in the disturbance.

Luxury in Sanatorium Management.—Among the blots on the history of sanatorium operation in the past has been the tendency to expend large sums of money on the elaborate equipment of quarters for officers, physicians, nurses and employees and to give to the officers the choice rooms and the choice locations in the grounds and buildings. The quarters for physicians and employees should be comfortable and adequately roomy, but the best outlook, the best location, the choice of accommodations, if there be a choice, should be given to the tuberculous patients for whom the institution is primarily intended. The pretentious luxury of officers' quarters in some public sanatoriums has been a lasting disgrace to those institutions and to their creators.—G. T. Palmer, in Illinois *Health News*.

Medical Mobilization and the War

THE MEDICAL OFFICER

Between the living and the dead the Army surgeon stands,
And life, oft hanging by a thread, lies in his skilful hands;
A soldier at his country's call, he draws no faltering breath,
But fights that mightiest foe of all, the final victor Death!

To meet so dread a foe he brings the true physician's mind,
Which holds, above all other things, the reverence for mankind:
Did his own brother wounded lie, tho' toward him he would speed,
He would not pass a foeman by, if his the greater need.

Within his breast, to duty true, no shrinking spirit dwells,
Oft has he served, and fallen too, beneath the screaming shells;
The hope to succour and to save, his one ambitious thought;
If honors come to mark the brave, they come to him unsought.

To snatch from ravening Death his prey with dauntless soul he speeds,
And few the words he has to say—his pity speaks in deeds!
The life within him, tense and clear, from brain to finger runs,
Nor does he heed, nor even hear, the roaring of the guns!

This son of science, rarely found applauding crowds before,
For whom no trumpet-blasts resound, too many oft ignore;
Yet he, upon the storm-swept plain intent alone to save,
And wounded scorning all his pain, is bravest of the brave!

—R. H. G. Osborne.

PLASTIC SURGICAL SCHOOL OPENED

The school of plastic surgery recently created by the Surgeon-General was opened at Washington University, St. Louis, October 15, with twenty-six students. Prof. Robert Terry is superintendent of the school and is assisted by officers detailed by the Surgeon-General.

BUREAU OF MEDICAL SERVICE ESTABLISHED

A new medical bureau known as a Bureau of Medical Service of Foreign Commissions has been established by the American Red Cross to meet the call for medical and surgical supplies for the Red Cross commissions in France, Russia, Italy and Serbia. Dr. Richard M. Pearce of Philadelphia is director of the bureau. This bureau will attend to the sending forward of physicians and nurses as required. Drugs and medical supplies to the value of more than half a million dollars have already been shipped to Russia; three detachments of child welfare specialists have been recruited for service with the new Children's Bureau of the Red Cross in France, and the bureau is also furnishing bacteriologists and chemists and other needed personnel for the Red Cross establishments in Paris.

NEWS OF THE TRAINING CAMPS

Colored Medical Officers' Training Camp at Fort Des Moines

The opening of this medical officers' training camp at Fort Des Moines, Iowa, marked a new departure in the policy of the Medical Department of the Army. Heretofore, except in a few isolated cases of medical officers in colored National Guard organizations, the colored medical officer did not exist. With the establishment of a colored division of the National Army, the need for trained medical officers became urgent. Already there were 1,200 colored men in training at the reserve officers' training camp for service with the infantry of the National Army. Among these were about thirty physicians. These were later transferred to the medical training camp and commissioned in the medical section of the officers' reserve corps.

With the men transferred from the line camp as a nucleus, the school was started, August 27. Soon there were 116 men in training. Of this number, twelve are dentists. These officers come from all sections of the country, as far west as California, as far south as Texas and Louisiana, as far north as Maine, and as far east as Massachusetts. They represent nearly every reputable medical school in the country, Harvard, Northwestern, the Universities of Michigan, Southern California and Pennsylvania, Columbia University, Howard, Meharry and many others, including two schools of homeopathy. A large proportion are hospital trained men, fourteen having served internships in one hospital, Freedmen's, a government institution at Washington, D. C.

With Lieut.-Col. E. G. Bingham, M. C., as commandant, and Majors H. C. Maddux, M. C., and T. Victor Keene, M. R. C.; Captains Morrill, M. R. C., and Axline, M. R. C., and Lieutenants Coates, M. C., and Gatewood, M. R. C., as assistants, intensive training in military discipline, drill, Medical Department "paper-work" and administration was begun. Parallel to the officers' training camp there is a training camp for enlisted men of the Medical Department. There are now in the latter camp about 900 men.

The general plan of the course of instruction was similar to that employed in the other training camps. The routine program has been interrupted from time to time with short hikes for practical work in field sanitation. The excellent and extensive system of trenches constructed on the fort by the student officers of the line camp afforded considerable opportunity for practical work in trench sanitation, and in the care and evacuation of the sick from the first line trenches to the rear. In field problems and map reading and drawing, the terrain of the reservation offered interesting situations.

The most pretentious single incident of the camp was the four day demonstration hike in charge of Major H. C. Maddux, M. C. This hike was started Wednesday morning, October 3, and lasted through to the following Saturday. The whole camp marched from Fort Des Moines through the city of Des Moines to the Iowa State Fair Grounds, a distance of 9 miles. The camp was officially designated "Camp Bingham." The marching column consisted of the instructors mounted, followed by the troops in full marching equipment, with a section of litter bearers. A pack train of ten pack mules with full medical combat equipment followed, and the rear was brought up by a squad of military police.

The marching column swung along the country roads and city streets singing and whistling "Tipperary," "Are You From Dixie?" and many other songs dear to their hearts. The march was made in three hours, and not a man fell out; on the arrival at "Camp Bingham" there was not a sore foot. Three motor trucks loaded with field ranges and cooking utensils preceded the marching column, and within half an hour after tents were pitched a hot meal was served to the weary, yet happy men.

The specific duties were so rotated at the camp that each section had instruction in the various activities of field service, camp infirmary work, pack train detachment duties, sanitary squads and military police. Each day a part of the command was taken to the nearby fields and instructed in the establishment of first aid stations, camp infirmaries, litter bearing on the battlefield, and the application of first aid measures. Especial attention was given to instruction in the rapid and careful evacuation of the wounded to the rear, also in the rapid moving of the first aid station. One detachment completely packed the combat equipment on the pack mule in four minutes and fifty-five seconds, and half an hour later set up the first aid station in less time.

The nights spent at the camp were cold and frosty, and the physicians, old and young, fresh from the comforts of modern civilization, found scant comfort resting on the bosom of Mother Earth, covered with two thin blankets. Officers, like enlisted men, carried their entire equipment in blanket rolls on their backs; for the sake of the experience their bedding rolls were left at home. After the first night by rustling straw, hay, leaves and newspapers on which to make their beds, the succeeding nights were spent in greater comfort.

Each night huge camp fires were built, and around them crowded the shivering civilian physicians of yesterday. The early part of the night was spent around the camp fire with tales, songs, prophecies and longings; longings to do their bit in the war and return to their families and firesides.

On the morning of October 6, reveille was sounded at 4:30, and preparations for marching back to the fort were begun. The march was to start at 7 o'clock. At this hour every tent had been struck, grounds policed, and officers and soldiers alike stood awaiting the command "Forward—March."

The camp has not been neglected by distinguished visitors. September 18, Colonel Noble, M. C., visited the camp and reviewed the troops as an official representative of the Surgeon-General. His visit was followed by Colonel Legarde, M. C., who delivered a lecture on the "Newer Developments in Military Surgery."

October 15 was memorable because it marked the closing of the "line officers' camp" and the coming of many distinguished visitors. During the day we were given a very inspiring address by Mr. Emmett J. Scott, former secretary to the late Booker T. Washington, and now special assistant to the Secretary of War. Later in the day we were reviewed by Colonel Munson, M. C., Chief of the Medico-Military Division of the Surgeon-General's Office; Colonel Goodwin, R. A. M. C., and Colonel Charles Dircle of the French Army Medical Corps. So impressed were the latter visitors with the camp that at great personal trouble and inconvenience they returned, October 20, for another visit. During this visit we were given a short address by Colonel Munson, and a lecture on "Sanitation in the Trenches" by Colonel Goodwin. That evening we were given an illustrated lecture by Colonel Dircle of the French Army Medical Corps on "Medical Activities on the French Front." Monday evening, October 22, we were shown "The Activities of Our Medical Corps on the Mexican Border" by Colonel Bingham, in moving pictures.

The purely professional instruction has occupied the latter part of the course. We have had practical demonstrations and moving picture clinics in orthopedic surgery and in the treatment of infected wounds by the Carrel-Dakin method of wound sterilization.

The spirit of the camp epitomizes the spirit of the entire colored race in America, in its deep earnestness and desire cheerfully to do its bit in making the world safe for democracy.

At Fort Benjamin Harrison

CAMP GOSSIP

The chief interest of this camp centers around the permanent assignments of medical officers to various stations in this country and abroad which are now being made.

The conditions in the camp are good, notwithstanding the disagreeable, damp, cold weather. The barracks have been made comfortable by stoves, for which the quartermaster supplies an abundance of coal. One can readily understand that he is not generous enough to supply janitors to build and keep these fires going. That work is done by the orderlies who are detailed daily from among the medical officers.

The principle of learning to care for oneself, which is included in the course of instruction, is beautifully illustrated by the above-mentioned task. These things are all part of the work, and to show how well they are "playing the game" is the fact that, besides acting as janitors, the entire policing of our section of the camp is being done by its members. Not the least of these duties is that of keeping in order the long stretches of intersecting cinder paths which have been laid. Heretofore this policing work has been done by the enlisted men of the field hospitals, who have been in training here. Most of such troops, however, have completed their training and have been sent into active work away from this camp, leaving it to the medical officers to do their own work.

The rumor is abroad that the camp will close at the end of November, and in consequence the work of prepartion is being intensified. Instruction in trench warfare, as it applies to the sanitary troops in actual campaign, is given great importance.

TWENTY-FOUR HOURS IN THE TRENCHES

A number of squads, consisting of twelve medical officers, eleven acting as medical corps men and one as captain, are given a tour of duty of twenty-four hours in the trenches. They participate with troops from all other branches of the service, there for a like purpose, in actual night and day battle maneuvers. Each man of these sanitary squads is equipped with all of the latest paraphernalia for such service, and is obliged to carry out in detail the duties of the position to which he is assigned. Of course, when the medical officers reach France or any of the other battle fronts, they will not perform the duties which are imposed on them as here described. They must be taught, however, what is to be expected of the men whom they will later command, and will learn this the more readily by doing it themselves. Hence in this work at this time they are acting as enlisted men. They are equipped as such on these tours of duty, are rationed as such, and also quartered as such, sleeping in a niche in the trench or on the hard planks in the dugout, curled up together to keep warm. They go "over the top" into "No Man's Land," and drag in the wounded just as if they were in actual battle. In this way they learn the possibilities and the limitations, and thus will be in a position to know what may be got out of their men in the future.

"You ask me about my night in the trenches," said Dr. E. W. Ill of Newark, N. J. "It was very interesting indeed, and I will try to tell you what it was like. At roll call in our company, twelve names were read off for this duty, and I noticed that all of the men chosen were under 30 years of age. These twelve were highly elated at being able to have the experience. We were marched, with Seng, one of our number, in command, to Lieutenant-Colonel Shockley, who told us to get our equipment at the medical supply headquarters, and then our blankets and rations. We each received as equipment a knapsack with a myriad of straps, cords, pockets, etc., and a belt with about twenty little packets of many first aid articles—bandages, cotton, gauze, adhesive plaster, etc. The belt also had many little holes in which to hang the hatchets, canteens and other parts of the equipment. For these things we signed a voucher, making us responsible for their return, as the government is very careful of its possessions.

"Before leaving camp we rolled into our blankets a heavy sweater and an Army slicker, and did it neatly for fear of summary punishment if we did not have it right. We received rations for three meals, consisting of six huge ham sandwiches, two hard-boiled eggs with salt, two bars of milk chocolate, a dozen sweet crackers, an apple and an orange, and we filled our canteens with ice water. We put on our heavy woolen underclothes and our trench coats and shoes, and at last got inside of all the other equipment—haversacks, hatchets, canteens, etc.

"At promptly 3 o'clock in the afternoon we collected our six litters, formed three groups of four men each, and began our 2 mile hike to the trenches, as we thought, heavily laden. On arriving there we found that our packs were about 20 pounds lighter than those of the enlisted men of the line. We reported at battalion headquarters, where two of us were left as reserve. The rest were immediately taken into the trenches, where we were given instructions on our duties, and informed that we would go in promptly at 7. While waiting we finished a part of our rations, with some water from our canteens, spread out our litters, took our blankets and sweaters from our packs, and lay down. It was getting cold and beginning to rain. Three or four large companies of the line, in single file, fully equipped, marched by, not a word being spoken except a muttered oath when some one or other stumbled over a tree stump, as there was no light. At 7 we started, but lost our way once, when we got into a drainage ditch instead of the trench, but at last hooked up with the sergeant, and were led to the first shelter, where, with the aid of a pocket light, we found a comfortable hole in the wall, and wrapped up in our blankets and went to sleep. It was so nice and snug that we almost hoped the sergeant would not find us. He did, however, and we were routed out and proceeded along the zigzag communicating trenches until we got to Shelter No. 5, where we were to spend another two hours. Desultory firing was going on all the time, and a few rockets, which were very pretty, were let off, but no wounded were brought back. Two of us tried to sleep on one litter and accordingly got nothing but crossbars for a resting place. It was becoming much colder, and we were also getting more uncomfortable all the time. At 11 we were aroused again to traverse some more zigzag trenches through the mud and water, until we reached Shelter No. 1, at the front. Here we found two bunks, each about 9 feet long, one above the other, on which we attempted to get some rest. Time dragged on and we had almost given up hope of ever having anything to do when, at 12 o'clock sharp, a great noise informed us that a battle was going on. The sergeant poked his head in and yelled, 'Mac and Ill, there are some wounded to be brought in.' We scrambled out, leaving our blankets behind, and crawled over the top and out to look for wounded. It was very cold by this time, and the ground muddy and soggy, but we knew better than to get too high up, as the combatants were armed with paraffin bullets which some of our companions said 'stung like H——.' I finally encountered a body and said, 'Are you alive?' The man said, 'Yes, but badly wounded in the leg.' I told him to put his arms around my neck and I would drag him in. It was pitch dark, and we encountered rocks, mud, etc., en route, which was, to say the least, disagreeable. At last I saw the sandbags of the top of the trench and thought, 'Well, I will be safe from firing now,' when a flare went up, followed immediately by a fusillade of shots from the 'Germans' at the wounded man and myself. One hit me a stinging blow in the left leg, and I cussed a few times and told my wounded companion to 'scramble for himself.' He did, and we gained the trench without further mishap. The other men of our squad had similar experiences, some being hit in several places. When I got the man back I bandaged up his leg and we transported him to the rear, my own wounds being left undressed. My two other trips were unaccompanied by rifle fire, and I even had time to wrap up and get a little more sleep out in "No Man's Land," safe from the scrutiny of the ever-watchful sergeant.

"Without this actual experience I could not possibly have had other than a vague idea of the duties involved, together with the hardships to be expected. It is needless to say, and I am sure no one will accuse me of being a quitter when I do say it, that I am more than elated that duty in France for me will not be that of the enlisted man of the Medical Corps whom I represented in the battle just described, who goes out not only exposed to infantry fire and bombs, but without any protection whatever. His is the most dangerous work of all, as he is exposed to the fire from both sides. In fact, one of the squads reported on its return that its own first sergeant had been shot twice by our own guards because he was too frightened to halt when ordered to do so; while two other men lost their bearings completely and wandered too far over, where they were captured by the 'Germans.'"

TRAINING CAMP ACTIVITIES

The Commission on Training Camp Activities, appointed last April by the Secretary of War, has issued in pamphlet form a summary of its activities to date. The object of this commission, as stated in the pamphlet, is to supply the normalities of life to a half million young men in the training camps and to keep the surroundings of these camps clean and wholesome. The task is to furnish these young men a substitute for the recreational opportunities to which they have been accustomed, and to prevent and suppress vicious conditions which may arise in connection with the training camps. To carry out these activities the commission is enlisting the services of such existing agencies as the Y. M. C. A., the Knights of Columbus, the Playground and Recreation Association of America, the Travelers' Aid Society, the Young Women's Christian Association and many others. The American Library Association has undertaken the important task of furnishing books, magazines and general library facilities as well as trained librarians for the camps. A special library building is planned for each camp. Recreative athletic work has been placed in charge of a director, and supervision of the work in each camp will be looked after by an official athletic council. The manly art of boxing will be included, and the services of such disciples of the fistic art as James J. Corbett and "Kid" McCoy have been enlisted. Baseball and other athletic games are also provided for. Post exchanges for soldiers, and cooperative stores have been established in each camp. Camp music has been planned, with song leaders, and the singing of songs is especially to be emphasized among the soldiers. A song book, "Songs of the Soldiers and Sailors," has already been published. Dramatic entertainment will also be provided. A fully equipped modern theater building seating 3,000 is being erected at each of the national camps. The organization of programs for these entertainments has been placed in the hands of leading theatrical managers of the country, and the best talent will be employed. The Redpath Entertainment Bureau has already been giving entertainments in the various camps. Educational work has not been neglected. There will be courses in English, French, French geography and other subjects, and an educational campaign in sex hygiene through the agency of the American Hygiene Association and the Y. M. C. A. There will also be a considerable degree of supervision over the recreational activities of the soldiers in the cities and towns adjoining the camps. With the aid of many state (public and semi-public) agencies, the control of prostitution in the neighborhood of the Army camps has been attacked, and already important results have been accomplished in the way of the abolition of "red light districts" and the supression of vice in many of the cities surrounding the Army camps. The personnel of the commission is as follows: Raymond B. Fosdick, New York, chairman; Lee F. Hanner, New York; Thomas J. Howells, Pittsburgh; Marc Klaw, New York; Joseph Lee, Boston; Malcolm L. McBride, Cleveland; Dr. John R. Mott, New York; Charles P. Neill, Washington, D. C.; Lieut.-Col. Palmer E. Pearce, U. S. Army, and Dr. Joseph E. Raycroft, Princeton University, with Jasper J. Mayer, secretary to the commission. The funds to support this great work will come from private subscription through the organization named, from various state, municipal and other organizations in the extension of their regular lines of work, and in some instances from government grants in the way of salaries, etc. Some of the entertainment features are expected to be self-supporting through nominal admission charges. The Navy Department has a similar commission, of which Mr. Raymond B. Fosdick is also chairman. A report of the latter commission is soon to be issued.

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

With the arrival of 10,000 drafted men, the amount of sickness has greatly increased, especially measles. Measles had existed in all regiments for a year continuously. The draft men brought in cases on every train. Fortunately there have been almost no complications or sequelae.

The camp is being visited almost daily by the officers or agents of various committees and organizations interested in the welfare of the Army. Some of these bodies are of real value; others of the visitors never accomplished anything more than making reports.

Pneumonia is the disease of the camp. Fifty-one patients have entered the hospitals, with three deaths to date. Many of the patients are by no means out of danger. The strength of the command has passed the 21,000 mark. The commissioned personnel of the division is now in excess of authorized strength. The enlisted personnel is 75 per cent. strength.

A reception and luncheon was given by Mrs. Charles Holt in Macon for General Steiner, Major Weeden, M. C., and others, Wednesday evening. Many from the camp attended.

Lieutenant Miner of the Sanitary Corps addressed the officers at the medical school on the subject of vice suppression, Thursday. Vice suppression is a live question in this camp. Macon is not at all clean, and there is much venereal disease. Captain McCampbell, M. C., of the Surgeon-General's Office, was also here working along the same lines.

ONE HUNDRED AND SIXTH SANITARY TRAIN

In the assignment of new officers of the Medical Reserve Corps just arrived from the medical officers' training camp, Fort Oglethorpe, the complement of all companies is now complete. Wednesday afternoon, a field problem on a small scale was planned by the division surgeon and carried out with fair success. The participating units were the Sanitary Detachment of the One Hundred and Eighteenth Field Artillery, under Major Taylor, who performed the duties of the regimental surgeon; the Florida and Georgia field hospitals, which furnished sixty men, acting as patients; and Ambulance Company No. 122, under Captain Blackwell, which established the dressing station and evacuated the wounded from the regimental collecting station by litter to the dressing station, and thence by ambulance to a theoretical field hospital established at the camp. While many rough edges were noted and much to criticize was found, all felt that the afternoon was profitably spent.

The weekly social of the officers of the train with ladies was held, Hallo'een. The party took the form of a dinner-dance, dinner being served at 6 o'clock in the mess hall of the One Hundred and Twenty-First Ambulance Company which was very prettily decorated with autumn foliage.

An interesting lecture was given by Lieutenant Miner of the Sanitary Corps, Thursday afternoon, November 1, on the work being done in repression of vice in the cantonment zones.

Many of the officers of the train, with ladies, attended an invitation dance given by the officers of the One Hundred and Twenty-Fourth U. S. Infantry at the Hotel Dempsey, Saturday evening, November 3.

Fortunately the train has so far escaped the outbreak of measles that has been so evident in other sections of the camp. We are "tapping wood."

Seventy-Seventh Division, Camp Upton, Yaphank, N. Y.

The medical work in this cantonment has been dominated during the past two months by the physical examination of the men of the National Army. These men have reached the camp in increments of at times from 2,000 to 3,000 in a single day, and orders have required that this entire number should be examined, and their necessary papers made out in one day so that they might be examined, mustered in, assigned to organizations and in uniform the third day after their arrival, inclusive. The amount of stress imposed on the medical staff by the rapidity of this work has placed a severe tax on both officers and men and has obligated to a certain extent relative neglect of other work, such as regular drill and instruction.

The camp has been singularly free from serious infectious diseases. Measles, which has been and still is one of the most serious contagions in military encampments, has been present, but ten cases only have occurred, eight of which occurred in a single organization and apparently from a single focus of infection. No secondary cases have as yet developed, and at present a single patient remains in hospital convalescing. No diphtheria cases have been discovered and yet the Schick test which was applied in about 3,000 instances showed the usual percentage of susceptibility to this disease. One man with pertussis entered the camp with an increment of the National Army, but there have been no secondary cases. One case of mumps only has been reported and there have been no instances of either typhoid or paratyphoid fever, though sporadic cases were fully expected. Examinations for carriers are under way, but thus far results have been fortunately negative.

Owing to the fact that the base hospital unit is still building and untenantable, this institution has been housed in ordinary barracks, frequently moving from one to another as they have been displaced by the military organizations normally assigned to these buildings. Within the next ten or fourteen days it is expected that the most essential buildings of the base hospital will be in such condition that a last move may be to this unit of over seventy buildings which in every way is ideally adapted to the needs of the service. The buildings, although hastily constructed, are well made, conveniently arranged and equipped with practically every convenience to be found in the most modern civil hospitals.

A regular course of lectures and instruction on military medicine has been started under the supervision of Lieutenant-Colonel Reynolds, the division surgeon, and additional arrangements have been made for clinical demonstrations, papers and lectures by the various departments of the hospital. Regular sessions of a base hospital medical society under the direction of Major Jay Whitham, commandant of the base hospital, have been projected, and in addition to the work presented by the various members of the staff, members of the profession from New York City and elsewhere will be on our programs. The regular meeting of the medical section of the New York Academy of Medicine in New York City was given over to the staff of the Upton Base Hospital on October 16, and by invitation of the president of the New York Academy of Medicine the program of the February open meeting of the academy will be given by members of the various staffs of this hospital.

The members of the dental staff at Upton are holding regular meetings of a dental society in which the program and clinics are given both by members of the local staff and by outside talent. The location of this camp, so accessible to New York, has made it possible to keep these activities of a very high scientific grade. The hospital library will include all modern standard textbooks and all the current native and foreign journals will be at hand.

Eightieth Division, Camp Lee, Petersburg, Va.

There are now 175 medical officers on duty at Camp Lee, only three of whom are of the regular Medical Corps, Division Surgeon Lieut.-Col. Thomas L. Rhoads, M. C., Division Sanitary Inspector Henry P. Carter, M. C., and Major Ferdinand Schmitter, M. C., commanding officer of the base hospital. Fortunately for these three medical officers and the welfare of the Eightieth Division, nearly all of the 175 medical reserve officers have had training at one of the medical officers' training camps, the greater number of them having been at Camp Greenleaf, Ga. The training there was of great assistance, though a marked change in the character of the work took place at Camp Lee. Lieut. S. W. Tunnell of Philadelphia describes his first few days quite graphically:

> At 8 a. m., I received orders to report to Colonel ——, at depot brigade. At 8:30 I reported, and was instructed to be prepared to examine three battalions, 1,800 men that were expected at noon, in just three hours and a half. Note.—Absolutely barren, unfinished buildings, supplies at 2 miles' distance, roads muddy to the junction of the lower to the middle third of leg, no transportation.
>
> 10:30 a. m. (two hours later): "Sir, we are prepared to begin examinations." On receipt of order assigning me as surgeon to the depot brigade, I walked for one-half hour through the most affectionate mud that one could imagine and located my commanding officer. Lieutenant, "Reporting for duty, Sir." Six little words were all that I volunteered to exchange for the following volley fired after one squint at a little note book. "You are assigned to me as senior surgeon. You will have as your assistants [here he named two other medical officers]. We expect 1,800 men at noon today and you must be prepared to examine them. There is the infirmary over there [pointing to a two story wooden building]. It is absolutely empty, in fact it isn't finished, and there is no equipment available. You may borrow, beg or steal (borrowing without knowledge of owner), but you must be prepared to begin examinations at 12 o'clock."
>
> There was not the slightest doubt in my mind that the colonel meant just exactly what he said. I then conversed two more words, "Yes, sir," saluted and departed. About that time the other two officers reported and we were off. In five minues we had twelve empty nail kegs which we officially took as office chairs, sent one officer to the medical supply depot, a mile and a half away, for triple typhoid vaccine, smallpox vaccine, and an emergency recruiting outfit. We sent another officer with a requisition for stationery supplies to the quartermaster 2 miles away. This left four officers. Two gas pipes immediately became hammers, nails became plentiful when a dental surgeon eased a carpenter's toothache by plugging a cavity with a piece of cotton from a nearby field with a nail. In fact, that is how we learned where the nails were. Scrap boards spontaneously jumped into table tops and a leg flew on each corner. We walked through the officers' quarters, and as there was no one at home, we borrowed two more tables and two benches. We found a tomato can and made a half pint of ink with some ink tablets which an officer carried for his fountain pen. We found a plumber working close by with a foreign body in his right eye, and while I was removing the particle some one of the officers borrowed a dozen plugs for gas pipes from his kit, which we used for ink wells. To our fountain pen brigade we added a dozen penholders made with a penknife from sticks in case there were no others available. We gathered some more cotton from the field and stole a cake of soap to cleanse the arms from vaccinations. We telephoned to an ambulance company to borrow twelve enlisted Medical Department men to use as clerks and help run the infirmary. About this time one of the officers returned from the medical supply depot with our vaccines, recruit outfit, cotton syringes, eye card and finger print outfit. The other officer returned with real stationery, and we then proceeded to consolidate the ground that we had gained. In two hours' time we had generated our equipment from nothing and established a system which later examined 329 men in one day.
>
> The draft men did not begin to arrive until about 5 o'clock in the afternoon, when we immediately examined for contagious disease. The physical examinations we postponed until morning because we had no lights. Our borrowed enlisted Medical Department personnel arrived that night. We drew their beds from the supply officer and had them attached to the battalion for mess. Each man immediately became a clerk, assigned to their desks and instructed in their work. The following morning our complete force reported for duty at 7 o'clock, and the wheels of a polished system began to grind out examinations.

FIELD HOSPITAL NO. 318

This company was organized, July 1, 1917, in the medical officers' training camp at Fort Oglethorpe, Ga., by Lieut.-Col. R. L. Carswell, M. C., provisional director of field hospitals, and was placed in charge of Lieutenant Comfort, N. G. Conn., assisted, after July 10, by student commissioned officers. Capt. Elliott B. Edie, M. R. C., was made commanding officer, August 6, and the commissioned personnel completed by assignment of Capt. William D. Hunter, M. R. C.; Lieut. J. H. Boyles, M. R. C.; Lieut. L. F. Boland, M. R. C.; Lieut. M. I. Mendeloff, M. R. C., and Lieut. P. J. Bean, M. R. C. The enlisted personnel was received from the recruit camp.

A field hospital with its horses and wagons, fourteen tents and field kitchen looks so much like a Wild West show that the observer instinctively looks for the Indians and the Deadwood stage coach. The company participated in two reviews during the last week of August. These were regarded as part of the graduation exercises of the medical officers' training camp, and every officer and enlisted man marched past the reviewing officers with a feeling of pride that he was a member of the first class to graduate from Colonel Page's university. Field Hospital No. 318 entered the National Army cantonment at Camp Lee, Va., August 27, being one of the few organizations with an enlisted personnel. The company was called on for details of men for special duty, varied in kind, but all a part of the great task of preparing for the reception of the selected men. This work now being completed, the "details" have been returned and the reunion of the company was celebrated in the company mess rooms on the evening of October 25. Short talks were made by the officers, and a musical entertainment was given by the men. Announcement was made of the final result of the Liberty Loan campaign. The per capita subscription of the company was $81, nearly $20 more than Camp Lee's average. It is expected that the sanitary train will be completed about November 1 by the organization of three field hospitals and one ambulance company, with officers from Fort Oglethorpe and men from the depot brigade. The officers and men of the Three Hundred and Eighteenth look forward with pleasure to a resumption of regular training in the duties of the sanitary soldier, and hope to be of service in the instruction of the new companies.

AMBULANCE COMPANY NO. 319

This organization, now a unit of the Three Hundred and Fifth Sanitary Train, Eightieth Division, had its origin in a persistent and insistent appeal of Richmond chapter, American Red Cross, through its president, at the time Henry W. Anderson, now in charge of the Roumanian commission. This appeal thus forcefully made to the headquarters of the American Red Cross at Washington during the earlier part of July received favorable consideration, and, July 10, authority was granted by Lieut.-Col. C. H. Connor, in charge of the organization of all the Red Cross ambulance companies, to Richmond chapter to form and equip a unit, to be known as the Red Cross Ambulance Company No. 46.

Pursuant to an order from the division surgeon, in accordance with instructions from the Surgeon-General's Office, October 15, numbering of the ambulance company was adjusted. No. 46 ceased to be, and the number 319 was given. The officers of the organization were chosen with the object of furnishing the command with men especially fitted to instruct the personnel along the lines that make for excellence in ambulance work. The commanding officer, Lieut. C. H. Lewis, is from Richmond. The junior surgeons are Lieut. George S. Hurt, Kentucky; Lieut. Julius J. Hulcher, Richmond; Lieut. Oliver C. Brunk, Richmond, and Lieut. Ray A. Moore, Richmond. The enlisted personnel is as diversified as it is remarkable intellectually. Great care was exercised in the selection of these men for this service, and as a result experts from every conceivable line of human endeavor can be found: mechanics, chauffeurs, carpenters, pugilists, lawyers, physicians, chemists, clerks, football artists; a fat man so fat that S. O. is necessary to outfit him; thin men so thin that they would have to suffer a fracture to reduce.

AMBULANCE COMPANY NO. 317

Ambulance Company No. 317 was organized as Red Cross Ambulance Company No. 43 of Raleigh, N. C. The original promoters were John G. Allen, Raleigh, N. C., and Kenneth R. Ellington, New York (a Tar Heel by birth). The former is now a first lieutenant in the Signal Corps, and the latter an ensign in the Navy.

The officers are Charles L. Scott, Sanford, N. C., University of Maryland, 1899, commissioned as First Lieutenant, M. R. C., June 8, 1917, and Captain, M. R. C., August 21; Vance P. Perry, M. C., Va., 1916, Kinston, N. C., commissioned First Lieutenant, M. R. C., in July; Dewitt D. Clark, Clarkton, N. C., commissioned First Lieutenant, August 1, and Neil G. Nicholson, M. C., Va., 1917, Mount Gillead, N. C., commissioned First Lieutenant, Sept. 1, 1917.

The volunteer enlisted men are from middle and eastern North Carolina, and range in ages from 18 to 40, representing some of the best blood and oldest families as well as individual specimens of manhood and intellect.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

Seven companies of the Three Hundred and Thirty-Sixth Infantry are quarantined on account of measles. Hundreds of relatives visited the camp, Sunday, but were unable to get closer to the barracks than to talk to the men across a little ravine back of Company F's quarters. Several thousand visitors, many bearing flowers and edibles for the sick soldiers, visited the base hospital. Four cases of cerebrospinal meningitis have been reported from the regiment. The medical detachment of the regiment under the command of Capt. C. C. Osborn is working night and day to stop the epidemics of measles and meningitis. Lieut. J. D. Holston daily examines more than 2,000 men, looking for suspects. Lieuts. Samuel R. Laubscher and Charles H. Davis are kept busy with a corps of men spraying the throats of every man in the regiment to prevent infection.

The office building and barracks which have been constructed for the use of the British and French officers detailed to the camp were completed last week.

Physicians, social workers and laymen interested in the treatment of social questions met at the Seelbach Hotel, October 31, to discuss steps to be taken for the prevention and treatment of venereal diseases among the soldiers at Camp Zachary Taylor. The meeting was called by Edward H. Griffith, representative of the War Department. One of the chief speakers was Col. John H. Allen, division surgeon, who told of the work already done by the authorities at the camp toward the suppression of disease, and Major L. D. Frick, who urged the reporting of vice diseases by physicians.

Col. S. B. Pearson holds the record for rapid promotion from Captain to Lieutenant-Colonel since arriving at Camp Zachary Taylor. He is a cavalry officer, twenty-two years in the service, and is camp quartermaster. Under his direct supervision is the camp bakery, in which the principal article of the soldiers' food is prepared. Every day the force under him bakes 10,000 loaves of white wheat bread, enough to feed 30,000 men three times a day. The ration allows each man a pound of bread a day, which it has been found is slightly in excess of the actual consumption. Once a week the student bakers prepare what is known as war bread, a loaf that has a heavy crust and weighs 4 pounds. This heavy crust has been found by the French to facilitate shipment, as it prevents breaking and crumbling.

BASE HOSPITAL ACTIVITIES

Mrs. Leonard Wood, wife of Major-Gen. Leonard Wood, and Mrs. Draper, of New York, were recent visitors at Camp Zachary Taylor, in the interest of the Red Cross. They expressed pleasure in finding the base hospital in such excellent condition. Mrs. Wood complimented the site on which the camp is located, and said she considered it an ideal place for the training of soldiers. They are visiting the army camps of the United States in the interest of the Red Cross.

The base hospital laboratory is now fully equipped, and it is doing excellent work. All patients with pneumonia are examined to identify the type of pneumococcus. In two cases the types have been identified as I and IV, and the appropriate serums used. An ample supply of white mice has been obtained for this work.

A most comprehensive plan of examination has been outlined of all the drafted men from eastern Kentucky for hookworm, with probably an examination of all of the Kentucky troops later on. This will be done under the supervision of Captain Fox. It is estimated that 200 specimens can be examined a day, and those men in whom hookworm is found will later be examined by Major Hamburger physically and by the psychologic board also, a careful record being made of each case.

A number of interesting cases are under observation in the base hospital. Several cases of cross-infections have been encountered. One man had a very severe discoloration of his skin from a catarrhal jaundice, and on the eighth day was admitted to the contagious ward with measles, presenting a measles rash of peculiar color. Another patient had mumps with a bilateral orchitis following, and later a typical typhoid. To this man two prophylactic injections of typhoid vaccine had been given. One man had a severe cardiospasm, with subsequent relief from esophageal dilatation. An officer was admitted with severe bleeding from a duodenal ulcer. The roentgen ray is being used to great advantage in all these gastric cases.

Owing to the number of cases of measles, four isolation wards have been opened. The following is a record of the severe cases in the hospital, November 4: meningitis, 4; measles, 94; pneumonia, 21; typhoid fever, 4; mumps, 12, and diphtheria, 1. Two perfectly well meningitis carriers have been found and isolated.

It is the purpose of Major Hamburger to have all tincture of digitalis used at the base hospital standardized on the cat by the method of Hatcher and Eggleston, and as outlined by Lieut. Willard J. Stone. This will be done by Prof. C. O. Zahner in the Department of Physiology of the University of Louisville Medical Department.

SPECIAL EXAMINING BOARDS

A board of psychologic examiners has been convened at Camp Zachary Taylor, which is one of the four camps chosen by the Medical Department of the Army for this work to be done in. The entire army here will be standardized by putting each man through certain physical and mental tests, so that they may be properly classified, artisans properly assigned, etc. More will be written of this work later. It is under the supervision of Lieut. Marion R. Trabue, S. C.

All of the men are now being examined by a special board of ten examiners for tuberculosis under the supervision of Capt. M. J. Lichty.

PERSONALS

Major Worthington has instituted food conservation in the officers' mess at the base hospital, meatless and wheatless days, and certain meals without butter. Those who help themselves to butter in quantities too bounteous, and leave some uneaten, are specially reported by the mess orderlies.

An order has been issued prohibiting officers and enlisted men from entering certain districts in Louisville, and has been read to each organization in camp. Any man found in these districts will be arrested by the members of the provost guard or military police. One of the unused city police stations has been equipped and used as headquarters for the military police.

Dr. Fred L. Koontz, M. R. C., spent a few hours in Louisville last week en route from Fort Oglethorpe to Philadelphia, to which city he has been ordered for a course of intensive training in head surgery at the University of Pennsylvania Hospital under Drs. Frazier and Spiller.

Dr. John B. Richardson has been ordered to Bellevue Hospital for a course in fractures.

Miss Helen Pond of Framingham, Mass., a dietitian, has reported to Major Worthington of the base hospital. She is a welcome addition to the staff of the hospital.

Lieut. James W. Bruce, M. C., Louisville, was married at 5:30, November 5, to Miss Edith Campbell, daughter of Mr. and Mrs. Charles D. Campbell, at Christ Church Cathedral. The wedding, originally set for December, was hurried because of Lieutenant Bruce receiving traveling orders.

Eighty-Fifth Division, Camp Custer, Battle Creek, Mich.

LIBERTY LOAN

The "Liberty Loan" proved of considerable interest from a competitive standpoint during the last week. The division subscribed $1,389,750. This figure is high, considering that the division is at less than half strength. The sanitary personnel of the division has accomplished a wonderful showing. Base hospital, $21,050; field hospital, $29,300; ambulance companies, $38,050. In the field hospitals, Field Hospital No. 340, under the command of Capt. J. D. McGaughey, showed the largest subscription average of $103 for each man in the company. The general average for all field hospitals was over $97 per man.

SANITARY TRAIN

The medical personnel of the sanitary train is now complete, so that the training of the sanitary troops is progressing rapidly. Although the rainy weather has in some respects handicapped outside work, it has in no way brought it to a complete standstill. The men seem to get along just as well in the rain as they do on clear days, due entirely to the unusual enthusiasm that seems to exist among them. It is not such a difficult task as one might expect in training these men in the duties of nurses, the operating room assistants and ward managers. They seem to grasp the subject pertaining to medicine and surgery very rapidly indeed and in quizzes seem to answer up as well as some medical students in their first and second years. There is no doubt that these men will be ready to fill the various places when the time comes for active service.

NOTES

Major Wood, commanding officer of the base hospital, read a paper before the Kalamazoo Medical Society, October 23, on "The Organization of the Base Hospital." His paper was exceedingly interesting and covered the matter thoroughly in every detail. The meeting was well attended, both by the members of the society and officers from the camp.——Majors Irons and Frick of the base hospital were in Chicago attending the meeting of the Clinical Congress.——Capt. W. P. Nicolson, Jr., of the 338th Ambulance Company recently spent two days in Chicago.

Eighty-Seventh Division, Camp Pike, Little Rock, Ark.

A recent order transferring enlisted men from this cantonment, in order to fill up the necessary quota in the National Guards of their respective states, has wrought temporary havoc with the enlisted personnel of the sanitary train. The present indications are that with the exception of the Red Cross ambulance companies and a small detachment of regular Army men brought here from Fort Riley, Kan., that the train will be compelled to part with most of its men.

Major R. H. Davies of Chicago, who is assistant adjutant of the sanitary train and acting director of field hospitals, is living in hopes that the contingents from the northern camps who are to be brought here will be of such excellence as to more than balance the loss of men and training time entailed by this transfer.

November 1 has been officially set as the date for the beginning of a comprehensive course of training for the enlisted and commissioned personnel of the medical department in this division. Major R. H. Davies is to have general supervision of the training under the direction of Lieut.-Col. Robert M. Thornburg, division surgeon, and his assistant, Major R. R. Jones of Fort Oglethorpe and Pittsburgh. The course in gas defense, which will be very complete, will be given by Captain Gussow, who is attached to the division surgeon's office and sent here from the school for gas defense at Fort Sill, Okla.

Colonel Chamberlin of the Surgeon-General's Office made a sanitary inspection of Camp Pike, Sunday, October 28. It would have been difficult to find anything resembling dirt in the sanitary train area for some hours before his arrival.

A lieutenant-colonel, a line officer, who visited the area a few days ago, said that this section of the camp had made more elaborate and successful effort at beautifying their surroundings than any other part of the camp which he had visited.

It "spoke well" he said for the "spirit" of the medical personnel. One thing is certain, no branch of the service has shown a greater willingness to do their full duty than have the medical profession who have left their "all" and have entered on this strenuous and in a way very unnatural existence.

One is vividly impressed with the difference between an enlisted personnel acquired by choice and one acquired by draft in the comparison of the Red Cross Ambulance Company of Topeka, Kan., now a part of the sanitary train, with the material many of the companies here may have to work with. This company is commanded by Lieutenant Lerrigo of Topeka, a member of the Kansas State Board of Health and an author of note. His four junior officers are all graduates of Washburn College and a large percentage of the 118 members of this company are from the same institution.

These men give a "sing" every Tuesday night in their barracks, which is very largely attended by the officers of the sanitary train.

Last week Liberty Loan Day was observed by the 312th Sanitary Train. The exercises were in charge of Capt. J. B. Steele, M. R. C., of Chattanooga, and an address was delivered by a prominent attorney of Little Rock. Over $10,000 was subscribed by the members of the train.

Health conditions are in general good in the Eighty-Seventh Division. The epidemic of measles seems to be abating somewhat.

Among those who have been notified of their promotion recently are Lieut. R. H. Davies of Illinois and Capt. J. W. Thornton of Iowa to the rank of Major, and Lieuts. J. B. Steele of Tennessee, A. J. Lyons of Illinois, C. A. Richards of Wisconsin and Paul R. Howard of Nebraska to the rank of Captain.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Oct. 26, 1917

1. Total strength of troops 1,000,971
   Admission rate per 1,000 (disease only) ....annual 927.5
   Non-effective rate (all causes) 22.8
2. National Guard-strength 315,717
   Admission rate per 1,000 all camps (disease only)..annual 1,056.8
   Non-effective rate all camps (all causes) 26.1

The following camps show admission rate for disease higher than average: Wheeler, Beauregard, A. L. Mills, Cody, Kearney, Sevier, Doniphan, Shelby and Bowie.

The following camps showing non-effective rate higher then average: Beauregard, A. L. Mills, Wheeler, Shelby, MacArthur and Bowie.

3. National Army—strength 413,717
   Admission rate per 1,000 all camps (disease only)..annual 900.4
   Non-effective rate all camps (all causes) 18.7

The following camps show admission rate for disease higher than average: Pike, Dix, Travis, Jackson, Lewis and Dodge.

The following camps show noneffective rate, all causes, higher than average: Pike, Lewis, Dix, Dodge and Travis.

4. Venereal Diseases:

Admission rate regulars	63
Admission rate National Guard (camps)	[illegible]
Admission rate National Army	[illegible]

The following camps, National Guard, have rate above average: Wheeler, Sheridan, Sevier, A. L. Mills, Logan and Bowie.

The following camps, National Army, have rate above average: Pike, Jackson, Dix, Lee, Travis, Lewis and Gordon.

5. Number of cases of pneumonia	[illegible]
Highest number in any one camp	Taylor [illegible]
Number of cases of meningitis	[illegible]
Highest number in any one camp	Dodge 4

ORDERS TO OFFICERS OF THE MEDICAL CORPS

Major **EDWARD W. LAZELL**, Colorado N. G., specialist in nervous and mental diseases, to be relieved from duty with Field Hospital Company No. 4, Camp Mills, Garden City, L. I., N. Y., and to report in person *to the commanding general of the camp hospital* and to the commanding officer of Base Hospital No. 36, *United States Army General Hospital No. 1, New York, N. Y.*, for duty in his specialty.

Lieut.-Col. **GEORGE N. CRABTREE**, U. S. Army, retired, now on duty as assistant chief surgeon, Aviation Section, Signal Corps, U. S. Army, Washington, D. C., in addition to his present duties to be assigned to temporary duty as *Attending Surgeon, Washington, D. C.*, during the absence of Lieut.-Col. Theodore C. Lyster, Medical Corps.

Major **WILLIAM K. BARTLETT**, now at Walter Reed General Hospital, Takoma Park, D. C., to be relieved from station at Fort Des Moines, Iowa, and directed to report in person *to the commanding officer at Walter Reed General Hospital, Takoma Park, D. C.*

Major **CHARLES E. DOERR** upon the arrival of Major Osgood at Fort Ontario, N. Y., to be relieved from duty with Field Hospital No. [illegible], Fort Ontario, N. Y., and directed to proceed *to Fort Ethan Allen, Vt.*

Major **BENJAMIN B. WARRINER**, now on duty in connection with aviation, to be assigned *to duty with the Aviation Section, Signal Corps at S. C. Aviation School, Mineola, L. I.*

Lieut. **NICHOLSON F. CURTIS**, now on duty in connection with aviation, to be assigned *to duty with the Aviation Section, Signal Corps, at S. C. Aviation School, Mineola, L. I.*

Major **JOHN T. AYDELOTTE** to be relieved from duty at Fort D. A. Russell, Wyoming, and directed to proceed *to Fort Sam Houston, Texas.*

Lieut. **JAMES I. GLOAT** to be relieved from duty at Fort Bliss, Texas, and directed to proceed *to New York, N. Y., Port of Embarkation.*

Major **EDGAR D. CRAFT**, U. S. Army, retired, to be relieved from duty at Camp Dodge, Des Moines, Iowa, on arrival of Major Alexander T. Cooper, Medical Corps, and directed *to report by wire to the commanding general, Western Department, for assignment to duty.*

Major **SIDNEY L. CHAPPELL**, now on duty at Fort Benjamin Harrison, Ind., to be directed to proceed *to Madison Barracks, N. Y.*

Lieut. **GERALD C. BATES**, N. G., Adrian, Mo., to be ordered to active duty and directed to proceed to Fort Sill, Oklahoma, and report in person *to the commanding general, Camp Doniphan*, that place, for duty.

Major **JOHN P. FLETCHER**, now on duty at the Motor Ambulance Depot, Louisville, Ky., *to proceed to Washington, D. C.*, and report in person to the Surgeon-General of the Army for consultation.

Major **CHARLES T. KING** to be relieved from duty with the 57th Infantry, Fort Sam Houston, Texas, and directed to proceed *to Camp Mills, Garden City, L. I., N. Y.*, for duty as commanding officer of the base hospital.

Lieut. **LLOYD E. TEFFT** to be relieved from duty at Fort Grant, Canal Zone, and directed to proceed *to Camp Mills, Garden City, L. I., N. Y.*

Capt. **HARRY J. O'BRYAN**, N. G., Watertown, S. D., *to proceed to Fort Snelling, Minn.*

Major **WILLIAM B. BORDEN** to be relieved from duty at Madison Barracks, N. Y., and directed to proceed *to Fort Benjamin Harrison* for the purpose of organizing and commanding Hospital Train 20.

Major **JOHN W. MEEHAN** to be relieved from duty at Syracuse, N. Y., and directed to proceed *to Fort Benjamin Harrison*, to organize and command Hospital Train 21.

To report before the president of the board appointed in Paragraph 19, Special Orders, No. 50, War Department, March 2, 1917, *for examination for promotion*, Col. **HENRY D. SNYDER**, office of the Surgeon-General of the Army, Washington, D. C.; Majors **WILLIAM K. BARTLETT**, Walter Reed General Hospital, Takoma Park, D. C.; **WILLIAM A. DUNCAN**, office of the Surgeon-General of the Army, Washington, D. C.; and **PAUL L. FREEMAN**, Fort Meyer, Va.

Major **HERBERT C. GIBNER**, now on duty in the Hawaiian Department, to be directed to report to the president of the board to be convened by the commanding general, Hawaiian Department, for examination for promotion.

Col. **ALBERT E. TRUBY**, now on duty in the Panama Canal Department, to report in person to the president of the board to be convened by the commanding general, Panama Canal Department, for examination for promotion.

To report to the president of the board to be convened by the commanding general, American Expeditionary Force, France, for examination for promotion, Col. **JAMES R. CHURCH**; Lieut.-Cols. **CHARLES L. FOSTER**, **JAMES D. HEYSINGER** and **JOSEPH F. SILER**; Majors **THOMAS W. BURNETT**, **ROBERT M. CULLER**, **LUCIUS L. HOPWOOD**, **CLEMENS W. McMILLIAN**, **HENRY J. NICHOLS**, **OMAR W. PINKSTON**, **GUY V. RUKKO**, **ARTHUR N. TASKER** and **HARRY H. VAN KIRK**.

To report to the president of the board to be convened by the commanding general, Western Department, for examination for promotion, Col. **ELMER A. DEAN**, Presidio, San Francisco, Calif.; Lieut.-Col. **WILLIAM H. TEFFT**, Fort Douglas, Utah; and Major **WILLIAM R. DAVIS**, Fort Rosecrans, Calif.

To report to the president of the board to be convened by the commanding general, Central Department, for examination for promotion, Cols. **PERCY M. ASHBURN**, Fort Benjamin Harrison, Ind.; and **HENRY S. GREENLEAF**, Fort Snelling, Minn.; Lieut.-Cols. **HENRY F. PIPES** and **GIDEON McD. VAN POOLE**, Fort Benjamin Harrison, Ind.; Majors **HENRY C. PILLSBURG**, Fort Riley, Kan.;

WILLIAM S. SHIELDS, Chicago, Ill.; FRANK W. WEED, Camp Funston, Fort Riley, Kan.; HOWARD H. BAILY, Camp Grant, Rockford, Ill.; and WILLIAM A. WICKLINE, St. Louis, Mo.

To report to the president of the board to be convened by the commanding general, Eastern Department, for examination for promotion, Col. FRANCIS M. C. USHER, Fort Slocum, N. Y.; Lieut.-Cols. ORVILLE G. BROWN, Camp Mills, Garden City, L. I., N. Y.; JOHN R. BOSLEY, Fort Ontario, N. Y.; SAMUEL M. DeLOFFRE, Plattsburg Barracks, N. Y.; GEORGE F. JUENEMANN, Reorganization Camp, Gettysburg, Pa.; HENRY D. THOMASON, Fort Ontario, N. Y.; Majors WILLIAM C. DAVIS, Camp Dix, Wrightstown, N. J.; CHARLES L. GANDY, Allentown, Pa.; PAUL W. GIBSON, New York City; LOUIS H. HANSON, Syracuse, N. Y.; HARRY G. HUMPHREYS, Fort Hancock, N. J.; EDGAR C. JONES, Newport News, Va.; FREDERICK E. MACY, Fort Jay, N. Y.; FERDINAND SCHMITTER, Camp Lee, Petersburg, Va.; and WILLIAM W. VAUGHAN, Allentown, Pa.

To report to the president of the board to be convened by the commanding general, Southern Department, for examination for promotion, Lieut.-Cols. WILLIAM P. BANTA, Nogales, Ariz.; ROBERT L. CARSWELL, Fort Sam Houston, Tex.; and ROBERT C. LOVING, San Antonio, Tex.; Majors CLARENCE L. COLE, Fort Sam Houston, Tex.; and EIDE F. THODE, Fort Clark, Tex.

To report to the president of the board to be convened by the commanding general, Southeastern Department, for examination for promotion, Lieut.-Cols. CRAIG R. SNYDER, Camp McClellan, Anniston, Ala.; ARTHUR M. WHALEY, Camp Sevier, Greenville, S. C.; and LOUIS C. DUNCAN, Fort McPherson, Ga.; Majors CHARLES E. FREEMAN, Camp Pike, Little Rock, Ark.; CHARLES W. HAVERKAMPF, Fort Oglethorpe, Ga.; LEARTUS J. OWEN, Camp Greenleaf, Fort Oglethorpe, Ga.; and EDWARDS C. REGISTER, Hot Springs, Ark.

Major GLENN I. JONES, now on duty at Camp Devens, Ayer, Mass., Northeastern Department, to report to the president of the board to be convened by the commanding general, Northeastern Department, for examination for promotion.

Lieut.-Col. JUNIUS C. GREGORY to be relieved from duty at the Medical Officers' Training Camp, Fort Benjamin Harrison, Ind., and directed to proceed *to Fort Oglethorpe, Ga.,* for duty as instructor.

Major LEARTUS J. OWEN to be relieved from duty at the Medical Officers' Training Camp, Camp Greenleaf, Fort Oglethorpe, Ga., and directed *to proceed to Washington, D. C.,* and report in person to the Surgeon-General of the Army, for duty in his office.

Col. ALEXANDER N. STARK, now on duty at headquarters, Southeastern Department, Charleston, S. C., as department surgeon, to be directed *to proceed to Washington, D. C.,* and report in person to the Surgeon-General of the Army for consultation.

Col. HENRY C. FISHER, now at Camp McClellan, Anniston, Ala., *to proceed to Vicksburg, Miss.,* for the purpose of investigating and reporting on the suitability, for medical purposes, of the camp of Confederate Veterans at that place.

Capt. THOMAS J. LYNCH, N. G., to be relieved from duty with Field Hospital No. 137, Sanitary Train No. 110, Camp Doniphan, Fort Sill, Oklahoma, and *to report in person to the commanding officer of the base hospital, Fort Sill, Oklahoma,* for duty.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Boston, Mass., for a course of instruction in orthopedic surgery from the Army Medical School, Lieut. HENRY W. GRADY, Birmingham.

To Camp Beauregard, Alexandria, La., for duty, Lieuts. JOHN M. BALL, Eufaula; CLIFFORD V. MAYHALL, Naleyville.

To Camp Jackson, Columbia, S. C., for duty from Fort O., Columbia, S. C., for duty, from Fort O., Lieuts. ROBERT GOLDWAITE, Montgomery; OTIS W. LITTLE, Salco.

To Camp Mills, Garden City, L. I., 41st Division, for duty, from Camp Greenleaf, Lieut. WILLIAM C. HATCHETT, Toney.

To Camp Sevier, Greenville, S. C., for duty, Lieut. COLUMBUS M. WOOLEY, Thorsby.

To Camp Shelby, Hattiesburg, Miss., from Camp Greenleaf, for duty, Lieut. ALBERT D. McFADDEN, Bellwood.

To Camp Wheeler, Macon, Ga., for duty, Lieut. LEWIS H. HAMNER, Camp Hill.

To Camp Wheeler, Macon, Ga., for duty, Lieutenant CRENSHAW, Hope Hill.

To Fort Benjamin Harrison, for duty in connection with orthopedic work, Lieut. WYATT S. ROBERTS, LaFayette.

To Fort Oglethorpe, Ga., for a course of instruction, Lieut. ALEXANDER W. GRAVES, Ashland.

To Fort Oglethorpe, Ga., for a course of instruction, Lieut. RAYFORD HODGES, Woodville.

To Neurological School, Chicago, Ill., for intensive training in brain surgery, from Fort O., Lieut. W. THEO. LANGLEY, Camp Hill.

To Philadelphia, Pa., University Hospital, for a course of instruction in fracture and upon completion of this course to proceed to Montgomery, Ala., for temporary duty as surgical assistant, from Fort O., Capt. WILLIAM M. JORDAN, Birmingham.

To his home and the inactive list of the Medical Reserve Corps from Camp Sheridan, Capt. CHARLES A. THIGPEN, Montgomery.

Arizona

To Camp Cody, Deming, N. M., for duty, Lieut. ROBER V. PARLETT, White River.

Arkansas

To Camp Beauregard, Alexandria, La., for duty, from Fort Riley, Lieut. PHILIP H. THOMAS, Jr., Clarendon.

To Camp Dodge, Des Moines, Ia., and report to the Commanding Officer for duty in the genito-urinary and dermatologic section, Lieut. VELPESA H. RAGSDALE, Fitzhugh.

To Camp Doniphan, Fort Sill, Okla., for duty from Fort Riley, Lieuts. MATT F. HOUSTON, Clarendon; for duty in the division of ophthalmology, section of surgery of the head, ARIS. W. COX, Helena.

To Camp Greenleaf, Fort O., for a course of instruction, Lieut. MARSHALL ALLEN, O'Kean.

To Camp Jackson, Columbia, S. C., for duty from Fort Oglethorpe, Lieut. DEWELL GANN, Jr., Little Rock.

To Camp Logan, Houston, Tex., for duty, from Fort Riley, Lieut. PAT MURPHY, Little Rock.

To Camp MacArthur, Waco, Tex., for duty, Capt. ANTHONY C. THIELLIERS, Varner.

To Fort Benjamin Harrison, for a special course of instruction in tuberculosis examination, Capt. PERRY C. WILLIAMS, Texarkana.

To Fort Oglethorpe, Ga., for a course of instruction, Lieut. LOREN WALLIN, Dermett.

To Fort Oglethorpe, Ga., for a course of instruction, Lieut. ERTON E. POYNER, Green Forest.

To St. Louis, School of Plastic and Oral Surgery, Washington University, for a three weeks' course of intensive training in head surgery, from Fort Oglethorpe, Lieut. JAMES W. BUTTS, Helena.

California

To Camp Cody, Deming, N. M., for duty, Lieut. LIVA C. McLAIN, Bakersfield.

To Camp Jackson, Columbia, S. C., for duty from Fort Oglethorpe, Lieut. ARTHUR M. GREENWOOD, San Diego.

To Camp Lewis, American Lake, Washington, for duty in the laboratory of the base hospital, Lieut. ROY W. HAMMACK, Los Angeles.

To Camp Mills, Garden City, L. I., 41st Division for duty, from Allentown, Pa., Lieut. FRANK E. McCULLOUGH, Lincoln.

To Camp Mills, Garden City, L. I., 41st Division, for duty, from Fort Benjamin Harrison, Ind., Lieut. SMITH S. JOHNSON, San Francisco.

To Houston, Texas, Aviation Section, Signal Corps, for duty, Capt. LOREZO F. LUCKIE, Los Angeles.

To Los Angeles, Calif., Aviation Section, Signal Corps, for duty, Capt. WILLIAM H. ROBERTS, Sonora.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieut. BRUNO F. SANDOW, Oakland.

To New York, N. Y., for instruction in orthopedic work, from the Army Medical School, Washington, Lieut. ORAL B. BOLIBAUGH, Reedley.

To Post Graduate Hospital, New York City, for a course of instruction in urology, from U. S. Army Transport *Sherman,* San Francisco, Lieut. THOMAS R. PETCH, Eureka.

To Report to Commanding Officer, Western Department, for duty, Lieut. JOSEPH H. GATTON, San Francisco.

To San Francisco, Calif., Aviation Section, Signal Corps, for duty, Lieut. ELBRIDGE J. BEST, San Francisco.

To San Francisco, University of California, for duty, Lieut. FREDERICK C. LEWITT, San Francisco.

Honorably discharged from the Medical Reserve Corps on account of being physically disqualified for active service, Lieut. JOHN C. PAINE, Exeter.

Canal Zone

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Captain EDWARD P. BEVERLEY, Balboa.

To New York, N. Y., for instruction in orthopedic work, from Army Medical School, Washington, D. C., Panama City.

To Washington, D. C., and report to the surgeon-general for instructions, Capt. HERBERT C. CLARK, Ancon.

Colorado

To Boston, Massachusetts General Hospital, from Medical Officers' Training Camp, Fort Riley, Kan., for a course of instruction on fractures and on completion of this duty to Camp Doniphan, Fort Sill, Okla., for temporary duty as surgical assistant, Capt. CLARENCE B. INGRAHAM, Jr., Denver.

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, Lieut. DANIEL B. RILEY, Ignacio.

To Camp Logan, Houston, Tex., for duty from Fort Riley, Lieuts. WINFIELD S. CLELAND, Delta; BERT MENSER, Denver.

To Camp Travis, Fort Sam Houston, Texas, for duty, from Fort Riley, Kan., Lieut. ALECK F. HUTCHINSON, Durango.

To Fort Benjamin Harrison, Hospital Train 20, for duty, from Medical Officers' Training Camp, Fort Benjamin Harrison, Lieut. WILLIAM C. LUCAS, Weldona.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieuts. WILLIAM W. JONES, Denver; Lieut. ROBERT LEVY, Denver.

To New York City, Bellevue Hospital, for a course of instruction in fractures and on completion of this duty to Camp Custer, Battle Creek, Mich., 85th Division, for temporary duty, from Camp Custer, Lieut. ROBERT G. PACKARD, Denver.

To St. Louis, School of Plastic and Oral Surgery, Washington University, for a three weeks' course of intensive training in head surgery, from Fort Riley, Lieut. FRED H. CARPENTER, Denver.

Connecticut

To Boston, Mass., for a course of instruction in orthopedic surgery from the Army Medical School, Lieut. FREDERICK K. HERPEL, Hartford.

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, Capt. ROBERT E. PERDUE, Norwich.

To Camp McClellan, Anniston, Ala., for duty as assistant to the chief of the Medical Service, from Fort Benjamin Harrison, Lieut. JOHN C. ROWLEY, Hartford.

To Fort Oglethorpe, Ga., for a course of instruction, Lieuts. LeVERNE HOLMES, Manchester; RUSSELL B. STREET, Suffield.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Capt. MICHAEL J. SHEAHAN, Derby.

To New Haven, Conn., Aviation Section, Signal Corps, for duty, Capt. HAROLD S. ARNOLD, New Haven.

To Rockford, Ill., for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, Lieut. CHARLES H. TURKINGTON, Pitchfield.

Delaware

To Camp Meade, Annapolis Junction, Md., for duty, Lieut. ROBERT R. ROTH, New Castle.

To St. Louis, School of Plastic and Oral Surgery, Washington University, for a three weeks' course of intensive training in head surgery, from Fort Riley, Lieut. JOHN B. ELLIOT, Laurel.

District of Columbia

To Boston, Mass., for a course of instruction in orthopedic surgery, from the Army Medical School, Lieuts. JOHN R. DeVELLING, Washington; EDWARD B. MACON, Washington.

To Camp Wheeler, Macon Ga., for duty, from Fort Oglethorpe, Capt. FRANCIS P. MORGAN, Washington.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieut. CHARLES W. HYDE, Washington.

To Neurological School, Chicago, Ill., for a course of instruction in brain surgery, Lieut. GRAFTON D. TOWNSHEND, Washington.

To New York, N. Y., for instruction in orthopedic work, Capt. EARL OSTERHAUS, Washington.

To the Office of the Surgeon-General, for duty in charge of the subdivision of otolaryngology, section of surgery of the head, Major CHARLES W. RICHARDSON, Washington.

Honorably discharged from the Medical Reserve Corps, Capt. VICTOR B. RENCH, Washington.

Florida

To Boston, Mass., for a course of instruction in orthopedic surgery, from the Army Medical School, Lieut. LAURENT L. LAROCHE, Cocoa.

To Camp Jackson, Columbia, S. C., for duty from Fort Oglethorpe, Lieut. LOUIS B. BOUCHELLE, Sanford.

To Camp Lee, Petersburg, Va., for duty, to be relieved from his present duties at that camp, Lieut. BENNETT A. BURKE, Titusville.

To Camp Mills, Garden City, L. I., 41st Division, for duty, from Allentown, Lieuts. PAUL L. GOSS, Mulberry; WILLIE J. VINSON, Tarpon Springs.

To Fort Oglethorpe, for a course of instruction, Lieut. THOMA E. PARRISH, Dania.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieuts. JAMES L. PENNINGTON, Fountain; CLAUDE V. GAUTIER, Passagrille.

To his home and the inactive list of the Medical Reserve Corps on account of being physically disqualified for active service, from Allentown, Pa., Lieut. EDGAR S. STRICKLAND, Miccosukee.

Georgia

Honorably discharged from the Medical Reserve Corps, Lieut. FRANCIS A. McMULLIN, Philadelphia.

Rhode Island

To Boston, for duty in connection with the division of otolaryngology, section of surgery of the head, Capt. ALVAH A. FISHER, Providence.

To Rockford, Ill., for duty from Fort Riley, Lieut. BYRON J. BROWN, Providence.

South Carolina

To Camp Jackson, Columbus, S. C., for duty, from Fort Oglethorpe, Lieuts. JAMES A. NORTON, Conway; FRANK D. MOWER, Newberry.

To Camp Wadsworth, Spartanburg, S. C., for duty, Lieut. BENTON McQ. MONTGOMERY, Kingstree.

To Fort Oglethorpe, for a course of instruction, Lieuts. DANIEL D. STRAUSS, Bennettsville; *DAVID L. BRYSON,* Winnsboro.

To Philadelphia, for temporary duty in the Aviation Section, Signal Corps, and on completion to return to Charleston, S. C., for duty in the *physical* examining unit, *Aviation Section, Signal Corps, Capt.* CHARLES W. KOLLOCK, Charleston.

South Dakota

To Camp Beauregard, Alexandria, La., for duty, from Fort Riley, Lieut. FRED F. KEENE, *Wessington Springs.*

To Camp Dodge, Des Moines, Iowa, for temporary duty, Capt. ALBERT E. BROWN, *Webster.*

Tennessee

To Army Medical School, Washington, D. C., *for the required course of* instruction, Lieut. STEWART LAWWILL, Chattanooga.

To Camp Beauregard, Alexandria, La., for duty, Lieut. JOHN W. FROST, *Dyer.*

To Camp Jackson, Columbia, S. C., for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, Lieuts. LEOPOLD SHUMACKER, Chattanooga; OWEN S. DEATHERIDGE, Nashville; for duty, from Fort Oglethorpe, Lieut. JUSTIN E. LACY, Jasper.

To Camp Sevier, Greenville, S. C., from Fort Oglethorpe, for duty, Lieuts. GEORGE E. WILSON, Cardiff; HERBERT ACUFF, Knoxville: KYLE C. COPENHAVER, Mascot; WILLIAM H. DELOP, *LaFollette.*

To Fort Oglethorpe, for a course of instruction, Lieuts. WILLIAM K. VANCE, Jr., Bristol; WENDALL P. BAUGH, Elkton; THOMAS W. MENSEE, Nashville; WILLIAM A. CASHION, Puryear.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieut. CLYDE C. HARDISON, Lewisburg.

To New Orleans Charity Hospital, for a course of instruction on fractures, and on completion of this course to proceed to Hattiesburg, Miss., for temporary duty as surgical assistant, from Fort Oglethorpe, Lieut. DANIEL B. CLIFFE, Franklin.

To St. Louis School of Plastic and Oral Surgery, Washington University, *for a three weeks' course of intensive training in head surgery,* from Fort Oglethorpe, Lieut. DORSEY T. GOULD, Lawrenceburg.

Texas

To Army Medical School, Washington, D. C., for the required course of instruction, Lieut. WILLIAM E. NESBIT, *San Antonio.*

To Boston, for a course of instruction in orthopedic surgery, *from* the Army Medical School, Lieuts. EDMUND D. MILLS, *Galveston;* ROBERT L. HOWELL, *Snyder.*

To Camp Bowie, Fort Worth, Texas, for duty, Lieut. ROBERT B. WOLFORD, Childress.

To Camp Cody, Deming, N. M., for duty, Lieuts. HENRY BRADBROOK, Cat Springs; ROBINSON H. SALMON, Maypearl; JOSEPH V. DOZIER, Menard; ISADOR BRAUN, Shiner.

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, Lieut. JESSE LEE HALL, Bertram.

To Camp Logan, Houston, Texas, for duty from Fort Riley, Capt. ALE OLSON, Morse.

To Camp MacArthur, Waco, Texas, for duty, Lieuts. JOHN W. BROWN, Pearsall; WESLEY S. NEAL, Weatherford.

To Camp Travis, Fort Sam Houston, Texas, for duty as a member of a board of medical officers for the special examination of the command for tuberculosis, Capt. GEORGE S. MILNEA, Houston; for duty as plastic and oral surgeon, section of surgery of the head, from School of Plastic and Oral Surgery, Washington University, St. Louis, Capt. ROBERT F. MILLER, Brenham.

To Fort Oglethorpe, for a course of instruction, Lieuts. ERNEST J. STEVES, San Antonio; C. ZENO HOLT, Texaline.

To Love Field, Hawes, Texas, for duty with the Signal Corps, Aviation School, Lieut. JAMES T. COLWICK, Dallas.

To Mineola, L. I., Aviation Section, Signal Corps, for duty, Lieuts. CLIFFORD C. PARRISH, Fort Worth; OMER O. GAIN, Honey Grove; GARNETT MILLER, Moody; AARON L. ROBERTS, Myra; ARTHUR G. NEIGHBOR, Rosenberg; HENRY W. PICKETT, Sulphur Springs.

To New Orleans Charity Hospital, for a course of instruction in fractures and on completion of this duty to Camp Logan, Houston, Texas, Thirty-Third Division, for temporary duty in the base hospital, from base hospital, Camp Logan, Houston, Texas, Lieut. WILLIAM P. BARTON, Overton.

To report by telegraph to the commanding general, Southern Department, for assignment to duty, from Camp Cody, Deming, N. M., Capt. JOSEPH S. JONES, Galveston.

To report by wire to the commanding general, Southern Department, for assignment to duty, Lieuts. MARCUS M. CARR, GEORGE B. MILLER, Dallas.

Utah

To Fort Oglethorpe, for the required course of instruction, from Camp Beauregard, Alexandria, La., Lieut. FRANCIS C. TYNG, Salt Lake City.

Vermont

To Boston City Hospital, from Fort Ethan Allen, Vt., for a course of instruction in fractures and on completion of this course to proceed to Fort Ethan Allen, Vt., and report to the commanding general, Northeastern Department, Lieut. ROBERT L. MAYNARD, Burlington.

Virginia

To Boston, for a course of instruction in orthopedic surgery, from the Army Medical School, Lieut. PERCY E. DUGGINS, Norfolk.

To Camp Greenleaf, Fort Oglethorpe, for a course of instruction, Lieut. FRANK L. WYSOR, Clifton Forge.

To Mineola, L. I., N. Y., Aviation Concentration Camp, for duty, from Essington, Pa., Capt. JOSEPH N. BARNEY, Fredericksburg; Lieut. HARRY D. HOWE, Hampton.

To Philadelphia, School of Plastic and Oral Surgery, Evans Dental Institute, for a three weeks' course of intensive training, Lieut. SAMUEL P. CAST, Portsmouth.

To return to the inactive list of the Medical Reserve Corps, Lieut. HARRY D. HOWE, Hampton.

Washington

To Chicago Neurological School, for a course of instruction in brain surgery, Lieut. GEORGE W. SWIFT, Seattle.

To communicate by telegraph with the commanding officer, Western Department, for assignment to duty, Capt. ALBERT LESSING, Seattle.

To communicate by telegraph to the commanding general, Western Department, for assignment to duty, Capt. MARION M. NULL, Seattle.

To Fort Oglethorpe, Ga., for a course of instruction, Lieut ARTHUR B. GOULD, Kent.

West Virginia

To Camp Meade, Annapolis Junction, Md., for duty, Lieut. MICHAEL P. LINK, *Matewan.*

To Camp Greenleaf, Fort Oglethorpe, Ga., for a course of instruction, Lieut. *JULIUS C. SCHULTZ,* Huntington.

To Camp Lee, Petersburg, Va., for duty, Lieuts. HARLOW R. CONNELL, Kimball; JOHN S. GIBSON, Wevaco.

To Camp MacArthur, Waco, Texas, for duty, from Fort Benjamin Harrison, Lieut. GEORGE W. SHRIVER, Clendenin.

To Fort Oglethorpe, for a course of instruction, Lieut. RUFUS E. WOODALL, Charleston.

Honorably discharged from the Medical Reserve Corps, on account of being physically disqualified for active service, Lieut. JAMES R. *VERMILLION,* Princeton.

Wisconsin

To Boston, Massachusetts General Hospital, from Medical Officers' Training Camp, Fort Riley, for a course of instruction on fractures and on *completion of this duty to Camp Pike, Little Rock, Ark.,* for temporary duty as surgical assistant, Lieut. FRANK H. RUSSELL, Neenah.

To Camp Beauregard, Alexandria, La., for duty, Lieut. JOHN E. McGINNIS, Green Bay.

To Camp Custer, Battle Creek, Mich., for duty, Capt. CLEMENT F. DOUGHERTY, Richland Center.

To Camp Doniphan, Fort Sill, Okla., for duty from Fort Riley, Kan., Lieut. HARRY E. MacLAUGHLIN, Waupaca.

To Camp Grant, Rockford, Ill., for duty, Lieut. WILLIAM T. LOCHEMES, Milwaukee.

To Camp Logan, Houston, Texas, for duty from Fort Riley, Lieuts. WILLIAM H. *REMER, Chaseburg; LESLIE J. PHILLIPS,* Weyerhauser.

To Camp Travis, Fort Sam Houston, Texas, for duty, *from Fort* Riley, Kan., Lieut. ERNEST C. HOWELL, Fennimore; RALPH T. GILCHRIST, Milwaukee; JOHN H. HOGAN, Racine.

To Fairfield, Ohio, Signal Corps, Aviation Section, for duty with the squadron at that station, Capt. WILL G. MERRILL, Grand Rapids.

To Fort Oglethorpe, for a course of instruction, Lieuts. JAMES G. CONLEY, Darlington; LEON H. FLANCHER, Milwaukee.

To Kelly Field, Signal Corps, Aviation School, San Antonio, Texas, from Fort Benjamin Harrison, Lieut. JAMES J. FITZGERALD, Eagle.

To Los Angeles, for a course of *instruction* in military roentgenology, Lieut. JAMES P. GILLIS, Deerbrook.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

New Officers Elected.—At a meeting of the California Board of Medical Examiners, held October 15, the following officers were elected: Dr. Percy T. Phillips, Santa Cruz, president; Dr. Harry V. Brown, Los Angeles, vice president, and Dr. Charles B. Pinkham, San Francisco, secretary-treasurer.

New Tuberculosis Sanatorium.—The board of supervisors of Los Angeles County has recommended the purchase of the 454-acre Wilson ranch property at Sylmar, in the San Fernando Valley, as a site for a tuberculosis sanatorium for the joint use of Los Angeles, Santa Barbara and Ventura counties. It is planned to expend $100,000 for the erection of buildings, of which Los Angeles will appropriate $70,000, the balance being divided between Santa Barbara and Ventura counties.

DISTRICT OF COLUMBIA

Physicians Plan Club.—The District Medical Society is planning to erect a club house to cost $100,000. The building will have an amphitheater with a seating capacity of 600.

Society Celebrates Centennial.—October 17, the Medical Society of the District of Columbia celebrated its one hundredth anniversary. The meeting was held at the New National Museum, and was presided over by Dr. G. Wythe Cook, who made an address formally instituting the celebration of the society centennial. Addresses were then made by Dr. Guy Steele, Cambridge, president of the Medical and Chirurgical Society of Maryland; Dr. John Champlin, president of the Rhode Island Medical Society, and Dr. Elmer B. Cooley, Danville, president of the Illinois State Medical Society. A historical address was delivered by Dr. Daniel Smith Lamb. At the centennial banquet held at the Hotel Raleigh in the evening, Dr. Joseph Stiles Wahl officiated as toastmaster.

GEORGIA

Tuberculosis Clinics.—At the trimonthly meeting of the Central Council of Charitable and Philanthropic Organizations of Savannah, held October 9, recommendations were made for the establishment of three tuberculosis clinics.

License Revoked.—A report from the State Board of Medical Examiners of Georgia states that the license of Dr. Charles W. Miller, Atlanta, has been revoked on the ground that he had sold forged eclectic licenses to two individuals to practice medicine.

First District Physicians Elect Officers.—At the annual meeting of the Congressional District Medical Society, held in Savannah, Statesboro was selected as the next place of meeting, and the following officers were elected: president, Dr. Robert L. Miller, Waynesboro, and vice presidents, Drs. Luther A. De Loach, Glennville, and Antonio J. Waring, Savannah.

New State Board Members and Officers.—Dr. Alexander G. Little, Valdosta, has been appointed by the governor as a member of the State Board of Medical Examiners of Georgia, in place of Dr. Frederick D. Patterson, Cuthbert, term expired. Dr. Henry W. Terrell, La Grange, was appointed to fill the vacancy caused by the death of Dr. Francis M. Ridley. At the October meeting of the board, Dr. Jarrett W. Palmer, Ailey, was elected president; Dr. Alfred F. White, Flovilla, vice president, and Dr. Charles T. Nolan, Marietta, secretary-treasurer.

ILLINOIS

Billings and His Russian Experiences.—Dr. Frank Billings, head of the American Red Cross Mission to Russia, will narrate his experiences at the benefit meeting for Russian War Relief, to be held in Orchestra Hall, Chicago, November 13, by the Chicago Anti-Cruelty Society.

Red Cross Council Named.—Dr. George T. Palmer, Springfield, president of the Illinois Tuberculosis Association, has appointed the following as war council to have charge of the sale of 1917 Red Cross seals in the state: Dr. Frank Billings, Chicago; Dr. C. St. Clair Drake, director of the Illinois Department of Public Health; Dr. James W. Pettit, Ottawa, and Mr. W. T. Thurber, association director of the Red Cross for Illinois.

Personal.—Dr. Arrie Bamberger, Chicago, has been appointed attending physician at Cook County Hospital.——Lieut. Walter D. Stevenson, M. R. C., U. S. Army, Quincy, has been ordered to active duty at Camp Sherman, Chillicothe, Ohio, and has been placed in charge of the division of surgery of the head.——Dr. Jonathan M. Wyland, Moline, underwent an operation on the spine, at Mercy Hospital, Davenport, November 2.

Merger of Societies.—It is suggested that ex-interns of the Illinois Charitable Eye and Ear Infirmary, Chicago, who have been gathering about once a year for clinics and discussions, join with graduate interns of other recognized hospitals for the care of the diseases of the eye, ear, nose and throat, that a larger organization may be formed and greater good accrue to the membership. For particulars regarding this new organization, ex-interns are requested to address Dr. Ralph H. Woods, La Salle.

Chicago

Physicians' Club Gives Banquet to Billings.—At a testimonial banquet given to Dr. Billings by the Physicians' Club of Chicago, November 1, a special event was the presentation to Dr. Billings of a silver loving cup with the following inscription:

> "To our friend, Dr. Frank Billings, the great scientist, philanthropist, and patriot. Presented by the Physicians' Club of Chicago, Nov. 1, 1917."

The cup was presented to Dr. Billings, on behalf of the club, by Governor Frank O. Lowden of Illinois, who was introduced by Dr. A. M. Corwin, president of the club. Governor Lowden said in part:

> "The very pleasant duty falls to me tonight to present this handsome loving cup to your distinguished guest of honor. I appreciate more than I can express that this cup has been put in my hands to be placed in his. All of us not only admire Dr. Billings for his great ability during all these years, but personally I have a deep affection for him, and I know that I voice the sentiments of not only those present, but the people of Illinois and of other states when I say that he has justly earned this gift on account of the great and distinguished services he has rendered to humanity, to his country, and as I believe, to the world."

Dr. Arthur O'Neil was next introduced as toastmaster of the evening. Other speakers who addressed the meeting were the Russian Consul, J. Antoine Volkoff, Marquis Eaton of the Chicago chapter of the Red Cross, Dr. Arthur Dean Bevan, President of the American Medical Association, and Dr. William E. Quine.

INDIANA

Conference on Mental Defectives.—The Indiana Society of Mental Hygiene, and the State Committee on Mental Defectives will hold a general conference on mental defects, at the Hotel Claypool, Indianapolis, November 13.

Bonds for Hospital Sold.—A bond issue of $100,000 for the Allen County Tuberculosis Hospital was sold, October 13, to the German-American National Bank of Fort Wayne on a bid of $371 premium. Work on the hospital will be started as soon as the contract is awarded.

Personal.—Dr. Joseph E. Sharp, Indianapolis, was shot and seriously wounded, October 27, by an Italian, who was frenzied with grief on account of the death of his child.——Dr. Oscar E. McWilliams, Anderson, is ill at his home.——Dr. Otto B. Pettijohn was run down by an automobile in Indianapolis, October 22, and was seriously injured about the head and shoulders.—Dr. Solomon P. Stoddard, Indianapolis, was struck and slightly injured by an automobile, October 22.——Dr. Adrian E. Fauve, Fort Wayne, has arrived in Europe.——Dr. Edmund M. Van Buskirk has been appointed president of the Fort Wayne Board of Health, succeeding Dr. Henry O. Bruggeman, resigned to enter the military service.——Dr. Harmer M. Newman, South Milford, is reported to be critically ill.——Dr. Alfred Henry, Indianapolis, has been elected president of the Mississippi Valley Conference on Tuberculosis.

MARYLAND

Training in Hospitals.—The Johns Hopkins Hospital and the South Baltimore Eye, Ear and Throat Hospital have come forward and offered to take some of the men stationed at Fort McHenry and give them practical training. The Hopkins has taken six men, while the South Baltimore Eye, Ear and Throat Hospital has asked for four.

Dinner for Physicians.—A dinner was recently given at the Belvedere Hotel by a number of officers of the Medical

Reserve Corps, selected by the Surgeon-General's Office to take special studies in psychiatry at the Henry Phipps Psychiatric Clinic, in honor of their teachers, Dr. Adolf Meyer, Dr. Charles M. Campbell and Dr. Francis L. Dunham.

Personal.—Dr. Harry S. Jarrett of Towson is a patient at the Mercy Hospital, in Baltimore, where he has been ordered to take absolute rest for several weeks.——Dr. Albert G. Webster, Belmar, has been appointed health officer of the Fourteenth District of Baltimore County, succeeding Dr. William F. Clayton, Overlea, deceased.——Dr. William S. Baer, Baltimore, who went across with the Johns Hopkins unit, has arrived in Paris.

Committee to Study Schoolchildren.—A committee was appointed at a meeting in Baltimore, October 26, to make a survey of all children attending school to determine the number of mentally deficient pupils in Baltimore schools. It will be given a hearing at a meeting of the school board, whose cooperation will be asked in following up the plan. Dr. F. J. Dunham of the Henry Phipps Clinic, Johns Hopkins University, Dr. William T. Howard of the city health board, Dr. Anna D. S. Abercrombie, examining physician of the Bureau of Labor and Statistics, Dr. Arthur P. Herring of the State Lunacy Commission and Mr. J. W. Chapman, Jr., president of the school board, have discussed the question of the best method to adopt to overcome the obstacles that now confront mentally deficient children.

MISSOURI

Social Service Department Opened.—The Barnard Free Skin and Cancer Hospital, St. Louis, has opened up a social service department with two social workers for the investigation of the social side of cancer.

State Board Election.—At a recent meeting of the Missouri State Board of Health, the following officers were elected: president, Dr. Wilson J. Ferguson, Sedalia; vice president, Dr. T. Hurley Wilcoxen, Bowling Green, and secretary, Dr. George H. Jones, Jefferson City. The other members of the board are Dr. Thomas A. Son, Bonne Terre; Dr. Marc R. Hughes, St. Louis; Dr. William A. Clark, Jefferson City, and Dr. Tolman W. Cotton, Van Buren.

Mount St. Rose Sanitarium Rebuilds.—Mount St. Rose Sanitarium, St. Louis, has recently added a new building at a cost of $140,000, the whole plant representing an investment of about $350,000. This institution is devoted exclusively to the care and treatment of tuberculosis, and is the first institution of its kind in the Middle West. It is conducted by the Sisters of St. Mary, and was established by them in 1902. Dr. Louis C. Boisliniere is the medical director.

Personal.—Dr. James E. Ball, Richmond, has been appointed a member of the medical staff of State Hospital No. 2, St. Joseph.——Dr. Elmer T. McGaugh, Richmond, has been appointed physician of Buchanan County, succeeding Dr. James E. Ball.——Dr. John W. Vaughan, St. Louis, was seriously injured in a collision between his automobile and a motor truck, October 24.——Dr. John D. Hayward, St. Louis, is reported to have won the suit brought against him by Mrs. Mary Sparks for $5,000 damages for injuries claimed to have been received by the breaking of an operating table. ——The Surgeon-General of the Army has appointed Major Llewellyn Sale, St. Louis, chief of the medical service for the special study of cardiovascular diseases at Camp Wadsworth, Spartanburg, S. C., and Major Oliver H. Campbell, St. Louis, chief of the medical service of the same study at Camp McArthur, Waco, Texas.——Dr. Porter E. Williams, Bunceton, has been elected superintendent of State Hospital No. 2 at St. Joseph to succeed Dr. Eugene H. Bullock, Edina, appointed land reclamation commissioner.——The death of Dr. James H. Elliott, West Plains, councilor of the Twenty-Seventh District, created a vacancy in that office which the president, Dr. Robert E. Schlueter, has filled by appointing Dr. Henry C. Shuttee, West Plains.——Dr. William A. Clark, Jefferson City, has been appointed penitentiary physician to take the place of Dr. James C. Welch, Salem, resigned.

Conditions of Rural Schools.—Missouri's rural schools show many serious deficiencies in health conditions, according to the report of a sanitary survey of the rural schools of northeast Missouri, which appears in the November issue of the *Rural School Messenger*. The report, which was undertaken by the Department of Chemistry and Sanitation at the State Normal School, especially emphasizes the state's crying need of laws to provide health inspection in the schools. Attention is called to the fact that 98.2 per cent. of the schools investigated have no medical inspection whatever. Only 3.5 per cent. have dental inspection, and only 1.7 per cent. make any effort to examine children for adenoids, although 491 cases were reported to the investigating committee. Provision for testing the eyesight of children is made by only 19.4 per cent., and for testing pupils for defective hearing, by 10.7 per cent. The report cites 311 cases of malnutrition and 646 cases of defects in speech, and although 173 pupils are suffering from spinal curvature and sixty from chorea, scarcely a third of the schools have made any provision for the health and comfort of the defective child. Seating arrangements that are a perpetual invitation to spinal curvature and other physical defects are common, as the great majority of the children are required to sit at desks that cannot be adjusted to their individual needs. Other conditions that militate against the health of the pupils in a large percentage of the schools are lack of disinfection of schoolrooms, polluted water supply, defective toilet arrangements, lack of modern heating and ventilating systems, and improper disposal of sewage. The committee recommends the passage of new health laws, the installation of school physicians, and more liberal support of the various public health agencies of the state.

NEW YORK

Centennial of Medical Society.—At the centennial meeting of the Steuben County Medical Society, held at Bath, October 17, Dr. Francis S. Swain, Corning, was elected president; Dr. Floyd L. Spaulding, Cohocton, vice president, and Dr. D. R. Wakeman, Cornell, secretary-treasurer.

Central Association Meets.—At the forty-ninth annual meeting of the Medical Association of Central New York, held in Auburn, October 18, the following officers were elected: president, Dr. John J. Buettner; vice presidents, Drs. Owen E. Jones, Rochester, and Nelson G. Russell, Buffalo; secretary, Dr. Robert Burns, Syracuse (reelected), and treasurer, Dr. Thomas F. Laurie, Auburn (reelected).

New York City

Harvey Society Lecture.—The second lecture in the Harvey Society series, delivered, November 10, at 8:30, by Dr. Carl L. Alsberg of the United States Department of Agriculture, was on the subject "Current Food Problems."

White Mice Wanted.—As the European war has cut off the supply of white mice, Dr. William H. Park, director of the department of health laboratories, has advertised for all who have white mice for sale to communicate with the research laboratory at the foot of East Sixteenth Street.

Microscopic Society Exhibition.—The exhibition of the New York Microscopic Society was held, November 13, at the National Museum of American History. The exhibition was devoted in a great measure to the demonstration of the department of health of the practical use of the microscope in safeguarding the public health. Demonstrations were also made showing the use of the microscope in the arts, sciences and industries.

Dr. Baruch Honored.—A bronze tablet commemorating Dr. Simon Baruch's connection with the campaign for public baths in this city was unveiled at the Simon Baruch Public Baths, formerly the Rivington Street baths, October 29. The tablet was donated by Mrs. Belle Baruch through the Association for the Promotion of Hygiene and Public Baths. Borough President Marcus M. Marks made the address of acceptance in behalf of the city.

Federal Control of Habit-Forming Drugs.—Police Commissioner Wood has written a letter to the attorney-general strongly urging the United States government to enact additional legislation, placing the sale of the these drugs directly in the hands of the federal government with zone districts for the distribution, and severe penalties for the alteration of certificates calling for drugs. Commissioner Woods states that there are 2,000 arrests of drug users in New York every year.

Is Tuberculosis Adequately Reported?—A recent bulletin of the department of health publishes the statistics pertaining to tuberculosis during the second quarter of 1917, and compares them with the figures for the corresponding period of 1916. The comparison shows a slight decrease in the death rate from pulmonary tuberculosis, and for other forms of the disease as well. There is a very marked decline in the number of new cases reported during the second quarter of 1917. It is pointed out that this would be a source of great satisfaction were there not sufficient evidence to account for the belief that this decrease is accounted for to a certain extent by the failure of many physicians to report cases of tuberculosis under their care to the health [illegible]rtment.

seems that it is still necessary to call the attention of physicians to the sanitary regulation requiring that all cases of tuberculosis be reported to the health department and the failure to do so is a violation of the sanitary code, that is, a misdemeanor which subjects the offender to criminal prosecution.

OREGON

Society Changes Name.—At the meeting of the Klamath County Medical Society, held at Klamath Falls, it was decided to change the name of the organization to the Klamath and Lake County Medical Society.

Personal.—Dr. D. Everette Standard and Susie V. Standard have taken up the practice at Huntington, vacated by the call to military service of Samuel C. Standard.——Dr. William F. Amos, Portland, is ill with otitis media.——Dr. Esther Pohl Lovejoy, Portland, who went to France last August in Red Cross service, is on duty in Paris.——Dr. Edmond J. Labbe, Portland, has started for France.

New Medical Building.—Plans are being made for the construction, at an early date, of the first unit of the new medical school of the University of Oregon. The sum of $117,000 is available for this work. This building and the new county hospital will occupy a site of 20 acres on one of the hills above South Portland. Eventually other buildings are to be erected, comprising all the necessary facilities for a great medical school.

PENNSYLVANIA

State Hospital for Inebriates.—Lewis J. Sadler, Carlisle, was elected president of the commission appointed by the governor to select a site and erect a state hospital for the treatment of inebriates, October 30. The legislature has appropriated $200,000 for this work.

Welfare and Efficiency Conference.—The fifth annual Pennsylvania Welfare and Efficiency Conference will be held in the House of Representatives, Harrisburg, November 21 and 22. These conferences are held annually for the purpose of stimulating discussions on the problems of industries and labor, with special reference to the reduction of the enormous number of diseases and deaths, and the numerous industrial accidents.

Conference of Industrial Physicians and Surgeons.—The Department of Labor and Industry announces that the fifth conference of industrial physicians and surgeons will be held at the state capitol, Harrisburg, November 20. At the morning session the medical and surgical problems of the staff of the largest industries representative of Pennsylvania will be considered, and in the afternoon the question of industrial diseases will be taken up.

War's Levy on the Hospital Interns in Pennsylvania.—Dr. John M. Baldy sends the following data regarding the approved general hospitals in Pennsylvania, and the effect of the war on the interns of these hospitals. According to Dr. Baldy there are seventy-two general hospitals approved for internship in Pennsylvania, and in these there are normally required 418 interns. The total number of interns at present is 327, leaving ninety-one vacancies, or nearly 22 per cent.

Personal.—Dr. Henry W. Linebaugh, New Cumberland, suffered a cerebral hemorrhage, October 22.——Dr. Josiah J. Myers, Nescopeck, fractured several ribs and dislocated a shoulder by a fall at the Berwick Planing Mill.——Dr. John A. McKean, Washington, sustained serious injuries by falling from a ladder, October 18.——Dr. Wallace R. Hunter, Erie, has been reappointed a trustee of the State Hospital for the Insane, Warren.——Dr. Thomas Lambie, for seven years a medical missionary in the Sudan, was appointed a minister of the United Presbyterian Church at a special meeting in Pittsburgh, recently.

Philadelphia

To Conserve Baby Lives.—The Philadelphia Pediatric Society will hold a public meeting, November 13, at the College of Physicians, to devise means for preventing and arousing interest in the infant mortality percentage of the country. Last year 5,200 babies died in Philadelphia before they reached their first birthday.

Moynihan in Philadelphia.—Sir Berkeley Moynihan, senior consulting surgeon of the British Royal Army, who arrived in this country from England a short time ago, was entertained at a dinner at the Bellevue-Stratford Hotel, by the Philadelphia Medical Club, the College of Physicians, the Academy of Surgery and the Philadelphia County Medical Society, November 7.

Infantile Paralysis.—The health department reports that 143 victims of the infantile paralysis epidemic of 1916, under its care, have been cured. This result was accomplished through the combined efforts of the city department with hospitals, dispensaries and private physicians, supplemented by the financial assistance of the Emergency Aid. Of those restored to health, eighty-four patients were treated by private physicians and thirty-eight at dispensaries. Hospitals have discharged four as cured; two other cured were treated in their own homes.

Base Hospital School Will Be Opened Here.—A fully organized school to train the enlisted men of a base hospital has been instituted at the Second Regiment Armory. The new school will be under the direction of Major John S. Lambie, Fort Bliss, Texas, commanding officer, and Major William M. L. Coplin, director of Base Hospital No. 38. The various hospitals of the city have agreed to offer facilities for the training. They will take 153 men, and detail them to duty in wards, dispensaries, operating rooms and laboratories. The men are divided into various units on duty at the Jefferson, Pennsylvania, Samaritan, Jewish, Lankenau, Frankford, Polyclinic and St. Joseph's hospitals. Others are to be detailed to hotels for kitchen work and to familiarize themselves with practical cooking. The first lecture was given, October 27, by Dr. William W. Keen.

TENNESSEE

Memorial Hospital in China.—H. Alexander, Nashville, will erect a hospital at Ping Tu, China, in memory of his wife. The institution will be known as the Luella Roach Alexander Hospital for Women.

New Building Dedicated.—A new building, the Anderson Anatomical Hall, at the Meharry Medical College of Nashville, was dedicated, October 19. It is the gift of Dr. John W. Anderson, Dallas, Texas, who contributed $10,000 for its erection.

Personal.—Dr. Charles S. Briggs has been appointed chief surgeon of the Tennessee Central Railroad, to fill the vacancy caused by the resignation of Dr. Lucius E. Burch, Nashville, who has entered the military service.——Dr. Roy Wells, Clarksville, has been placed in charge of the United Fruit Company's Hospital, Panama.

UTAH

Physicians' Club Organized.—The Physicians and Surgeons Club of Cache Valley was organized at Logan, October 19, with an initial membership of seven. Dr. Heber K. Merrill, Logan, was elected president; Dr. Ralph O. Porter, vice president, and Dr. Ernest P. Oldham, secretary-treasurer, all of Logan.

Health Association Meeting.—At the meeting of the Utah Public Health Association in Salt Lake City, October 4, the following physicians were elected members of the board of directors: Robert W. Ashley, Salt Lake City; Theodore B. Beatty, Salt Lake City; G. H. Brimhall, Provo; Clarence M. Clark, American Fork; R. Garn Clark, Panguitch; Ephraim G. Gowans, Salt Lake City; Robert S. Joyce, Ogden; Howard P. Kirtley, Salt Lake City; Horace G. Merrill, Provo; George W. Middleton, Green River; Edwin M. Nehner, Castlegate; E. G. Peterson, Logan; Joseph A. Phipps, Tooele; Charles C. R. Pugmire, Morgan; Matthew S. Reay, Randolph; Ezra C. Rich, Ogden; J. E. Talmage; J. A. Widtsoe, Salt Lake City, and C. A. Broadas, Delta.

WISCONSIN

Gifts to Medical School.—The medical library of the late John L. C. Cronyn, Buffalo, consisting of 1,000 volumes, has been donated to the library of Marquette University School of Medicine, Milwaukee, by the Cronyn family.

Anthrax in Milwaukee.—The first case of anthrax in human beings to be reported in Milwaukee was recently isolated by Health Commissioner Lewis J. Daniels in South View Hospital. The patient is a hide stripper in a tannery.

Women Elect Officers.—At the annual meeting of the Wisconsin Medical Women's Association, October 2, Dr. Irene Stemper, Oconomowoc, was elected president; Dr. Ada B. Chambler, Milwaukee, vice president, and Dr. Belle P. Nair, Winnebago, secretary-treasurer.

Sanatorium Almost Ready.—The first private charitable tuberculosis sanatorium in the state, founded by the Madison Anti-Tuberculosis Society, will be ready to receive patients by November 15. The sanatorium is located on a wooded slope overlooking Lake Waubesa, and will accommodate at present thirty patients. The buildings were donated by Dr. Charles H. Vilas, Madison. Dr. Louis R. Head, Madison, is president of the association.

Chiropractic Treatment Not Acceptable.—The Wisconsin commission having in charge the enforcement of the workmen's compensation law has held that chiropractic treatment does not constitute "medical and surgical treatment." Sylvester Jones, Janesville, was injured last February while in the employ of Sanford Severhill, both parties being under the compensation. Severhill held compensation insurance with the Employees' Mutual Liability Insurance Company. For a time Jones was treated by a physician, but later of his own volition changed to a chiropractor. The decision of the commission is that Jones is not entitled to reimbursement for the chiropractor's charges under the terms of the compensation law, which requires the employer to furnish "medical and surgical treatment."

CANADA

Deserved Promotion.—Col. Henry R. Casgrain, Windsor, who recruited Canadian Station Hospital No. 3, has been promoted to senior officer of Hospital No. 8, which is now in France. Colonel Casgrain, who had been invalided home, has left for France to assume his new duties.

Medical Board at Work.—The traveling medical board, consisting of Dr. Clarence H. Brown, Ottawa, and Dr. Stock, Toronto, and Dr. James H. McGarry, Niagara Falls, to examine all men eligible for the first draft under the military service act, commenced work at Niagara Falls, October 12, and will continue until all widowers and married men without children have been examined.

GENERAL

Soo Line Physicians Elect Officers.—At the annual meeting of the Minneapolis, St. Paul and Sault Ste. Marie Railway Surgical Association, held in Chicago, October 22 and 23, under the presidency of Dr. John M. Dodson, Chicago, the following officers were elected: president, Dr. George M. Steele, Oshkosh, Wis.; vice president, Dr. David C. Pierpont, Ironwood, Mich., and secretary-treasurer, Dr. John H. Rishmiller, Minneapolis (reelected). Minneapolis was selected as the next place of meeting.

Warning.—A warning has been received from Milwaukee regarding a young man who calls himself Joseph C. Grimble, who gives a history of military experience in France and Belgium, where he says he was seriously wounded and was under the care of Dr. Alexis Carrel. He has scars on the hip and scrotum, has some shortening of the right leg, is about 5 feet, 5 inches in height, 127 pounds in weight, and fair complexion. It is reported that he is an impostor, and is attempting to obtain money under false pretenses.

Formulation of Milk Ordinance.—To assist communities in making their milk supply safe, the United States Department of Agriculture has issued a "Guide for Formulating a Milk Ordinance." This document, *Department Bulletin 585*, suggests a form of ordinance designed to protect the community against fraud and disease, and to insure cleanliness in the production and handling of milk. Health officers and physicians interested in improving milk supplies may obtain copies of this bulletin free, on application to the department.

Campaign of Washington State Medical Association Against Venereal Diseases.—The Committee on Venereal Prophylaxis of the Washington State Medical Association is furnishing to the soldiers and sailors of that state a printed slip on the subject of venereal diseases. Prophylactic stations have been established at the Municipal Dock, Tacoma, and in the Joshua Green Building, Seattle. These stations are manned by an army personnel. The committee is assisted by furnished rooms and equipment, and the circulars which the military authorities aid in distributing.

Personal.—Dr. Augustine M. Fernandez-Yberra, for the last eight years a practitioner of Havana, sailed for Europe, October 29, as traveling correspondent for England, Switzerland, Italy and Spain, for the Havana journal *El Dia*.——Lieut. Percy G. Hamlin, M. R. C., U. S. Army, Richmond, Va., who was on duty with the British troops on the western front, was wounded, October 5.——Lieut. Archibald F. Graham, M. R. C., U. S. Army, Paterson, N. J., on duty with the British forces, has been seriously wounded in the thighs.——Lieut. Clement A. Fogerty, M. R. C., U. S. Army, Philadelphia, who went to England early in August, has been made assistant surgeon in the Southwark Hospital, London.

PARIS LETTER

Paris, Oct. 11, 1917.

The War

THE CABINET OFFICIAL IN CHARGE OF THE ARMY MEDICAL DEPARTMENT

A decree recently appeared in the *Journal Officiel* setting forth the powers of the undersecretary of state for the Service de santé militaire. They are as follows: Article 1. The undersecretary of state has charge of the Service de santé, and directs the activities of this service by and for the state war department. Propositions of every nature concerning the personnel of this service are discussed and prepared in concrete form by him before they are presented to the minister for his consideration. Article 2. The undersecretary of state has, within the limits of his powers, the right to use the ministerial signature. He will likewise correspond directly with the commander-in-chief and the regional commander-in-chief.

Donations from the American Red Cross to the City of Paris

The president of the municipal council of Paris received from Mr Beatty, director-general of the American Red Cross, 266,667 francs ($53,333.40) to be divided, with the cooperation of the prefect of the department of the Seine, among the families of the Parisian officers and soldiers who have seen the longest service. The president of the General Council of the department of the Seine received 133,333 francs ($26,666.60) to be distributed under the same conditions to the families residing within the confines of that district outside of Paris.

Donations from the American Automobile Club

The American Automobile Club has sent to the Automobile Club of France 23,140 francs ($4,628) to be given to the Association of French Women (one of the three societies of the Red Cross) for the purpose of purchasing automobile ambulances.

Death of Dr. Alphonse Boissard

We are advised of the death of Dr. Alphonse Boissard, aged 65, honorary obstetrician to the hospitals of Paris. In 1883, he presented to the Faculté de médecine de Paris a thesis which was a classic on the pelvis and perineum from the obstetric point of view. He was chief of the clinic of Pinard, and in 1891 he received the title of accoucheur of the hospitals of Paris. With Budin he held the chair of adjunct professor of the maternity during 1896 and 1897, and in 1898 he was made accoucheur. Among the subjects that occupied his attention must be mentioned, first, provoked or produced abortion. He also gave much thought to evacuation of the uterus in cases of retained dead fetus, and made interesting researches on the bladder troubles of the parturient. He was president of the Obstetrical Society of Paris, of which he was one of the founders.

LONDON LETTER

London, Oct. 16, 1917.

The War

THE WAR MUSEUM AT THE COLLEGE OF SURGEONS

At the Royal College of Surgeons, Sir Alfred Keogh, director-general of the army medical service, opened an exhibition of specimens of military injuries. This has been arranged by the college staff under the supervision of Arthur Keith, and is temporarily housed in the college museum. At the same time Sir George Makins, president of the college, conferred the diploma of honorary fellowship on Sir Alfred Keogh in the presence of a large gathering of the heads of the army and navy medical services and representatives of the medical services of France, Serbia, the United States, and our overseas dominions. The president paid a high tribute to Sir Alfred Keogh's brilliant career and great administrative ability. In replying, Sir Alfred said that John Hunter would have gloried to see that day, for the exhibition was indeed the vindication of his life work. It included specimens sent in by the medical services of the armies of the oversea dominions as well as by the Royal Army Medical Corps, and it was hoped that eventually these would go to the dominions to form the nuclei of pathologic museums there. It was also hoped that out of the superabundance of materials that this war would supply, local museums would be created in some of the military hospitals.

As early as the third month of the war, an army medical committee was constituted to compile the medical history

Thomas Scilles Kennedy, M.D., New Orleans; Tulane University, New Orleans, 1869; professor of pediatrics in the New Orleans Polyclinic; for fifteen years in charge of the Children's Clinic of the Charity Hospital, New Orleans; a Confederate veteran; died at his home about October 20.

James Benjamin Livingston, M.D., West Middlesex, Pa.; Western Reserve University, Cleveland, 1866; aged 87; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; died at his home, October 18, from senile debility.

Thomas Joseph Henry McCormick, M.D., Boston, Mass.; Harvard Medical School, 1900; aged 40; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society; died at his home in Roxbury, Boston, October 10, from heart disease.

Joseph J. Knapp, M.D., Youngsville, Pa.; College of Physicians and Surgeons, Baltimore, 1891; aged 63; a member of the Medical Society of the State of Pennsylvania; a director and vice president of the First National Bank of Youngsville; died at his home, October 19.

John Quincy Adams, M.D., Amesbury, Mass.; Bellevue Hospital Medical College, 1872; aged 67; a member of the Massachusetts Medical Society; a prominent socialist and once candidate for governor on that ticket; died at his home, October 19.

John L. Schoolcraft, M.D., Schenectady, N. Y.; Albany, N. Y., Medical College, 1869; aged 64; a Fellow of the American Medical Association; health officer of Schenectady in 1914-1915; died at his home, October 23, from cerebral hemorrhage.

Owen W. Grubbs, M.D., Harrison, Ohio; Medical College of Ohio, Cincinnati, 1888; aged 57; died at his home, October 23, from the effects of a gunshot wound of the heart, believed to have been accidentally self-inflicted while cleaning his shotgun.

Howard Chew Garrison, M.D., Kansas, N. J.; Hahnemann Medical College, Philadelphia, 1894; aged 53; a member of the staff of the West Jersey Homeopathic Hospital, Camden; died in a hotel in Atlantic City, October 23, from nephritis.

John H. Wood, M.D., Champaign, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 74; a veteran of the Civil War; formerly mayor of Deland, Ill.; died at his home in Champaign, October 18, from malignant disease.

George N. Carnachan, M.D., Bruce, Wis.; Louisville, Ky., Medical College, 1878; aged 60; a Fellow of the American Medical Association; died in the Sacred Heart Hospital, Eau Claire, Wis., October 25, after a surgical operation.

Pitt Harold Jones, M.D., Springfield, Maine; New York University, New York, 1884; aged 55; for two terms a member of the house of representatives of Maine; town treasurer of Springfield; died in his automobile, October 14.

Harry Valentine Sanns, M.D., Le Sage, W. Va.; Medical College of Ohio, Cincinnati, 1880; aged 57; a member of the West Virginia State Medical Association; died in Rochester, Minn., August 16, from carcinoma of the colon.

David McIntyre, M.D., Boston; New York University, New York, 1886; aged 59; a Fellow of the American Medical Association; a well-known obstetrician of South Boston; died at his home, September 2, from diabetes.

Edwin Dorset Newton, M.D., Atlanta, Ga.; Jefferson Medical College, 1869; aged 82; surgeon in the Confederate service during the Civil War; died at the home of his sister in Athens, Ga., October 19, from pneumonia.

Elbridge A. Shay, M.D., St. Louis, Mo.; Cleveland University of Medicine and Surgery, 1883; aged 68; professor of anesthesia in the St. Louis College of Physicians and Surgeons; died at his home, October 20.

Mary Darrach, M.D., New York; New York Medical College and Hospital for Women, 1904; founder of the Darrach Home for Crippled Children, New York; died in Atlantic City, October 18, from pneumonia.

William Lewis Tallman, M.D., Chicago; Bellevue Hospital Medical College, 1881; aged 58; died at his home, October 27, from cerebral hemorrhage.

G. H. Clemens Richard, M.D., Cincinnati; Eclectic Medical Institute, Cincinnati, 1856; aged 89; died at his home, October 13.

John Carder Champlin, M.D., Block Island, R. I.; Boston University, 1885; aged 57; died at his home, in August, from nephritis.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

"PATENT MEDICINES" IN CANADA AND THE UNITED STATES

A Comparison of Therapeutic Claims Made in the Two Countries

A little more than five years ago an article was published in this department comparing the labels on certain "patent medicines" that were sold, respectively, in the British Isles and in the United States. It was shown that the federal Food and Drugs Act in this country had increased alike the protection of the purchaser and the veracity of the seller. The present article aims to draw a similar parallel between the claims made for certain "patent medicines" in the United States and in the Dominion of Canada.

The national law in the United States governing interstate commerce in "patent medicine" guards the public by means of two prohibitions that may be briefly expressed in their essentials as follows: It prohibits "false or misleading" statements regarding the composition or source of origin of any drug product; it prohibits, also, "false and fraudulent" claims for therapeutic effects. The law governing the sale of "patent medicines" in Canada prescribes certain regulations for labeling, and specifically prohibits the use of cocain in any "patent medicine." It does not, however, offer any protection to the Canadian public against false, misleading or fraudulent claims that may be made for products of this class.

DODD'S KIDNEY PILLS IN CANADA

A POSITIVE CURE FOR ALL KIDNEY DISEASES.

CURES BACKACHE	CURES-RHEUMATISM	PURIFIES THE BLOOD
HEADACHE	BRIGHT'S DISEASE	CLEANSES THE SYSTEM
INDIGESTION	DIABETES	CURES-FEMALE WEAKNESS

DODD'S KIDNEY PILLS IN THE UNITED STATES

A TREATMENT FOR KIDNEY DISEASES.

FOR-BACKACHE	FOR-RHEUMATISM	FOR-FEMALE WEAKNESS
HEADACHE	URINARY AND	PURIFYING THE BLOOD
INDIGESTION	BLADDER TROUBLE	CLEANSING THE SYSTEM

What follows is not to be construed in any sense as a criticism of the Canadian law; the object of the comparisons made is to show that so far as curative claims for "patent medicines" are concerned, Canada is in the same position that the United States was before the passage of the federal Food and Drugs Act, June 30, 1906. Manufacturers of "patent medicines" who wish to sell their preparations in Canada are under no legal restrictions as to the claims they may make for them. In the United States therapeutic claims—made on the trade package—must be kept within certain limits. If false and fraudulent claims are made the manufacturer lays himself open to prosecution under the federal law. If, then, we find that certain claims are made for a "patent medicine" sold in Canada that are not made for the same product sold in the United States, we are justified in inferring that such claims are in the prohibited list, that is, they are false, misleading or fraudulent.

Within the last few weeks we have had purchased on the open market in Canada certain "patent medicines" that are sold also in the United States. We purpose comparing the claims made on the Canadian trade packages with the claims made for the same products sold south of the international boundary.

DODD'S KIDNEY PILLS

"Dodd's Kidney Pills" were analyzed a few years ago by the chemists of the British Medical Association, who reported that the principal ingredient was potassium nitrate. Other constituents found were baking soda, soap, hard paraffin, wheat flour, powdered turmeric and minute quantities of resins and plant extractives. Practically the same findings were reported by the state chemists of North Dakota in their 1915 *Bulletin*. These pills are sold in Canada under claims which, if made in the United States, would undoubtedly subject the manufacturers to prosecution on the charge of making false and fraudulent statements regarding the therapeutic value of their product. Compare:

CANADA UNITED STATES

Photographic reproduction (reduced) of the labels of "Doan's Kidney Pills" as sold in Canada and the United States, respectively. It is worthy of note that while in Canada (where the law does not prohibit lying on the label) Doan's Kidney Pills are sold as a "cure" for Bright's disease and diabetes, in selling their pills in the United States the manufacturers specifically state that the pills "are not recommended for Bright's disease or diabetes."

CANADA	UNITED STATES
"A Positive Cure for all Kidney Diseases—Cures—Backache, Headache, Indigestion. Cures—Rheumatism, Bright's Disease, Diabetes. Purifies the Blood Cleanses the System. Cures — Female Weakness."	"A Treatment for Kidney Diseases — For — Backache, Headache, Indigestion. For—Rheumatism, Urinary and Bladder Trouble. For—Female Weakness, Purifying the Blood, Cleansing the System."
"*Bright's Disease*— . . . Dodd's Kidney Pills is the only remedy that has cured Bright's disease."	"*Bright's Disease*—" (Statement omitted — no claim made that Dodd's Pills are of any value in this disease).
"Diabetes— . . . Dodd's Kidney Pills will cure this disease."	(No reference whatever to diabetes.)
". . . Dodd's Kidney Pills will cure any form of heart disease."	(No reference whatever to heart disease.)
". . . are the only cure for kidney disease."	(No such statement anywhere.)
". . . the best kidney remedy obtainable."	(No such statement anywhere.)

Every one must admit that the claims made for the therapeutic action of Dodd's Kidney Pills in the Canadian package are stronger and better "business pullers" and "selling copy" than the much more conservative claims made in this country. Now, if Dodd's Kidney Pills are "a Positive Cure for all Kidney Diseases"; if they really are "the only remedy that has cured Bright's disease"; if they will "cure diabetes" and "cure any form of heart disease," and are, in fact, "the only cure for kidney disease," why does not the manufacturer of these pills so state on the trade packages sold in the United States? There is no law against telling the truth.

DOAN'S KIDNEY PILLS

"Doan's Kidney Pills" also have been analyzed by the chemists of the British Medical Association, who reported finding oil of juniper, hemlock pitch and powdered fenugreek, as well as potassium nitrate—the latter, in spite of the claim made in the British Isles (and also in Canada), that these pills were "purely vegetable." The state chemists of Connecticut also have analyzed these pills and reported that their active ingredients appear to be potassium nitrate, pitch and possibly a trace of oil of juniper and other unidentified organic drugs. In Canada Doan's Pills are "a specific for kidney complaints," but in the United States the manufacturer more conservatively—or cautiously—mentions merely that they are "for kidney complaints." Again comparing:

CANADA	UNITED STATES
"Doan's Kidney Pills, A Specific for Kidney Complaints and all diseases arising from disorder of the Kidneys & Bladder Cure Backache, Weak Back, Rheumatism, Diabetes, Congestion of the Kidneys, Inflammation of the Bladder, Gravel, Bright's disease, Scalding Urine and all Urinary troubles, Cleanse the System, Purify the Blood."	"*Doan's Kidney Pills for Kidney* Complaints and diseases arising from disorders of the Kidneys & Bladder, such as Back-ache, Weak Back, Dropsy, Congestion of the Kidneys, Inflammation of the Bladder, Scalding Urine and Urinary troubles."
"These Pills are composed of rare and valuable medicinal agents. . ."	(No such claim made.)
". . . will absolutely cure backache, all forms of Kidney Disease, Diabetes, Bright's Disease, etc."	". . . are not recommended for Bright's disease or diabetes."
". . . a purely vegetable medicine. . ."	(No such claim made.)

Every physician and many an intelligent layman knows that neither Doan's Kidney Pills nor any other drug "will absolutely cure . . . all forms of kidney disease, diabetes, Bright's disease, etc." This statement is a preposterous falsehood on its face, but the manufacturers of Doan's Kidney Pills have made it where there is no legal restriction on lying, although in the United States they emphasize specifically that their pills "are not recommended for Bright's disease or diabetes" and add: "Both these are serious disorders and the patient should be under the supervision and instruction of a competent physician."

If Doan's Kidney Pills really contain "rare and valuable medicinal agents," as is claimed in the Canadian trade package, there is no law in the United States that would prohibit the manufacturer from saying so. There is, however, a law that specifically prohibits false or misleading statements regarding the composition of drug products. In view of the fact that the claim of "rare and valuable medicinal agents" is omitted from the trade package in the United States, the inference is fairly obvious.

CANADA UNITED STATES

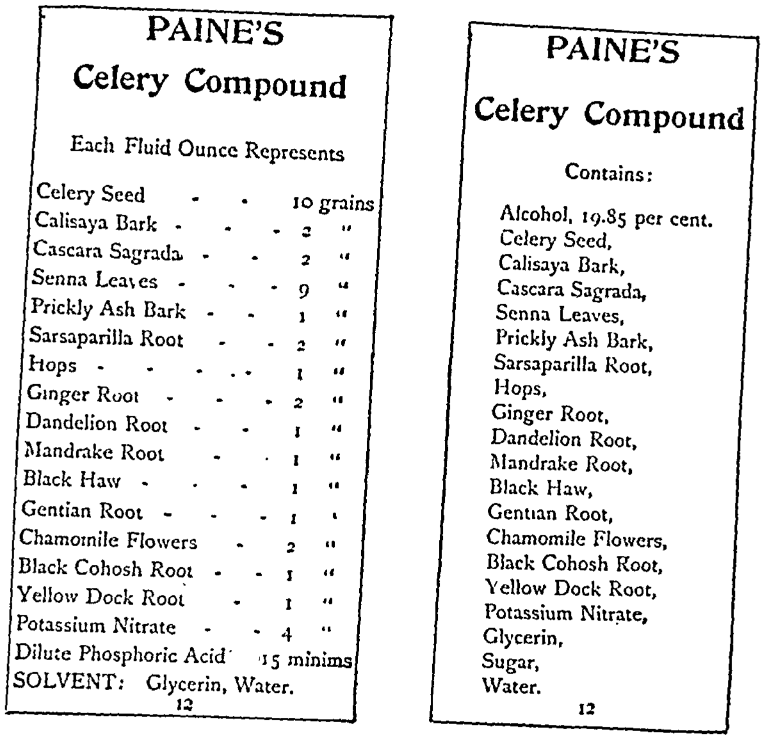
Photographic reproduction (reduced) of the labels of "Williams' Pink Pills" as sold in Canada and the United States, respectively. Notice that the Canadian public is told that these pills will "cure" all nervous diseases, locomotor ataxia, paralysis, female weaknesses, etc. The same pills when sold in the United States are not invested with such marvelous powers.

WILLIAMS' PINK PILLS FOR PALE PEOPLE

"Dr. Williams' Pink Pills for Pale People" are a much over-advertised proprietary modification of the common Blaud's pill. The manufacturers have been found guilty in the United States courts of making false and fraudulent claims for their product in reckless and wanton disregard of their truth or falsity for the purpose of defrauding purchasers. Let us compare the claims made today for Pink Pills in the United States with those made for the same product in Canada:

CANADA	UNITED STATES
"Cures Anemia, all Nervous Diseases, Locomotor Ataxia, Paralysis, Rheumatism, Sciatica, Headache, all Female Weaknesses, Suppressions of the Periods, Pale and Sallow Complexions, all Diseases arising from Mental Worry, Over-Work, Excess, Early Decay, Etc."	"For Anemic Conditions, Diseases Caused by or Dependent upon Thin, Impoverished Blood and for Nervous Disorders resulting from Mal-Nutrition. Useful wherever a nervine or digestive tonic is required.
"This wonderful remedy is offered to the public . . ."	"These pills are offered to the public. . . ."
"Dr. Williams' Pink Pills also invigorate the Blood. . . ."	"Dr. Williams' Pink Pills are designed to invigorate the Blood . . ."
"Suppression of the Menses. .	(Omitted.)
"Locomotor Ataxia . . ."	(Omitted.)

It is worthy of note that while the claims now made in the United States, as quoted above, are more conservative than those on which the government charged the company with fraud, yet the claims on which the company was found guilty of fraud were not nearly so positive and blatant as those quoted above as being made today for the Canadian product.



PAINE'S

UNITED STATES

Photographic reproduction (reduced) of page 12 from the booklets accompanying the bottles of Paine's Celery Compound as sold, respectively, in Canada and the United States. It will be seen that the only ingredient whose quantity is given the public in the United States is the alcohol—which the law demands. In Canada, where the law does not demand it, the presence of alcohol is not mentioned, although the alleged quantities of the other ingredients are given. Canadian officials state that an analysis of Paine's Celery Compound on sale in Canada disclosed the presence of over 16 per cent. alcohol. The Canadian public would be justified in assuming from the alleged formula published that the stuff contained no alcohol but that the solvents used were glycerin and water.

PAINE'S CELERY COMPOUND

"Paine's Celery Compound" belongs to the "bracer" type of nostrums; that is, it is a preparation whose most potent and active drug is alcohol. Some years ago it used to be one of the most widely advertised of "patent medicines." The concern, apparently, had testimonials galore, many of them from individuals whose ability along certain special lines was as great as their ignorance of the nature, cause and treatment of disease was abysmal. According to one of the old advertising booklets sent out by manufacturers of Paine's Celery Compound, Sarah Bernhardt was "convinced that it is the most powerful nerve strengthener that can be found," while "Edward L. Preetorius, Manager of the *Westliche Post*" considered this medicated booze "the only remedy that will restore the nerves which have been shattered by overwork, worry or business cares." The same booklet declares that "Rev. Zephaniah Meek, D.D., Editor of the *Central Methodist*," had used several bottles "with immediate effect as well as permanent benefit." Especially significant of the way in which the public was fooled in those days before the presence and amount of alcohol had to be declared on the labels was the alleged testimonial of "Francis Murphy, Founder of the Blue Ribbon Movement," who endorsed Paine's Celery Compound as "a splendid remedy."

UNITED STATES

Photographic reproduction (reduced) of the labels of "Paine's Celery Compound" as sold in Canada and the United States, respectively. Note that the claims made on the Canadian label that this nostrum "strengthens," "restores," "invigorates" and "relieves" are absent from the label used in the United States.

These are but a few of the endorsements of Paine's Celery Compound published in the good old days. The claims made today on the trade package as it is sold in the United States, are relatively conservative and innocuous. A booklet that comes around the bottle gives a list of drugs that are said to enter into the composition of this nostrum. No quantities, however, are vouchsafed (in the United States) except that of the one ingredient which the law requires to be made public, namely, alcohol, of which it has 19.85 per cent. The list gives fifteen vegetable drugs and, in addition, potassium nitrate, glycerin and sugar. As the state chemists of Connecticut, who have analyzed the stuff, point out, the list of these fifteen vegetable drugs "loses much of its impressiveness when it is seen that the total amount of vegetable extractives is less than 1.5 per cent." Much more impressive is the nearly 20 per cent. alcohol! The booklet accompanying the Canadian trade package also contains a list of the alleged ingredients. This list differs from that found in the packages sold in the United States in that it contains a quantitative statement of the various drugs listed! It tells how many grains of each of the fifteen vegetable drugs are represented in each fluidounce of Paine's Celery Compound; also it tells the amount of potassium nitrate. But one thing it does *not* tell—the amount of alcohol! In fact, it does not even admit that the Canadian product contains any alcohol! On the other hand, it emphasizes the alleged fact that the "solvent" in the Canadian product is glycerin and water; also it mentions that in each fluidounce there are 15 minims of dilute phosphoric acid, a drug whose presence is not mentioned in the product sold in the United States. As Paine's Celery Compound without alcohol seemed almost as much of an anomaly as *Hamlet* with Hamlet left out, we wrote to the Inland Revenue Department of Canada calling attention to these facts. The Inland Revenue Department replied that Paine's Celery Compound, as sold in Canada (giving no information regarding the amount or even the presence of alcohol), had been examined and, as a result, alcohol (over 16 per cent. by volume) *was* found, while phosphoric acid could not be detected!

The claims in the trade package of Paine's Celery Compound as sold, respectively, in Canada and the United States varied thus:

CANADA	UNITED STATES
Solvent: "Glycerin, Water."	Alcohol, 19.85 per cent.
"A True Nerve Tonic, an Active Alterative, a Reliable Laxative and Diuretic. It Restores Strength, Renews Vitality, Purifies the Blood, Regulates the Kidneys, Liver and Bowels."	(Omitted entire.)
"A Reliable Medicine for general nervous debility and diseases arising from a debilitated nervous system. A powerful Alterative and Diuretic; a Valuable Remedy for Dyspepsia, Biliousness, Constipation, Piles, Liver Complaint, Neuralgia, Rheumatism, Fever and Ague, and Kidney Trouble; also Female Complaints, and diseases arising from an impure state of the Blood. It acts at the same time as a tonic, reviving the energies and spirits, making it one of the best medicines in existence for aged people."	(Omitted entire.)
"The Great Remedy for Nervous Diseases, Neuralgia, Rheumatism, Nervous Debility, Biliousness, Dyspepsia, Constipation, Piles, Liver Complaint, Kidney Troubles, Female Complaints, and Diseases Arising from Impure Blood."	"Recommended by the Proprietors for Nervous Debility, Dyspepsia, Neuralgia and Rheumatism."

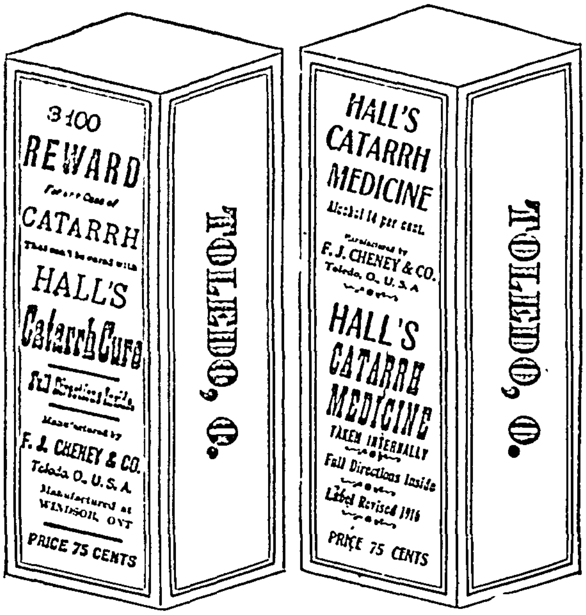
From a comparison of the old advertising in our files, it seems that the people of Canada are being served with claims for Paine's Celery Compound of the vintage of '98.

HALL'S CATARRH MEDICINE

"Hall's Catarrh Cure" (Canada), or "Hall's Catarrh Medicine" (United States), was found, by government chemists, to contain more than 13 per cent. alcohol, over 10 per cent. potassium iodid, 3 per cent. of sugar and a small amount of some bitter extract, probably gentian, with small quantities of cardamom and caraway and water. This nostrum has for years used an obviously false name ("Hall's Catarrh Cure"). Finally the state of Nebraska declared the stuff misbranded because of the use of the word "cure." The company took an appeal, but before the matter reached the Appellate Court apparently changed its mind and asked for a dismissal of the appeal, expressing at the same time its purpose of changing the name of its preparation to "Hall's Catarrh *Medicine*." The difference in the claims on the trade packages in Canada and the United States may briefly be shown:

CANADA	UNITED STATES
"Hall's Catarrh Cure."	"Hall's Catarrh Medicine."
(No alcohol declared.)	"Alcohol 14 per cent. 3 ounces."
"$100 Reward For any Case of Catarrh That Can't be cured with Hall's Catarrh Cure."	(No reward offered.)

The "offer" of this concern, to pay $100 for any case of "catarrh" that the nostrum fails to cure, has been made for many years. One case has been recorded of an individual who, after taking twenty-six bottles of the stuff, wrote to the nostrum company telling them that instead of being benefited he felt worse and asked them either to refund his money or to pay him the hundred dollars in accordance with their "offer." He, of course, got neither; the company said that he had not taken enough to give the medicine a fair chance! The exploiters still make this "offer" in their newspaper advertising in the United States, but have eliminated it from the trade package. It is significant that the federal law does not control claims made elsewhere than on the trade package. In Canada, as the quotations above show, the hundred dollar "offer" still appears on the trade package.



CANADA — UNITED STATES

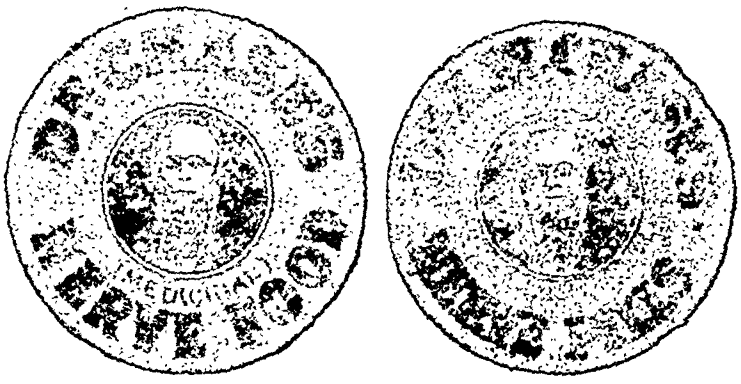
Photographic reproduction (reduced) of the labels of "Hall's Catarrh Medicine" as sold in Canada and the United States, respectively. Comparison of the labels shows that the presence and amount of alcohol is admitted where the law demands it (in the United States), but no mention is made of it in Canada. While the stuff is called a "cure" in Canada, where there is no penalty for false and fraudulent therapeutic claims, it is a "medicine" in the United States. In the United States also the "$100 Reward" does not appear on the trade package.

HOOD'S SARSAPARILLA

Like most of the so-called sarsaparillas, Hood's nostrum is an alcoholic solution of vegetable extractives and potassium iodid. The difference in the claims made in Canada and the United States are shown:

CANADA	UNITED STATES
"Contains 18 per cent. alcohol. The smallest quantity that will extract and preserve all the remedial properties of the ingredients."	"Contains 16½ per cent. alcohol. Used only as a solvent and preservative. This is a concentrated medicine, to be taken only in small doses, according to the directions enclosed."
"The Great Blood Purifier and Tonic, for Eradicating Scrofula, Scrofulous Sores and all Scrofulous Diseases, and for Purifying, Enriching and Vitalizing the Blood and Restoring and Renovating the whole system."	(Omitted.)

It will be noticed that the Canadian product contains 18 per cent. alcohol which the manufacturers declare is "the smallest quantity that will extract and preserve all the remedial properties of the ingredients." The stuff sold in the United States under the same name contains only 16.5 per cent. alcohol. Is it to be inferred that some of the "remedial properties" are lacking?



CANADA UNITED STATES

Photographic reproduction (reduced) of the labels of "Dr. Chase's Nerve Pills" as sold, respectively, in Canada and the United States. Chase's Nerve *Pills* use to be a "Nerve *Food*" in the United States—but *that* was before there was a law penalizing falsehood.

DR. CHASE'S NERVE PILLS

This somewhat insignificant humbug used to be called "Dr. Chase's Nerve Food" before the federal Food and Drugs Act made falsifying expensive. Then "Food" became "Tablets" and still later "Pills." It is still a "Food" in Canada. Compare:

CANADA	UNITED STATES
"Dr. Chase's Nerve Food."	"Dr. A. W. Chase's Nerve Pills."
"Builds up the system, Cures Thin and Watery Blood, Nervous Prostration, Brain Fag, Nervous Headache, Female Trouble, Pale & Sallow Complexion, Heart Failure, Dizziness & Fainting, Sleeplessness and General Weakness."	"Used in the Treatment of Thin and Watery Blood, Nervous Prostration, Brain Fag, Nervous Headache, Nervous Dyspepsia, Pale & Sallow Complexion, Irregular Heart Action, Dizziness & Fainting, Sleeplessness and General Weakness."
". . . makes it impossible for the following diseases and symptoms of diseases, to exist. . . ."	". . . make it next to impossible for the following diseases and symptoms of diseases, to set in: . . ."
". . . this great food cure . . ."	". . . this great nerve medicine. . . ."
"There is no preparation known which will so quickly create new, rich blood. . . ."	"There is no preparation known which will more quickly create new, rich blood. . . ."

It will be seen that, aside from the change in the name of the product, the difference in the claims is essentially the difference between the "lie direct" and the "lie with circumstance."

CANADA UNITED STATES

Photographic reproduction (reduced) of the labels of "Gino Pills" as sold, respectively, in Canada and the United States. Of course, gin cannot be put up in pill form and, therefore, it would be a violation of the United States Food and Drugs Act to sell this nostrum as "Gin Pills."

GINO PILLS

While it is obviously impossible to put up brandy, whisky or gin in pill form, one finds on the Canadian market "Gin Pills" which are recommended "*for the kidneys.*" The same preparation sold in the United States is not, of course, called "Gin Pills," as that would at once bring the manufacturers in conflict with the federal law prohibiting false or misleading statements regarding composition. Here we find them as "Gino Pills for the Kidneys." The variations in claims made for these pills in Canada and the United States, respectively, are not especially striking, but are nevertheless worthy of the study of those interested in truthful advertising:

CANADA	UNITED STATES
"Gin Pills for the Kidneys."	"Gino Pills for the Kidneys."
"The various ingredients composing the *formulae* are the best known to the medical profession . . ."	"The various ingredients composing the formulae are among the best known to the medical science . . ."
"For this purpose (laxative) there is nothing better than the National Lazy-Liver Pills."	"For this purpose (laxative) we know of nothing better than National Lazy-Liver Pills."

SUMMARY

The nostrums to which we have called attention are not the only ones whose varying claims in Canada and the United States have been examined. They are, however, sufficient to bring out these facts: The "patent medicine" industry as a whole is founded on falsehood; misleading and false claims will be made for such preparations, at least in the majority of cases, just so long as the manufacturers are subject to no restraint except their own consciences. As has been shown time and again in these pages, nostrum exploiters in the United States have greatly modified the claims for their products as such claims appear on the trade packages, because federal and state laws have provided penalties for falsehood and fraud. These same manufacturers have continued to falsify and mislead in those avenues of publicity (newspapers, etc.) which are not subject to legislative restraint. The same manufacturers have continued to falsify even on their trade packages in Canada where there is no law prohibiting it.

The "patent medicine" interests in the United States have complained loudly and frequently that their business has been and is unduly hampered by legislation. They have insisted that while it was admitted there were certain concerns in their line of business that were not above criticism, the business as a whole was no worse than any other industry. Unfortunately for them and still more unfortunately for the public, these protestations of innocence are not borne out by facts. Even a cursory study of the "patent medicine" problem will show that while in occasional and rare instances a "patent medicine" manufacturer will voluntarily modify his statements and temper his claims, in general, the "patent medicine" industry is just as dishonest as it dares be.

Garbage.—New York's garbage, by treatment in a $3,000,000 recovery plant of the latest type, yields grease for 70,000,000 cakes of soap; 1,500 tons of nitrogen; 2,000 tons of phosphoric acid, 500 tons of potash. With the nitrogen, and the glycerin from soap making, there is a recovery of material yielding 3,500,000 pounds of high explosives, while the phosphoric acid and potash, as well as the nitrogen, are valuable in the making of commercial fertilizers. This plant operating under the so-called Cobwell process, which treats garbage almost entirely by chemical methods, has effected increased recoveries of valuable products amounting to at least 25 per cent. more than recoveries under the best previous reduction methods used for New York's garbage. In soap, for instance, there is an additional recovery of grease for 10,000,000 cakes a year, and in high explosives material for 700,000 pounds. The chemical treatment followed not only eliminates all odors incident to the old boiling process, by which garbage was cooked for a long period in water, but saves many of the rich chemical elements which were formerly lost. Under the old process it is said a large percentage of these elements were cooked into a rich soup, and then the soup was thrown away. Moreover, a considerable percentage of grease was burned by the high temperature driers used before degreasing, and the cooking process had a splitting effect on the material which led to considerable losses of glycerin. The new process saves these. The plant is more expensive to install, but much more economical in operation.—*Weekly Bulletin.*

CORNEAL TATTOOING

To the Editor:—I notice in The Journal, Oct. 27, 1917, p. 1420, an article by F. H. Verhoeff of Boston on a substitute for tattooing the cornea with India ink for the purpose of obliterating white corneal scars, etc. His method consists in injecting a solution of India ink into the layers of the cornea by means of a hypodermic syringe. Never having tried this method, I am not in a position to criticize it; but it seems to me that it is not at all an ideal procedure. I have for years abandoned the old method of tattooing the cornea with needles and India ink. This procedure is undoubtedly satisfactory when skin tattooing is under consideration, but it is not at all satisfactory for corneal tattooing. It requires a good deal of force to thrust the needles into the cornea, and then when this is done the black stain produced by each needle is very minute, and the needles have to be thrust in over and over and over again, and even then a large area of the cornea will be left untattooed.

My method of tattooing the cornea is extremely simple. I merely take a cataract knife and scrape off the corneal epithelium where I desire to produce a black stain. This can be done with great accuracy, and is especially useful when we wish to produce a round stain simulating a pupil. Having scraped off the corneal epithelium with the exactness which is possible with this procedure, I then rub into the cornea a thick emulsion of the India ink with a little cotton tightly twisted on a toothpick or cotton holder. This is done thoroughly several times in order to force the ink to soak into the tissues. The eye is not closed for about ten minutes in order to give the ink an opportunity to stain the tissues. The usual postoperative dressings are then made. Of course, a certain amount of this stain will wear off, and it may be necessary to repeat the little operation in a few days or weeks until a good India ink stain is produced. Still, I have seen several cases in which only one treatment was necessary, and I do not remember having done it more than twice. Naturally, in the course of a year or two it is sometimes necessary to give the cornea another India ink staining.

This method of staining the cornea is simple, efficacious and accurate. It has always given satisfactory results, and is a procedure to be recommended.

Frank Allport, M.D., Chicago.

"SCIENCE"

To the Editor:—May I be permitted to correct a misstatement regarding the teachings of Christian Science which appeared in your issue of October 13 under the caption "Science," namely, that "for the Christian Scientist, germs do not exist; the tubercle bacillus is but a creature of the medical man's disordered fancy." Christian Science does not teach that germs exist only in the mind of the medical man. It teaches that disease, like physicality itself, is in the realm of false belief, and that is where it needs to be corrected or "cured" and not by something administered to the body. The Journal appears to consider such teaching as worthy only of a sneer; but it should not be forgotten that the profession, as a whole, is granting a constantly increasing importance to mental causes, such as fear, in the production even of germ diseases.

Our critic implies that to look through a microscope and see a germ settles the question between medicine and Christian Science in favor of the doctor. Of course it does not, any more than to bruise your knuckles on a stone floor settles the question as to materiality of matter. In spite of the bruised knuckles, the modern physicist insists that the "material" atom is a mass-point of force—absolutely unmaterial. In other words, another case of false belief. In the same way and for similar reasons the Christian Scientist, in spite of the microscope, is convinced that disease, like all evil, is the product of the human mind.

Christian Scientists and the medical profession do not agree as to what the mental factor is in a disease such as tuberculosis, but the profession would no longer contend that it is nothing.

Avery Coonley, Committee on
Publication for Illinois, Chicago.

[Comment.—As most of our readers probably know, Mrs. Eddy's followers have what is possibly the most alert press bureau of any organization in the world. Every article that can in any way be construed as a criticism of "Christian Science" is answered by the "Committee on Publication." Mr. Coonley's letter is of this class.

The mental processes of the professional "Christian Scientist" are so hopelessly awry that one must despair of answering the casuistic arguments offered. Mr. Coonley's letter would indicate that his sect believed that the medical profession took no account of the mental element in the treatment of disease, although, of course, it knows perfectly well that applied psychotherapy antedated not only Mrs. Eddy but Quimby also, by many centuries.

The statements in the letter above to the contrary notwithstanding, it *is* a fact that to Christian Scientists "the tubercle bacillus is but a creature of the medical man's disordered fancy"—in the sense, obviously meant in our editorial, of being the immediate and proximate cause of tuberculosis. The letter admirably illustrates the loose and illogical modes of thought employed by Mrs. Eddy's professional followers. Mr. Coonley points to the physicist's philosophical definition of matter as "a mass-point of force" as proof of the unmateriality of matter, and insists that bruising one's knuckles on a stone floor does not settle "the question as to the materiality of matter." To most normal intellects it *does* most effectively settle the question. Nor are "Christian Scientists" themselves averse to coming "down to earth" in certain phases of their "healing" activities. It is a matter of common observation and frequent comment that while Mrs. Eddy's followers insist that disease is wholly a "question of mind," they are by no means averse to being paid for their "treatments" by those conglomerations of "mass points of force" which, in the parlance of the unregenerate, are known as material dollars.—Ed.]

THE ETIOLOGY OF SCURVY

To the Editor:—I have read the editorial on this subject in The Journal (Sept. 1, 1917, p. 728), and think that my experience here may be of interest, as I treated about 3,000 cases in the year 1915.

This island lies in the Caribbean Sea close to and north of Venezuela, and the climate is very dry, there being only a few months a year in which it rains. The food of the poorer and laboring people consists chiefly of small or Guinea corn, corn meal, fish, generally salted, and a small amount of goat or sheep meat, fresh or salted and dried. In a normal year between April and November there are practically no green vegetables to be had except the small amount imported, which is hardly sufficient to supply the richer persons in the town. In a year of drought not only do the people suffer from a lack of green vegetables and fruit but all the rain water becomes exhausted, and then they must drink water from wells that are more or less brackish. During the years 1912, 1913 and 1914, so little rain fell that the people were unable to get any crops. Being helped by the government and by working in the mines and aloes plantations, they were able to buy enough corn meal to keep from starving, but they suffered greatly from scurvy.

That scurvy is probably a disease caused by the lack of some necessary substance contained in fresh vegetables and fruit is shown by the following observations:

The greatest sufferers were the people in the districts in which the food consisted almost entirely of corn meal.

The richer class living in the same districts under the same conditions but who were able to afford fresh vegetables and fruit did not show any symptoms of scurvy.

Lime juice helped to prevent and to cure.

As soon as the rains came and the people were able to get fresh vegetables, the scurvy disappeared.

This year has also been very dry; and although the people of the outlying districts have had good drinking water, they have not had any fresh vegetables for months, and I am again beginning to see patients with symptoms of scurvy. I have observed that those who have had scurvy are more susceptible to it.

George R. Hopkins, M.D., Aruba, Dutch West Indies

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ANTITYPHOID INOCULATION

To the Editor:—The statement has been made that during the Boer War there was at least a certain amount of antityphoid inoculation employed, and that in spite of this there was a large incidence of typhoid fever among the English troops. Can you give me any information as to the truth or error of this statement, or refer me to any medical literature from which I can gain such knowledge?

Winfred Overholser, M.D., Westboro, Mass.

Answer.—In the Boer War, according to the Antityphoid Commission Report made to the Army Medical Department of Great Britain in 1913, an extended trial of antityphoid inoculation was made by Sir Almroth E. Wright. The inoculation was voluntary, and there are official records of the inoculation of 14,626 men out of a total strength of 328,244 men who served during the three years of the war. "Owing to the difficulties of obtaining accurate statistical information, which appears to be inseparable from active service in the field, the evidence in the case of typhoid vaccine and its power to protect against attack proved disappointing, and it was only in certain units that the material was of sufficient homogeneity to be of value."

Dr. Wright believed that the extent of the disease was diminished about one-half, and that the mortality was favorably influenced to an even greater extent. At that time the cultures were heated to 60 C. in order to destroy their vitality. It has since been shown that this amount of heat injures or destroys to a great extent the power of the vaccine to produce a good response in the formation of those substances on which the body depends for its protection. According to Rosenau (Preventive Medicine and Hygiene), in 1900, during the Boer War, Wright, together with Leishman, prepared a vaccine and supervised the inoculation of 100,000 British troops. The results in India were quite encouraging, but for various reasons, the same procedure in South Africa was not as satisfactory as had been anticipated. Leishman explains the lack of success by saying that the vaccine may have been made less efficient by the use of too great heat in killing the bacilli.

In a recent address before the Clinical Congress of Surgeons, as reported in The Journal last week, Sir Berkeley Moynihan said that 98 per cent. of English soldiers have been voluntarily inoculated against typhoid, with the result that they have had only 292 deaths from that disease and only 6,022 cases altogether, whereas in the South African War they had 57,684 cases with over 8,000 deaths, although the present army, infinitely larger, is living under much more difficult circumstances.

SHOTGUN VACCINES FOR "COLDS"

To the Editor:—Has there been work done of sufficient extent to be of value in justifying use of mixed "shotgun" vaccines to abort or immunize "common colds," that is, rhinitis, pharyngitis, acute bronchitis, coryza, etc.?

Charles E. Bennett, M.D., Aneta, N. D.

Answer.—We know of no investigation which demonstrates that the use of the commercial mixed vaccines are of value in the prevention or treatment of "common colds" or of similar affections. The Council on Pharmacy and Chemistry accepts for New and Nonofficial Remedies mixed vaccines only on condition that their usefulness has been established by acceptable clinical evidence; so far it has not admitted any of the "influenza" or "catarrhal" mixed vaccines.

SALARY AND ALLOWANCES OF M. R. C. OFFICER

To the Editor:—1. If a physician with a dependent wife enlists in the Medical Reserve Corps, is any allowance made for his wife aside from his regular salary

2. When a physician accepts a commission, does his salary date from the time of his acceptance or from the time he is actually called into service or training?

C. M. Murrell, M.D., Matherville, Ill.

Answer.—1. No.

2. An officer's salary commences on the day on which he reports for active duty. He is on active duty when he goes into training.

COMING EXAMINATIONS

Arkansas: Little Rock, Nov. 13-14. Sec., Dr. T. J. Stout, Brinkley.

Arkansas: Eclectic: Little Rock, Nov. 13. Sec., Dr. C. E. Laws, 803½ Garrison Ave., Fort Smith.

Connecticut: New Haven, Nov. 13-14. Sec., Dr. Charles A. Tuttle, 196 York St., New Haven.

Connecticut: Homeopathic: New Haven, Nov. 13. Sec., Dr. E. C. M. Hall, 82 Grand Ave., New Haven.

Connecticut: Eclectic: New Haven, Nov. 13. Pres., Dr. J. W. Fyfe, Saugatuck.

Delaware: Wilmington, Dec. 11-13. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida: Jacksonville, Dec. 4-5. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Kentucky: Louisville, Dec. 4-6. Sec., Dr. A. S. McCormack, Bowling Green.

Louisiana: New Orleans, Dec. 6-8. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Maine: Portland, Nov. 13-14. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Maryland: Baltimore, Dec. 11. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

Massachusetts: Boston, Nov. 13. Sec., Dr. Walter P. Bowers, Room 501, No. 1 Beacon St., Boston.

Missouri: St. Louis, Dec. 17-19. Sec., Dr. George H. Jones, 206 Washington St., Jefferson City.

Nebraska: Lincoln, Nov. 14. Sec., Dr. J. J. Hompes, 612 Security Mutual Life Bldg., Lincoln.

New Hampshire: Concord, Dec. 10-12. Sec., Dr. W. S. Crosby, Beacon Bldg., Manchester.

Ohio: Columbus, Dec. 4-6. Sec. Pro-tem., Dr. Herbert M. Platter, 185 E. State St., Columbus.

South Carolina: Columbia, Nov. 13. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

Texas: Dallas, Nov. 20-22. Sec., Dr. M. F. Bettencourt, Mart.

Virginia: Richmond, Dec. 11-14. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

West Virginia: Clarksburg, Nov. 21-23. Chairman, Dr. S. L. Jepson, Capitol Bldg., Charleston.

REPORT OF THE THIRD EXAMINATION OF THE NATIONAL BOARD OF MEDICAL EXAMINERS

The third examination of the National Board of Medical Examiners was held in Chicago, Oct. 10-18, 1917. The subjects of the examination and the relative value of each were: anatomy, 100; physiology, 75; chemistry, 75; pathology, 50; materia medica, pharmacology and therapeutics, 75; medicine, 200; surgery, 200; obstetrics and gynecology, 100; hygiene and sanitation, 50, and medical jurisprudence, 25. A percentage of 75 was required to pass. Falling to 65 per cent. in two subjects, or below 50 in one subject constituted failure. Of the sixty-five who applied, sixty-two were found to have the essential preliminary and medical qualifications, and twenty-nine of these appeared for the examination. Of these twenty-two passed, six failed, and one for good reasons had to withdraw before completing the examinations. The results for the candidates examined were as follows:*

PASSED

Names of Candidates and Colleges	Year of Graduation
Robert W. Keeton, Northwestern Univ. Med. School	1916
Gordon E. Hein, Northwestern Univ. Med. School	1915

EXAMINATIONS AND TIME ALLOWED

Subject	Kind of Examination	
	Written	Other, and Remarks
Anatomy	3 hours	Oral with prepared Spec. 20 min. for each candidate
Chemistry	3 hours	Two hours laboratory in physiologic chemistry
Physiology	3 hours	Laboratory 2 hours
Pathology	3 hours	Laboratory exam. 20 min. each cand.
Bacteriology	2 hours	Laboratory 2 hours
Materia medica, pharmacology and therapeutics	3 hours	Laboratory 2 hours
Medicine	3 hours	Clinical lab. ½ hour each cand.; clin. med. 3 hours
Surgery	3 hours	Lab. op. surg. and applied anatomy, 2 hours; clin. exam., 3 hours
Eye, ear, nose and throat	....	Clinical exam., 20 min. each candidate
Dermatology	....	Clinical exam., 20 min. each candidate
Obstetrics and gynecology	3 hours	Oral exam. of 10 min. for each cand.
Hygiene	2 hours	
Medical jurisprudence	2 hours	

The examination consisted of written, oral, laboratory and clinical tests. The questions asked were as follows:

ANATOMY

Written Examination.—1. Describe the elbow joint with overlying structures and muscular attachments in immediate vicinity. 2. Name cavities of heart and describe the valves. 3. Define synarthrosis, amphiarthrosis, diarthrosis. Example of each. 4. Through what arteries is collateral circulation established after ligation of common carotid? 5. Origin, insertion, action and nerve supply of (*a*) triceps extensor cubiti; (*b*) serratus magnus; (*c*) pectoralis minor; (*d*) biceps femoris. 6. Describe the lacrimal apparatus.

Oral Examination.—Each candidate was examined orally for twenty minutes during the course of the written examination.

Gross Anatomy.—For this purpose the skeleton, prepared museum preparations, and fresh dissections were used.

Histology.—Identification of specimens under the microscope, (1) skin epithelium, (2) liver, (3) cartilage, (4) small intestine, (5) spinal cord.

PHYSIOLOGY

Written Examination.—1. Describe the methods by which may be determined the events of the cardiac cycle in the right and left sides of the heart, respectively, in man. Detail the results. 2. (*a*) What is the normal stimulus of the respiratory nerve center? (*b*) What is meant by the "buffer" action of the blood salts and what is its use? (*c*) What condition supervenes when the "buffer" action is inadequate? 3. (*a*) What relation has the "pulse pressure" in an artery to the volume of blood passing through it? (*b*) What are the factors determining pulse pressure? 4. Give evidence as to the functions of the thyroid gland. 5. Describe the origin and function of secretin. 6. Give the various functions of the sympathetic nerve. 7. Describe the stages of protein digestion. 8. Give the qualitative and quantitative essentials for the diet of a working man.

Practical Examination.—Each candidate was required to make 4 or 5 tests, as time permitted, of the following: Demonstrate the circulation in the web, mesentery, tongue or lung of a curarized frog. Differentiate the various vessels and point out the specific character of blood flow in them. 2. On a minor arterial schema eject by an intermittent pump water through (*a*) a rigid tube without peripheral resistance; (*b*) a rigid tube with peripheral resistance; (*c*) through an elastic tube without peripheral resistance; (*d*) through an elastic tube with peripheral resistance. Describe the results and deduce from them an explanation of the fundamental features of the blood circulation. 3. With the polygraph demonstrate and describe the human jugular pulse with the carotid or radial pulse as a chronoscope. 4. Obtain by the auscultatory method the human blood pressures with the subject in the recumbent and in the standing positions. Discuss the results. 5. Compare the maximal blood pressures in the brachial artery when the arm is held at various levels. Explain results. 6. With the human subject in the supine position, obtain the maximal blood pressure in the brachial artery; now apply a sandbag to the abdomen and repeat. Explain the difference, if any. 7. Pith a frog or terrapin and demonstrate on it by faradic stimulation the inhibitory function of the vagus nerve. Apply to the heart a solution of atropin and repeat. 8. Draw carefully graphic tracings representing the following: (*a*) The radial pulse; indicate on it the various phases of the heart's activity. (*b*) The normal arterial blood pressure tracing in the dog as obtained with mercury manometer, and the effect on it of vagus inhibition of various degrees: Explain. (*c*) The arterial pressure tracing in a rabbit and the effect of stimulating the depressor nerve: Explain. (*d*) Tracings representing the "auricular" and the "ventricular" forms of the jugular pulse. 9. (*a*) On a revolving smoked cylinder obtain the curve of a single muscular contraction excited by an induction shock. (*b*) Obtain the summation of two contractions. (*c*) Obtain an incomplete and a complete tetanus. (*d*) Varying the strength of the current, obtain a series of contractions from minimal to maximal. 10. Demonstrate the action of curare on the transmission of the motor impulse in a frog's nerve. 11. Make a nerve-muscle preparation from a hind limb of a frog, preserving the sciatic nerve, and dividing it close to the cord, cutting away the thigh muscles, dividing the femur at its lower third and leaving intact the skin of the leg and foot. Suspend the preparation inverted by a clamp at the knee: The foot will be extended when the gastrocnemius muscle contracts. Introduce a galvanic current into the nerve for a few seconds. Note the period of contraction and the relative effects of ascending and descending currents. Make and break the current and describe the results. Dip the end of the nerve into a saturated solution of NaCl and describe the results. Pinch the nerve and note results. Tie a string tightly round the middle of the nerve and note the effects of pinching on either side of the ligature. 12. (*a*) In a frog in which the brain has been destroyed, note the powers which have been lost and preserved. (*b*) Suspend the animal by the lower jaw and describe the reflex obtained by mechanical and chemical stimulation. (*c*) Inject under the skin of the back 1 drop of a 1 per cent. solution of strychnin: Note the changed response to stimulation; note the effect of destroying the spinal cord: Explain results. 13. (*a*) With the materials provided, test the reaction of saliva. (*b*) By means of the reagents provided, trace the changes induced in starch paste by digesting it with saliva. (*c*) Note the effect of cooling, of boiling the saliva. 14. Pour a little defibrinated blood into each of the four test tubes: Keeping one for comparison, add to the second an equal volume of water and warm slightly; to the third add a few drops of ether or chloroform and shake; to the fourth add a little bile and shake. Note and explain the conversion into "laky blood." 15. Arrange the spectroscope and obtain a series of absorption spectra of hemoglobin with various dilutions of laky blood. Describe. Obtain the spectrum of reduced hemoglobin with Stokes' fluid, and then reoxidize. Prepare carbon monoxid, hemoglobin and compare its spectrum with that of oxyhemoglobin.

PHYSIOLOGIC CHEMISTRY

Written Examination.—1. What is an amino acid and how many and what amino acids are found in the protein molecule? 2. Give the characteristic color tests for proteins and the significance from a chemical standpoint of each test. 3. Define a purin body and tell what purin substances are formed in the animal body, what relation they have to one another, and in what form each is eliminated. 4. Give the steps in the formation of urea, uric acid and hippuric acid in the body, and the significance of an excess or a deficiency of each of these substances in the urine. 5. Discuss in detail the coloring matters of the blood and the urine, giving the formation and function of these coloring matters and the significance of their presence in excess in the urine.

Laboratory Examination.—Candidates divided into two groups. Each group allowed two hours. Questions asked: 1. Make a quantitative estimation of the sugar in a sample of urine. Determine quantitatively the amount of glucose. 2. Estimate the amount of free hydrochloric acid in a sample of gastric content. 3. Make and report on the chemical and microscopic examination of a sample of urine. 4. Make and report on the examination of a sample of gastric content. 5. Determine the presence or absence of albumin reducing sugar. 6. Make and report on the chemical and microscopic examination of a sample of urine.

MATERIA MEDICA AND THERAPEUTICS

Written Examination.—Answer the first six questions; of the remaining six choose four: 1. (*a*) Give the source and physical properties of strychnin. (*b*) Describe the action of strychnin on the spinal cord. 2. (*a*) Describe two therapeutic uses of atropin, and state the proper dose to be given in each instance. (*b*) Describe two therapeutic uses of caffein, and state the proper dose to be given in each instance. 3. (*a*) Describe the source and physical properties of morphin. (*b*) Explain the analgesic action of morphin. (*c*) Explain the constipating effect of opium. 4. (*a*) What are the different stages of ether anesthesia? (*b*) Describe the stage of surgical anesthesia. (*c*) Describe the effect of hydrated chloral on the central nervous system, and give the principal therapeutic uses. 5. (*a*) Describe the pharmacologic action of digitalis on the heart muscle. (*b*) In which forms of cardiac disturbance does digitalis exert its best therapeutic effect? 6. What are the indications for the use of mercury in syphilis? 7. (*a*) Discuss fully the administration of quinin in malaria. (*b*) Write a prescription containing quinin, with full directions to the patient. 8. (*a*) Give the source of salicylic acid. (*b*) Describe the effects of large doses of the salicylates. (*c*) Write a prescription containing sodium salicylate, with full directions to the patient. 9. Describe the pharmacologic action and therapeutic use of epinephrin. 10. Name two dissimilar drugs classed as circulatory depressants, and state in what conditions you would use each. 11. Name two evacuants acting mainly on (*a*) small intestine; (*b*) large intestine; (*c*) rectum. (*d*) Define a cholagogue, and give one example. 12. (a) Name three preparations of iron used in medicine. (b) Discuss the relative value of iron and arsenic in anemia.

Practical Examination—Individual Laboratory Tests—One Hour.—The candidate is supplied with two frogs and two unknown test solutions. Inject 1 c.c. of the drug solution furnished into the abdominal lymph sac of the frog. Observe the effects and make a careful protocol and record of the changes in the (a) skin; (b) pupils; (c) reflexes; (d) general condition. Discuss the results, and give opinion as to the drug used.

Demonstration Test—One Hour.—A dog is prepared as follows: Anesthetized with ether, trachea exposed and severed, after which tracheal cannula is inserted and connected with ether bottle, artificial respiration being continued. The carotid artery is exposed and artificial cannula inserted, connected with manometer. A cannula has been inserted into Wharton's duct, and the chorda tympani and vagus nerve isolated, doubly ligated and cut. The right femoral vein is exposed and cannula inserted. Various drug solutions (marked A. B. C., etc.) will be introduced into the animal and the candidate is required to record his observation as to the effect on blood pressure, heart rate, respiration (rate and depth), salivary flow and size of pupil, and to interpret the same as indicated in each instance. 1. Note the effect of stimulation of the peripheral chorda tympani, and of the central and peripheral ends of the vagus. 2. Note the effect of the injection of 2 c.c. of drug solution A. 3. Repeat test No. 1. 4. Note the effect of the injection of 2 c.c. of drug solution B. 5. Repeat test No. 1. 6. Note the effect of the injection of 2 c.c. of drug solution C. 7. Repeat test No. 1. 8. Note the effect of a second injection of drug solution A. Diagnose the drug used in each instance and state the reasons.

BACTERIOLOGY, MEDICAL ZOOLOGY AND IMMUNITY

Written Examination.—1. (a) What are the most important points differentiating streptococci from pneumococci? (b) What are our present views as to types of pneumococci, and what bearing has this on the success of serum treatment of pneumonia? 2. (a) What are the general characteristics of *B. dysenteriae*, and how do we separate Shiga strains from Flexner ones? (b) Name the anaerobic and aerobic spore bearers of pathogenic importance in man. 3. (a) Name the various organisms which may cause meningitis. (b) What are the laboratory methods of diagnosis of a tuberculous meningitis, and what are the characteristics of the spinal fluid of such a case? 4. (a) How does an antitoxic serum differ from an antimicrobic one, and give two or more examples of each? (b) What is the difference between active and passive immunity. 5. (a) What are the laboratory methods for the diagnosis of a hookworm infection, and outline the life history of the parasite? (b) How do the segments and head of *Dibothriocephalus latus* differ from those of *Taenia saginata?*

Laboratory Examination—Two Hours.—Isolation and description of plate cultures prepared from discharge of the throat. Given several animal parasites for identification. Given several stained preparations for identification of special micro-organisms.

PATHOLOGY

Written Examination.—Answer five of the following questions: 1. Discuss post-traumatic embolism. 2. Contrast in parallel columns the distinguishing characteristics, gross and microscopic, of benign and malignant tumors of the breast. 3. Contrast in parallel columns the distinguishing characteristics, gross and microscopic, of the lesions in internal organs, of syphilis and tuberculosis. 4. Discuss the pathology of chronic interstitial hepatitis. 5. State briefly the pathologic conditions which may be present ten hours after the receipt of a nonfatal perforating gunshot wound of the abdomen. 6. An unknown middle-aged man has died six hours after having been found on the street, apparently in a drunken stupor: Give the general necropsy technic and the probable essential findings. 7. A man 48 years of age has died two years after the onset of typical pernicious anemia: Tabulate the gross and microscopic changes probably present in the several affected organs.

Laboratory Examination.—During the course of the written examination each candidate was given gross specimens and microscopic sections chosen from the following: Gross: Pulmonary tuberculosis; arteriosclerosis; infarct of spleen; carcinoma of breast; hepatic cirrhosis; typhoid ulcer of bowel. Microscopic: Glomerular nephritis; osteosarcoma; uterine polyp; leukoplakia; broncho-pneumonia.

MEDICAL JURISPRUDENCE

Written Examination.—1. (a) Define lunacy as legally recognized. (b) Name and briefly describe the varieties of insanity usually recognized. (c) What do you understand by "interdiction"? 2. (a) Define the medicolegal importance of feigned diseases. (b) Give three (3) examples of feigned diseases and indicate the method by which each may be discovered or confounded. 3. (a) Name one irritant poison, and give the symptoms or evidences found. (b) Give the mode of determining that death was due to such poison, including the postmortem findings. 4. (a) What is the difference between a "material" and an "expert" witness? (b) Give an example of a hypothetic question. 5. (a) What is the function of a coroner? (b) Give brief outline of the procedure to be followed in examining a body supposedly dead of asphyxiation by illuminating gas.

HYGIENE

Written Examination.—Give the routes of entry and exit of the casual organism in each of the following diseases: mumps, syphilis, dysentery, cerebrospinal meningitis, malaria. 2. What rôle does environment play in the spread of disease? 3. Discuss the advantages and disadvantages, from the hygienic point of view, of milk as a food. 4. Outline the steps in the eradication of an epidemic of bubonic plague. 5. What are the public health duties of a physician? 6. Discuss the biologic transmission of disease, and name the diseases so spread.

MEDICINE

Written Examination.—Answer ten of the following questions: 1. (a) Discuss the etiology of aortic insufficiency as it pertains to childhood, the adult, and the patient past 50 years of age. (b) Describe the murmur and vascular phenomena characteristic of aortic insufficiency. (c) What is understood by the incomplete types of angina pectoris? 2. Give the physical and other clinical signs required as a basis for a definite or probable diagnosis of pulmonary tuberculosis in the absence of the demonstration of tubercle bacilli in the sputum. 3. (a) Discuss the diagnostic signs of acute appendicitis and the indications for surgical treatment. (b) Give the diagnostic symptoms of chronic disease of the appendix. 4. (a) Discuss the clinical significance of nucleated red cells in blood smears (properly stained). (b) Define splenic anemia, and discuss its relation to diseases of the blood. 5. (a) Describe the urinary findings in chronic nephritis. (b) Discuss the causes of death in chronic nephritis. 6. (a) Discuss briefly the principles which govern the diet treatment in diabetes mellitus. (b) What are the criteria of improvement in this condition? 7. Outline in parallel columns the differential diagnostic signs of epilepsy and hystero-epilepsy. 8. In the case of a man 48 years of age with a right motor hemiplegia which came on suddenly following a short period of unconsciousness: (a) Discuss the several causes of this condition. (b) Outline the characteristic symptoms of the above. (c) Discuss the prognosis. 9. In the case of a child 6 months of age affected with summer diarrhea, give the method of arriving at a diagnosis, and outline a plan of treatment for the condition. 10. Given a case of a girl 8 years of age who is suddenly taken ill with vomiting, headache and a moderate fever: a laxative is given, but the fever continues with an increase in the headache and vomiting. Twenty-four hours later a thorough action of the bowels is obtained, but the temperature is still 102.6 F., pulse 112, respiration 24. The physical signs at this time are negative with the exception of some rigidity of the neck. State how you would investigate further, and give the plan of treatment according to the results obtained. 11. (a) Discuss the etiology of amebic dysentery. (b) Outline a plan of treatment for this condition. 12. Describe the characteristic symptoms of plague.

Laboratory Examination—One Hour.—1. Specimen of urine for chemical and microscopic examination, the candidate being given one of the following specimens: (a) With albumin and casts; (b) with sugar and diacetic acid; (c) with large amount of pus. 2. Examination of slides representing the following: Plasmodium malariae, leukemia, and pernicious anemia.

A written report on each specimen was required, and a brief oral examination on the clinical condition represented by the specimen.

Clinical Examination.—This examination was held in laboratories and wards of Cook County and Presbyterian hospitals.

Bedside Examination—Two Hours.—To each candidate was assigned a patient referred to as a *long case,* and given one hour and twenty minutes for the examination of the same. A written clinical history was required, which included the physical examination, and he was expected further to ask for the laboratory tests, with other special findings required by the nature of the disease condition. During twenty minutes of the time allowed, he was examined orally on the clinical history and diagnostic conclusions.

The candidate was assigned to a second patient referred to as a *short case,* where the physical examination was made before the examiner, and he was examined in regard to the findings and the disease condition concerned. For a period of ten to twenty minutes the candidate was further examined by the examiner in neurology in connection with patients presenting special neurologic conditions.

SURGERY

Written Examination.—Answer five of the following questions: 1. Give symptoms, prognosis and treatment of abscess of the brain. 2. Give diagnosis and differential diagnosis of carcinoma of the lip. 3. Give diagnosis, differential diagnosis and treatment of chronic cystic mastitis. 4. Give diagnosis, differential diagnosis and treatment of strangulated inguinal hernia. 5. Give diagnosis, prognosis and treatment of fracture of upper third of femur. 6. Give diagnosis, differential diagnosis and treatment of stone in the bladder.

Laboratory Examination in Operative Surgery and Applied Anatomy: Candidates were examined in two groups; two hours for each group. (a) *Operative test:* one of the following operations on a dog: 1. Trephine; 2. tracheotomy; 3. thoracotomy; 4. nephrectomy; 5. gastrostomy; 6. tendon suture; 7. nerve suture. (b) *Applied Anatomy:* Examination on living models. 1. Boundaries of anticubital fossa and relations of contents. 2. Describe the triangles of the neck and their contents. 3. Position and relation of structures at ankle joint. 4. Demonstrate Nelaton's line and Bryant's triangle. 5. Course and distribution of ulnar and external popliteal nerve.

Clinical Examination.—This was held in the wards at Presbyterian and Cook County Hospitals, two hours being allowed for each candidate. During one hour a long case was examined, and a written history prepared, after which a quiz was given of twenty minutes. Each candidate was also given two short cases which he could examine for fifteen minutes and then stand an examination of five minutes on each case.

Each candidate was examined thirty minutes on appropriate cases by the examiner in eye, ear, nose and throat diseases, and the same length of time by the examiner in dermatology.

OBSTETRICS AND GYNECOLOGY

Written Examination.—1. Describe briefly the changes that take place in the fecundated ovum up to the time that segmentation is complete. 2. Discuss pernicious vomiting in pregnancy. (a) Etiology; (b) Symptoms, including urinary findings; (c) Treatment. 3. Describe the clinical history, mechanism of labor and the treatment of a face presentation, left mento-anterior position. 4. Discuss the pathogenesis, symptoms and differential diagnosis of acute pyelitis complicating pregnancy. 5. Bacteriology, symptoms and treatment of puerperal sepsis. 6. Causes, ordinary complications and treatment of procidentia uteri. 7. Causes, symptoms and treatment of chronic en [illegible] Causes, symptoms and treatment of vesicovaginal fistula [illegible] diagnosis and treatment of purulent pelvic inflammation. 10. Diagnosis, prognosis and treatment of coexisting uterine fibroids and pregnancy.

Oral Examination.—During the course of the written examination each candidate was examined orally for ten minutes in clinical obstetrics.

Italian Colony for Malarial Children.—Five years ago a society was founded at Rome to care for children with malaria, and a sanatorium was equipped for them at Cosenza. The children are from the families coming to work during the season in the salt marshes. The pavilions sheltered twenty-five the first year and up to seventy-seven in 1913. The number since has somewhat declined. The children live out of doors practically all the time, and have regular school and other advantages. The sanatorium is not endowed but is supported by voluntary gifts. Its official title is the Colonia silana per bambini malarici, and the headquarters are Piazza Nicosa, Rome.

Book Notices

The Treatment of Infected Wounds. By A. Carrel and G. Dehelly. Translation by Herbert Child. With Introduction by Sir Anthony A. Bowlby, K.C.M.G., K.C.V.O., F.R.C.S., Surgeon General, Army Medical Service. Cloth. Price, $2. Pp. 238, with 97 illustrations. New York: Paul B. Hoeber, 1917.

Shortly after the outbreak of the war, Alexis Carrel, M.D., of the Rockefeller Institute, in collaboration with H. D. Dakin, Ph.D., of the Herter Laboratories, New York, seeking to discover the best means of treating war-wound infections, adopted the "*chemiotherapeutic*" method. To be successful, it was necessary, according to their views, to choose (1) a suitable antiseptic, which, in degree of concentration used and in length of time it must be applied, would be fatal to microbes but would "not produce obvious damage to the tissue," and (2) a proper surgical technic for the antiseptic treatment of the septic wounds. Carrel and Dehelly have told the story of the evolution and practice of this Carrel-Dakin method in this book, and it has been ably translated from the French by Herbert Child.

Unfortunately the chemical phase of the treatment has received far more attention than the surgical phase, owing, in part, to the needless advertising of antiseptics under nonscientific names. For the past two years, medical literature has been flooded with accounts and descriptions of Dakin's fluid, Dakin's fluid modified, Dakin's new antiseptic (Chloramin-T), Dakin's newest antiseptic (Dichloramin-T) and Dakin's water sterilizer (Halazone), etc. Yet in all these "discoveries" the potent agent has always been active chlorin (positively charged chlorin $[Cl^+]$), the same substance with which the medical profession has had well tried experience when employing calcium hypochlorite (bleaching powder) and the much abused solution of chlorinated soda (Labarraque's solution). True, Dakin has introduced some more adaptable forms for utilizing the available (oxidizing) chlorin; but they are not free from objections, nor do they seem to deserve the dignity that has been accorded them. Carrel and Dehelly apparently believe that the modified Dakin's solution ("neutral solution of chlorinated soda, N. N. R.") is the agent *ad perfectum.* The details of making this solution are given in full—essentially the treatment of a solution of assayed calcium hypochlorite with calculated amounts of sodium carbonate and bicarbonate, and dilution of the resultant liquid until it has a strength of from 0.45 to 0.50 per cent. sodium hypochlorite —no more, no less. The authors uphold Dakin's claim that this solution is neutral, is isotonic with the blood, has a high bactericidal power, is very slightly toxic, that "tissues provided with a normal circulation resist perfectly the action of Dakin's solution under the conditions of our experiments," etc. In the introduction the authors, in criticizing other work, state that "proceedings of learned societies are laden with reports based for the greater part on experiments and observations, incomplete, vitiated by faulty methods." We therefore expected this book to be scientifically reliable, but our anticipations have in many instances met disappointment. The terms used, such as "chloride of lime," are archaic, and much analytic evidence is lacking. The method of assay for the available chlorin in calcium hypochlorite directs that hydrochloric acid may be employed. This will give high results because of presence of chlorate; hence it is important that acetic acid and not hydrochloric acid be used. After the solution has been prepared, Dakin devised a method of testing its "neutrality" by throwing some powdered phenolphthalein on the surface of the solution; absence of a red color, he states, shows that it is not alkaline. It is, indeed, surprising that phenolphthalein should thus be used when every student in elementary analysis is taught that it is not reliable in such conditions. Dakin's solution is *not* neutral, but is alkaline, and should be alkaline when prepared in the manner described. If to some of Dakin's solution alkali be added, and the solution then tested by phenolphthalein, it will still give the "neutral" reaction. Just what limit of alkalinity the test indicates in practice awaits to be seen. The statement is also made in this book, and considerable stress has been laid on this point by various writers, that Dakin's solution "is isotonic to blood serum." However, McClendon has recently shown that, if the directions are followed, Dakin's solution is quite hypertonic. It may be that in this connection Dakin has a point in common with the adversary of chemical antiseptics, Sir Almroth Wright. In a comparison of the superiority of Dakin's solution over solution of chlorinated soda (Labarraque's solution), no data are given as to the source or composition of the latter. After all that has been written, it is possible that again we shall witness the completion of the cycle, with Labarraque's solution (diluted) as the beginning and the end, while some such salt as sodium bicarbonate will be added for hypertonicity.

Technical surgery in the war zone has had an indefatigable worker in Alexis Carrel. That he has done wonderful work is becoming better recognized, although the credit for the work has been inadvertently hidden by the mystery of Dakin's solution. It is still debatable whether the success is due to the irrigation of the wounds by hypochlorite solutions, as he explains in this book, or to the careful study of the patient, the bactericidal control of the wound, and the constant irrigation, in other words, cleanliness—asepsis.

Despite the foregoing criticisms, the book is well worth reading by every physician interested in the treatment of wounds. The reader should consider it in a conservative frame of mind, and not allow himself to be carried away by the enthusiasm that unfortunately attaches to the introduction of every new therapeutic procedure.

Medicolegal

Death from Fasting and Water Cure

(Feige vs. State (Ark.), 194 S. W. R. 865.)

The Supreme Court of Arkansas reverses for error in the trial a conviction of defendant Feige of the crime of manslaughter, and remands the case for a new trial. The court says that one Stratton, who had been stricken with paralysis, employed the defendant to treat the disease according to a fasting and water cure which was being practiced by the latter, which required the patient to abstain totally from the use of foods, and to drink all the water possible. The defendant took Stratton through a thirty-five day fast. During the last seventy-five hours of the fast, Stratton was seized with a severe attack of hiccups, to relieve him from which the defendant placed a wide leather strap around his body and buckled it up as tight as he could draw it. Mrs. Stratton became alarmed; the defendant was discharged, and two physicians were employed. When they took charge of the patient he was in a semicoma; his pulse was weak, fast and intermittent. They gave him a hypodermic of sparteine and then treated him for hiccups and a weakened condition. He recovered from the hiccups, but never recovered from the weakened condition, and died at the expiration of five days. The evidence on the part of the state tended to show that the treatment prescribed and administered by the defendant to Stratton was irrational, unreasonable, unscientific, and the proximate cause of his death. The evidence on the part of the defendant in a measure tended to show that the fasting and water cure, as practiced by him, was rational, reasonable and scientific, and had wrought wonderful cures, and that it might have worked a cure on Stratton had he been permitted to continue the fast. The cause was submitted to the jury on the theory that one who practices medicine for a remuneration would be guilty of involuntary manslaughter if death resulted to the patient on account of gross ignorance or lack of skill in selecting and administering the remedy. The instruction embodying this idea correctly declared the law as applicable to the theory advanced by the state. None of the instructions given clearly presented the theory of the defendant. The evidence in the record warranted an instruction allowing for a mistake in judgment. The defendant was at least entitled to an instruction defining the difference between a fe[illegible] lack of knowledge and skill, on the one hand, and a [illegible]ke of judgment, on the other. In words, the jury should not have been left in a position to confuse a mistake of judgment with gross ignorance or lack of skill. The defendant asked, and was refused, the following instruction which correctly presented the law applicable to the theory advanced by him, and to which he was entitled on the whole record: "Involuntary manslaughter is the involuntary killing done without design, intention, or purpose of killing, but in the commission of some unlawful act, or in the improper performance of some lawful act. For a mere mistake of judgment in the selection and application of remedies resulting in the death of his patient, a physician is not criminally liable; and whether one who assumes to practice medicine is grossly ignorant of the art or the selection of remedies or their application, or inapplicable or rashly applied, are all questions to be determined by the evidence." It was also insisted that an error was committed because the prosecuting attorney referred to the fact that the defendant did not have a license to practice medicine. The trial court indicated that it was an improper argument, as that issue was not involved in the case. It is unnecessary for the supreme court to comment on it, as the prosecuting attorney will not likely repeat the statement on a new trial. There was no error in a refusal to permit the defendant to read excerpts to the jury from a book entitled "McFadden's Physical Culture."

Not Bound to Follow Patient and Be Liable for Care of Wound

(Miles vs. Harris, (Tex.), 194 S. W. R. 839.)

The Court of Civil Appeals of Texas affirms a judgment rendered in favor of the defendant, and denies the plaintiff a rehearing, in this action for alleged negligence in letting a gauze packing remain in the body of the plaintiff's wife, on whom the defendant performed an operation in the abdominal region. The court says the defendant's evidence was to the effect that he performed the operation in the usual way; that the insertion of the gauze pack was necessary; that several days after the operation he attempted to remove the gauze pack, but the removal created or again started a dangerous flow of blood, which, under such circumstances as shown by the testimony, made it necessary to desist; that the plaintiff removed his wife from the defendant's sanatorium without the defendant's consent, and over his objection, during his temporary absence. The defendant and the attendant physician and nurse all testified to this fact, and further that the plaintiff was then informed that the pack had not been removed, because of which, and because of the presence of fever, it would be dangerous to remove the patient. The evidence further seemed uncontradicted that the family physician knew the gauze had been placed in the wound, and that, on the return of the plaintiff's wife to her home, he suspected its presence, but relied wholly on the assurance of the plaintiff and his wife that it had been abstracted. That there was evidence in behalf of the plaintiff of contrary import on one or more of the submitted issues could not alter the conclusion. Such evidence merely presented a conflict, which it was the function of the jury to determine. Under such circumstances and under the findings of the jury, the court knows of no rule that made it the duty of the defendant to follow the patient and be further liable for the due care of her wound. Again, the court says that it would seem that about the only material issue necessary for submission was the issue of whether the defendant was guilty of negligence which directly and proximately caused the gauze pack to remain in the person of the plaintiff's wife longer than it should have remained therein. That the defendant may, as the plaintiff insisted, have failed to remove the gauze in time; may have permitted the abdominal wound to heal without its removal; may have failed to inform the plaintiff or his wife of its presence in the body of Mrs. Miles at and before her removal from the sanatorium; that the defendant may have failed to advise the family physician that the gauze had not been removed—all seemed to constitute circumstances merely from which to infer negligence which resulted in the gauze remaining in the person of Mrs. Miles longer than it should. They were not, as it seems to the court, issues of themselves, but constituted mere evidences of the main fact to be proved, and hence it was not necessary to submit them to the jury in the form of special issues. If the defendant was not guilty of negligence in permitting the gauze pack to remain in the person of Mrs. Miles, as the jury found, it could not be material in this case that she suffered from that cause, for in such case the defendant at least could not be legally bound to respond in damages.

Society Proceedings

Amer. Public Health Association, Washington, D. C., Dec. 4-7.
Southern Medical Association, Memphis, November 12-15.

INTERSTATE ASSOCIATION OF ANESTHETISTS

Meeting held at Toledo, Ohio, Oct. 9-11, 1917

The President, Dr. Isabella C. Herb, Chicago, in the Chair

Nitrous Oxid-Oxygen Anesthesia

Dr. Charles W. Moots, Toledo, Ohio: Any operation of modern surgery can be satisfactorily performed under gas-oxygen anesthesia alone, without even the adjunct of local infiltration with novocain. Team work involves complete cooperation of the entire surgical force during the preoperative, operative and postoperative periods. Accurate diagnosis, painstaking preparation, sedatives, alkalinization, a preliminary narcotic and cheerful environment suffice to bring the patient to the operating room in the best possible condition for operation and anesthesia. The extreme Trendelenburg posture is never permitted, and any other changes of position are gradually made. The velvet touch and thorough saturation with the anesthetic give sufficient relaxation for any abdominal work. Experience shows that nothing serious happens to a patient on the table without showing circulatory changes. Therefore my expert anesthetists keep me continually informed regarding systolic, diastolic and pulse pressure, along with the pulse rate and the respiratory rate and volume. The character of the respirations is of great importance, especially in hazardous risks.

Further Researches in Blood Changes Under Nitrous Oxid-Oxygen Anesthesia

Dr. Theodore D. Casto, Philadelphia: In a previous paper I reported that nitrous oxid-oxygen anesthesia in man gives rise to a decrease in the erythrocytes, and that thirty or forty minutes after anesthesia there is a tendency for the count of erythrocytes to return to the normal value determined prior to anesthesia. My present communication includes, besides cellular alterations, a consideration of the influence of nitrous oxid-oxygen anesthesia on the degree of *alkalinity of the blood*. Albino rats were used for experimental purposes. Marriott's method of determining the hydrogen ion concentration, to determine the alkaline reserve, was used. Anesthesia was continued from thirty to sixty minutes. After definite periods of anesthesia, the animals were killed by quick decapitation, and blood counts and hydrogen ion concentration tests made. In the blood counts of twenty-one animals, the erythrocytes showed a difference of 4.8 millions per cubic millimeter between the highest and the lowest counts. The erythrocytes were decreased after gas-oxygen anesthesia for from thirty to sixty minutes, the maximum decrease being 70 and the minimum 1 per cent., with an average of 25 per cent. Macrocytes and microcytes were present in a few cases, but no poikilocytes or nucleated cells. Reaction to staining was slightly diminished in the erythrocytes in a few animals. The leukocyte count revealed an increase in eight experiments and a decrease in twelve. A study of the different varieties of leukocytes, however, showed a marked tendency on the part of the polymorphonuclear lymphocytes to increase. Of the twenty animals studied, eighteen gave a decrease in polymorphonuclear *neutrophils*, varying from 1 to 75 per cent., and sixteen of the animals gave an increase in lymphocytes varying from 5 to 23 per cent. The transitional eosinophils showed no change of special interest. There was no constant change in the segmentation of the polymorphonuclear neutrophils.

Liquid Air and Electrolytic Oxygen for Anesthetic Purposes

Dr. C. C. McLean, Dayton, Ohio: The increasing demand for oxygen in medical work makes it imperative to secure a pure and cheap supply of oxygen. Commercial oxygen for the welding process is now produced by the atmospheric or electrolytic methods. Medicinal oxygen is produced chemically. Chemical oxygen must have its poisonous chlorin residue eliminated. In neither the liquid air nor electrolytic process is chlorin contamination a problem. The impurity in electrolytic oxygen is hydrogen, the impurity in liquid air oxygen is nitrogen, both inert gases, and so far as is known, harmless in the quantities in which they are found. Provided the commercial oxygen is prepared for medicinal purposes and stored in cylinders not previously contaminated by poisonous gases, it may be utilized without danger. The following standards of purity are recommended: The gas should be neutral to moist litmus paper, and when passed through an aqueous solution of silver nitrate it should produce no turbidity. Not more than an opalescence should be produced when 2 liters of the gas are passed slowly through an aqueous solution of barium hydroxid. When 5 liters of gas are passed slowly through an aqueous solution of sodium hydroxid, then over heated copper oxid and finally through an aqueous solution of barium hydroxid, no turbidity should be produced. The gas should contain at least 94 per cent. of oxygen on the dry basis, and should contain no liquids and no solids.

Lung Complications Following Operations Under Anesthesia

Dr. E. I. McKesson, Toledo, Ohio: In a compiled series of 39,438 operations under all forms of anesthesia, lung complications followed in 3.03 per cent. of the cases in which figures are available. There was a total mortality of 1.06 per cent. Of these lung complications, 48 per cent. were pneumonia; and of the pneumonia cases, 48 per cent. were fatal. In one of the series of cases, 70 per cent. of the lung complications occurred in the five winter months. In attempting to reduce the incidence of postoperative lung complications, it is essential to maintain the temperature of the operating room at 80 F., to use a thick, warm, comfortable mattress on the operating table; to avoid careless operating, and to prevent the patient from sweating. It is equally as important to institute prophylactic measures of oral hygiene previous to operation, and for the anesthetists to use such methods of narcosis and technic as maintain an open airway, preclude the hypersecretion of mucus, and obviate the inspiration of blood or septic material. After operation, patients should be returned to a warm bed, should be protected from drafts, and should be permitted their customary weight of underwear. Etherization should be avoided in all cases in which it is contraindicated. Tight binders should be eliminated, sufficient opiate should be given to relieve pain, and full breathing should be encouraged. The position of the patient in bed should be changed frequently during the first week.

Some Observations on the Causes of Postoperative Nephritis

Dr. Karl R. Ruddell, Indianapolis: These observations are the result of a critical study of about 500 cases to determine the relative importance of ether anesthesia and focal infection in the causation of postoperative nephritis. In the series, 59.3 per cent. examined before operation showed evidence of an existing nephritis; 5.6 per cent. showed albumin alone; 0.7 per cent. showed albumin and pus cells, and 17 per cent. showed albumin, pus cells and casts. In the postoperative urines, 64 per cent. gave evidence of kidney involvement, an increase of 4.7 per cent. The majority showing postoperative kidney disturbance, in which the preoperative urines were normal, proved to be simple cases of albuminuria which subsided in a few days. Postoperative nephritis, in my opinion, is produced by a combination of causes, among which are the existence of a kidney already crippled by infection; an increase in waste products to be eleminated, incident to operative trauma, and possibly the dissolution of lipoids; a decrease in the liquid output due to a diminution in the ingestion of liquids, and an increased loss of fluids through the skin, lungs and intestinal tract; a lessening of its eliminative power by a lowered blood pressure in the kidney itself; a lowering of the power of resistance of the body by loss of heat due to prolonged anesthesia and shock; and lastly, the filtering of bacteria and their toxins, thrown directly into the blood and lymph streams from focal areas of infection. Ether plays a very insignificant rôle in the production of postoperative nephritis.

Comparative Dangers and Availability of Nitrous Oxid-Oxygen Anesthesia

Dr. J. R. McCurdy, Pittsburgh: While the anesthetic statistics collected by A. H. Miller give nitrous oxid-oxygen anesthesia the lowest mortality, it is interesting to note that deaths under this anesthetic are becoming more frequent as it comes into more general use. These fatalities can almost invariably be traced to incompetent or inexperienced administrators, extrahazardous risks, or the pushing of the anesthetic beyond safe limitations to accommodate the demands of the operator for greater relaxation. In the hands of experts, nitrous oxid-oxygen anesthesia is establishing itself as the safest anesthetic. Its chief danger is asphyxia, and this untoward complication can be almost instantly corrected by the proper admixture of oxygen. Its effects on the respiratory system are minimal, and it can be used to advantage in the presence of all pulmonary complications. It does not lower body resistance or disturb metabolism, and its administration is singularly free from postoperative pulmonary complications. Even uncompensated heart lesions may be safely handled, and lengthy administrations do not show the cardiac collapse incident to ether depression following its initial stimulation. Of all anesthetics, it affects blood pressure the least, and contrary to the usual opinion, it is not contraindicated by preexisting hypertension.

3. **Study of Causes of Abortion.**—During the four and a half months of Royston's investigation 563 patients were examined. Among these 563 a history of abortion was elicited in 178. Of these, 164 were subjected to detailed study. The 164 patients selected had a grand total of [illegible] pregnancies 348 of which ended in abortion. Criminal abortion was the most common factor in the series. [illegible] women [illegible] to an induced labor. Many of these had th[illegible]ce repeated a number of times.

women had in all 220 pregnancies of which more than half, namely 118 (52.4 per cent.) resulted in abortion. Of these 118, 84 (71.1 per cent.) were frankly acknowledged to have been induced. Comparing the percentage of induced abortions with the abortions in his entire material, Royston arrived at the figure 23.8 per cent. Only twenty (39.2 per cent.) produced living children after having had abortions induced. Only 10 out of the 51 patients had normal genital organs; the remaining 41 were more or less permanently disabled. Among the 164 cases, 46 gave a positive Wassermann and 5 patients with definite histories gave negative reactions after having been treated. Three additional patients showed lesions of the disease, though with negative histories and negative Wassermann reactions. These latter three had taken no specific treatment and were possibly cases of latent syphilis. Excluding these three mentioned, 51 patients were undoubtedly syphilitic. Only 12 of the 51 patients with syphilis gave a history, or showed any lesions of the disease. This means that between one-fourth and one-third of Royston's entire material was syphilitic; it shows that 34 out of 46 (73.9 per cent.) had latent syphilis. Among 51 patients, there were 186 pregnancies, 115 (61.8 per cent.) of which ended in abortion. Before syphilitic infection occurred, 3.8 per cent. aborted as compared with 78 per cent. after infection. In cases in which 48.8 per cent. survivors were born before, only 5.2 per cent. survived after syphilitic infection. Abortions are caused by syphilis much more frequently than the medical public realizes. Royston suggests that any patient who gives a history of one or more previous abortions had best be considered a victim of syphilis until incontrovertible proof to the contrary is obtained. Any other general disease of the mother may produce an abortion provided it is severe enough to affect the fetus or the placenta through changes in the maternal circulation. Of such there were 40 among the 164.

5. **New Method of Extraperitoneal Cesarean Section.**—The procedure employed by Cherry is very similar to the Hirst method. The patient is prepared as for any abdominal section, incision in the median line is made from the symphysis to the umbilicus through skin, fat and fascia of the recti. The muscles are separated by blunt dissection exposing the transversalis fascia and peritoneum. At this stage the edges of the muscle are bluntly dissected off the peritoneum for a slight distance until the deep epigastric vessels are seen, which allows for freer play of the peritoneum. The peritoneum is opened vertically, and the cut edges of the parietal peritoneum are then sutured to the visceral peritoneum in such a manner that an oval area about 5 inches long and 3½ inches wide in the lower uterine segment is left exposed, care being taken to interrupt and tie this continuous suture at several points to prevent it acting as a purse string. This procedure shuts out the general peritoneal cavity. The thin lower uterine segment is then incised in the median line for 4½ inches and the blades of the obstetrical forceps are introduced to the sides of the fetal head, and the child extracted. The placenta and membranes are then delivered. One cubic centimeter of pituitary extract is given intramuscularly at this stage followed immediately by 30 minims of ergotol. The uterine wound is then closed by interrupted chromic gut sutures; a continuous seromuscular suture is made over this line of sutures and the sutured edges of parietal and visceral peritoneum are sutured together. The rest of the wound is closed in the usual manner without drainage.

18. **Serum Therapy in Acute Lobar Pneumonia.**—Eleven cases are reported on by Bloomfield. They were all instances of frank lobar pneumonia, in which the Type I pneumococcus was demonstrated in the sputum or blood. Nearly all the patients came in with the disease well advanced—thus presenting conditions unfavorable to treatment. In addition to the serum, hydrotherapy, digitalis, and symptomatic measures were employed. The pneumococcus was usually isolated from the sputum by mouse inoculation, and the type determined by agglutination with stock immune serums. The serum was warmed to body temperature and injected intravenously by gravity, at the rate of 2 to 4 c.c. a minute. A preliminary desensitizing dose of 1 to 5 c.c. was given subcutaneously or intravenously. Blood cultures were made before and after treatments, and samples of blood were drawn for the agglutination tests. In five of the cases pneumococci were present in the blood before treatment was begun. In four of these the blood promptly became sterile after the injection of the serum, although in one case there was a terminal sepsis after fourteen days. In another case the one injection reduced the colonies from 900 to 25 per cubic centimeter, but did not prevent death; one patient died without any reapparance of the organisms in the blood. In six cases no organisms were present on admission, and the blood remained sterile throughout. All these patients recovered. The serum is, therefore, clearly an effective agent in sterilizing the blood, and in preventing the development of septicemia. The agglutinins were studied in eight of the cases. There was a striking variation in the titer of various patients' serums even after injection of the same amount of serum. The titer of the patient's serum following therapy bore no constant relation to the outcome of the case. Therefore, it is not a guide to the efficacy of treatment. There was no striking change in the clinical course of the cases which could clearly be attributed to the serum. This series throws little light on the curative value of the serum.

19. **Types of Pneumococci Isolated from Acute Lobar Pneumonia.**—In all, 121 strains of pneumococci were isolated by Clough and the groups determined. The percentage incidence of Groups I (35.2), III (14.8) and IV (25.9) in the lobar pneumonias in adults corresponds very closely to figures obtained at the Rockefeller Institute in their pneumonias. The striking feature in this series is the relatively very low percentage of typical Group II pneumococci (5.5) and the correspondingly high percentage of atypical Group II strains (16.7). The small series (13) of lobar pneumonias in children showed a slightly lower incidence of Groups I (30.8) and III (0.0) with a correspondingly higher incidence of Groups IV (30.8) and Atypical II (23.1) as compared with the lobar pneumonias of adults. If, however, the empyemas in children are added to the pneumonias and the percentage of these sums calculated, the incidence of Groups I and II becomes slightly higher than in the pneumonias in adults. This discrepancy is explained in two ways. In the first place, only lung puncture material was used for the cultures in this series, while most of the cultures obtained by the other authors were from sputum. In the second place, all the cases in the series were lobar pneumonias, while other authors included bronchopneumonias with lobar pneumonias in their statistics. Of the atypical Group II pneumococci isolated from lobar pneumonias (23.1) in children and from empyemas (14.3) three out of the six belonged to Subgroup II B.

A Group I pneumococcus was isolated from one out of ten cases of bronchopneumonia. The other cases were due to Types III, IV and Atypical II in about equal percentages. An interesting case in which a Group I was isolated from an otitis media and from mouth sputum gave a history of a mild pneumonia following "grippe" nine months previously, and presumably had been a carrier throughout this period. The total mortality of the series was high (50 per cent.). In all of eight cases due to the pneumococcus mucosus the patients died. The mortality of the Group IV cases was relatively very high (57.2 per cent.). The explanation is probably the greater average age of the cases of this group (40.5 years), and the very high percentage of associated diseases in these cases (71.4 per cent.), as compared with 20.3 per cent., 33.3 per cent., and 25 per cent. in the fixed types. Marked alcoholism is included as an associated disease on account of the large part which it seems to play in the incidence and mortality of pneumonia. The same explanation is offered for the mortality of the pneumonias due to Atypical II strains (60 per cent.), which is higher than one would expect with organisms which are usually relatively avirulent. Several terminal pneumonias and one postoperative pneumonia were included in this study, all of which were due to Type IV or Atypical II organisms.

21. **Bacteremia in Lobar Pneumonia.**—Sutton and Sevier endeavored to determine the course of the sepsis in cases with positive blood cultures, to see whether this varied according to the type of infecting organism, and finally to determine the relation of the bacteremia to prognosis. Of the entire series of sixty-six cases only three patients died whose blood cultures were persistently negative. No patient recovered who had, at any time of the disease, over 5 colonies per cubic centimeter of blood, whether he received specific therapy or not, with the exception of one patient who had 20 colonies per cubic centimeter on admission, and a severe alcoholic delirium. This patient, however, received a serum within a few hours of admission, and subsequent doses until after his temperature had become normal. All the deaths excepting that of the patient showing a negative blood culture, occurred in the four months between December 8 and April 8, although sixteen cases occurred before or after this period. This is also the period within which all the positive cultures were obtained. Do the fixed types vary in virulence throughout the year, or does the severity of the initial exposure during the period of maximal changes in weather predispose to the type of pneumonia that runs its course with a septicemia? In general, the incidence of septicemia runs parallel with the mortality. If the cases with a transient sepsis, having only an occasional colony early in the disease, are omitted, the percentages of positive blood cultures and mortality are practically identical. As regards prognosis, the authors have found blood cultures the most valuable aid. Of the patients with persistently negative blood cultures 93 per cent. recovered without any complications. Of the patients with positive cultures, all with over 5 colonies per cubic centimeter at any period of the disease died, except one with 20 colonies on admission, who received serum therapy.

29. **Emanuel-Cutting Mastiche Test on Spinal Fluid.**—The authors tested the fluids from 268 patients. Of these, seventy-four fall into the general group of syphilis of the nervous system, the majority of the remainder being nonsyphilitic psychopaths and nonpsychopaths, with the addition of three cases of acute meningitis. In all cases the following tests were made: Wassermann test in blood and spinal fluid; albumin, globulin, cell count and colloidal gold tests, in spinal fluid. Smith and Lowrey are of the opinion that the mastiche test, as modified by Cutting, has a distinct place in the clinical laboratory. Because of the ease and accuracy of examination it may well be used to determine in which cases the more complicated gold test should be made. Their experience indicates that the test does not differentiate between syphilis and acute meningitis; hence the chances are that the reactions in tubercular meningitis and tumors will not be differential. It has a place in the examination of spinal fluids, especially where large numbers of spinal fluids are examined. In all cases showing clouding with mastiche, a gold reaction should be performed as a final check.

51 *Existence of Gastric Lipase. M. Hull and R. W. Keeton, Chicago.—p. 127.

43. **Pellagra Producing Diets.**—According to McCollum and Simmonds two practices make for safety in human nutrition in those districts where the water is low in sodium and calcium. These are, first, the consumption of milk as a regular article of diet, and second, the use of the leaves of plants as human food. Milk is always high in calcium and, as a rule, contains a far greater amount of sodium chlorid than do any of the seeds. The same is true of the leaves of plants. It is highly probable that meats do not make good the mineral deficiencies of a diet derived principally from seeds. The authors emphasize the importance of using milk as a regular constituent of the human diet and also the great benefit which would result from a more extensive use of the leaves of plants as a stable article of the diet. There is grave danger in deriving nearly the whole food supply from the seeds of plants.

44. **Uric Acid in Blood.**—Slemons and Bogert found that the uric acid content of the blood during uncomplicated pregnancy falls within the limits accepted as normal at other times (2 to 5 mg. per 100 c.c. of blood). Larger values were found in cases of syphilis, pyelitis and the toxemias of pregnancy. At the conclusion of labor higher values usually prevail in primiparous than in multiparous women. This may be explained by the longer duration and the more energetic character of the labor in the case of the first birth. In several cases an increased uric acid content of the blood after labor was demonstrated. Equivalent values for the uric acid in the blood of mother and fetus indicate that uric acid passes through the placenta by diffusion. As a rule, the uric

acid of the blood is notably increased in cases of eclampsia and also of nephritis during pregnancy; consequently, these clinical complications may not be distinguished by estimation of the blood uric acid.

45. **Lactic Acid in Urine.**—Maver maintains that while the method of Schneyer is of unquestionable value in indicating the excretion of substances belonging to a group capable of yielding carbon monoxid, it cannot be applied to the quantitative determination of lactic acid in the urine.

46. **Utilization of Carbohydrate on High and Low Cereal Diets.**—Experiments reported on by Zentmire and Fowler show that the utilization of total carbohydrates of a diet consisting largely of cereal is above 99 per cent. The carbohydrate is as completely utilized with one quantity as another of cereal in the diet, even when the cereal is taken in larger amounts than are found in the average dietary. Assuming that sucrose and lactose are completely digested and absorbed, the utilization of the cereal carbohydrate is still high (97.7 to 99.0 per cent.). Assuming that sucrose is completely utilized, the starch of the starch diets is utilized to the extent of over 98 per cent. Monotony and unpalatability of diet have little or no effect on the ultimate utilization.

48. **Nutritive Value of Soy Bean.**—An economic consideration of the yellow soy bean leads to the conclusion that it is one of the most valuable of the leguminous seeds. It contains a high percentage of a physiologically good protein, a considerable amount of energy yielding material in the form of fat and carbohydrate, and a fairly liberal supply of the fat-soluble food accessory, as well as of the water-soluble growth determinant. The animals fed rations containing 15.6 and 18.7 per cent. of protein obtained solely from the soy bean have grown normally and in the latter case have produced successive litters of young, which in turn have reproduced, is sufficient evidence that the protein of the soy bean fulfills all physiologic requirements. The protein of the soy bean appears to be quite as valuable as the casein of milk. In order to make the soy bean a more nearly complete food, suitable inorganic material, consisting principally of sodium chlorid and calcium compounds, needs to be added.

51. **Existence of Gastric Lipase.**—The occurrence of gastric lipase was studied by Hull and Keeton in pure juice obtained from dogs with Pawlow stomachs and those with pylorus ligated. The secretion was excited by gastrin bodies and food. It was found that the fasting and acid-free juice always contains an appreciable concentration of lipase. The lipase is quite sensitive to acid and alkali, being almost completely destroyed by a fifteen minute exposure to 0.2 per cent. hydrochloric acid. The enzyme may be recovered from the stomach showing low acid secretion by neutralizing the juice immediately; and from stomachs in high secretory activity, if the acid be reduced by the addition of protein, such as peptone. In a series of trials 1 c.c. of fasting juice gave a fat splitting of 28.2 per cent. by the Volhard method and 22.05 per cent. by the Stade modification. The concentration of the enzyme in the gastric juice is five or six times that in the succus entericus and the blood serum. The view that the lipase is a true gastric secretory product is discussed and favored. The probable practical importance of the lipase in stomach digestion is emphasized.

56. **Endameba Buccalis.**—The material for this present paper was collected by Nowlin from a single host and a single point of infection, an upper premolar tooth. Nowlin concludes from observations that *Endameba buccalis* absorbes its food mainly, taking in by osmosis the fluids of leukocytes or other mediums on which it rests, stores these colloidal substances in vacuoles, and by secretion of its own enzymes assimilates these as needed. This method of food getting by absorption would explain the shrinkage of gums where *Endameba buccalis* is present. There is abundant evidence that they draw supplies by applying themselves to the surface of tissues and by crowding between them.

76. **Care of Disabled Returned Soldiers.**—In addition to general medical and surgical hospitals, Bailey's plans include convalescent homes for those enfeebled rather than disabled, sanatorium for consumptives and colonies of various kinds at which outdoor work can be taken up little by little. Vocational training is an important part of the scheme, especially for those whose disability forces them to find a different occupation than the one they had before entering the army. This feature involves questions concerning the soldier's personality, and also has associated with it such perplexing questions as the rating of pensions, attitude of trade unions, state versus federal supervision, etc. The nervous casualties require a high degree of differentiation in their treatment.

The insane should be carefully segregated from those whose mental disturbances are susceptible of more prompt recovery; the hysterics should be kept by themselves, and special education centers will be found necessary for the care of the disorders of speech and hearing so frequent in this war. The final feature in Bailey's plan is the creation of federal and state boards of reemployment, which shall meet the returned soldier at all points of discharge and facilitate his return to self-support and independence in the civil community.

79. **Psychology and Military Activities.**—Yerkes suggests that psychologists can render service to the nation by discovering and indicating in practical ways the relations of human characteristics to special tasks.

81. **Nervous Conditions Arising in Present War.**—The large number of cases of mental disorders, functional and organic, makes necessary the presence of a physician trained to make thorough studies of and successfully treat mental patients. This requires a patience and skill obtained only through a thorough understanding of the conditions resulting from fatigue, worry, fright, shock, etc. In the organic cases, in which foreign bodies, such as shrapnel, have penetrated the nervous tissue, the roentgen ray has proved an invaluable asset in localization, for not infrequently, due to more extensive involvement resultant from hemorrhage and destruction, the neurologic symptoms do not correspond exactly with the site of the foreign body. For the more careful consideration of mental cases in the Base Hospitals, Auer says, huts should be assigned to a neuropsychiatric service, where the functional nervous and mental conditions can receive proper treatment in the way of complete rest, isolation, dietary measures, and such other treatment as may be required. The cases of organic injury to the nervous system should also be received in a special hut in the surgical division, where the surgeon and the neurologist can more competently care for the wounded and make a more thorough study of the findings.

82. **Mental Disease in Canadian Army.**—Of the total number of soldiers invalided to Canada, the proportion of nervous and mental cases has been fairly constant at 10 per cent., classified as follows: neurotic reactions, 58 per cent.; mental diseases and defect, 16 per cent.; head injuries, 14 per cent.; epilepsy and epileptoid, 8 per cent.; organic diseases of the central nervous system, 4 per cent. In the general policy of caring for the war neuroses, Farrar says, it has been demonstrated over and over again, that patients while under treatment should be shifted as little as possible from one institution to another. It is also as a rule, not well to have the patient in the vicinity of his home, and home visits are certainly contraindicated in the severer neuroses. The conscious will and purpose to get well are often difficult to establish and all opposing factors must be kept in mind.

138. **Surgical Treatment for Hay Fever.**—Miller says that there is a condition in all cases of hay fever of highly sen-

sitized parts of the mucous membrane supplied by the olfactory nerve. This is caused in all cases he has seen by a malformation of the nose. This malformation can either be an enlarged superior turbinate, a deviated septum or a very close nose. At any rate, there is a pressure between the superior turbinates and the septum, causing a highly inflamed and sensitized condition of the mucous membrane at the ramifications of the olfactory nerve. These are the patients who have hay fever. Miller relieves this pressure by removing the superior turbinate or by the proper application of trichloracetic acid.

1. **Hysterical Deafness in Soldiers.**—Hurst and Peters are convinced from their experience that absolute deafness associated with normal vestibular reactions should be regarded as hysterical, and when simple encouragement fails, as will generally be the case if the patient is not also dumb, an "operation" should be performed after the patient has been made to feel quite confident that it will restore his hearing. This "operation" is described as having been applied in two cases of absolute hysterical deafness without mutism, and in one of them mutism was originally present, but spontaneous recovery had occurred some months earlier in which all treatment had failed. The first patient was given enough ether to make him excited, and two small cuts were then made behind his ear; a hammer was banged on a sheet of iron during the "operation," and the moment after the incision had been made the patient jumped off the table with his hearing restored. The other patient was unwilling at first to undergo an operation, but finally consented, as he was naturally impressed by the recovery of the first patient, who was in the same ward and had been deaf for a much longer period. The same "operation" was performed and complete recovery occurred in exactly the same way.

2. **Reactions to Human and Bovine Tuberculin.**—Gauvain applied the Pirquet test to eighty cases of tuberculous bones or joints. In order to avoid any risk of unconscious bias he made the inoculations and recorded their results without knowledge of bacteriologic reports as to the type of bacillus found. The tuberculins employed were Koch's "old tuberculin," prepared from the "human" type of bacilli, and his tuberculin prepared in the identical way from bacilli of bovine origin. The tuberculins were applied to suitable skin scarifications in dilutions of 1/64, 1/16, 1/4, and in full strength, each in approximately equal bulk and controlled by inoculation of a scarification with the same quantity of sterile normal saline solution. The final result of Gauvain's investigation may be stated briefly as follows: 1. Local reactions to inoculations of both human and bovine tuberculin were invariably present in all patients from whose pus tubercle bacilli had been isolated. 2. Though reactions were invariably present, the degree of reaction varied within wide limits. 3. Weakly and cachectic patients usually reacted feebly, quite irrespective of differences in the severity of their local lesions. 4. Strong and vigorous patients exhibited wide differences in the degree of their reactions, irrespective of differences in the extent or the severity of their local lesions. 5. The quantitative Pirquet test was found to be of value in forming an estimate of the severity of the infection, and was of little prognostic value. 6. It was impossible to differentiate the type of tubercle bacillus with which the patient was attacked by the nature of the reaction to the tuberculin employed.

3. **New Dietetic Treatment of Diabetes.**—Cammidge points out that at present our only reliable means of combating the disease is management of the diet, but in order to obtain the best results and actually halt the diabetic process it is necessary that it should be carried out with knowledge and as nice discrimination as the selection and prescription of a drug. Time and care devoted to the chemical aspect of each case render the task easier, and would prevent the empirical employment of one routine method, so saving many patients from unnecessary hardships and inconveniences. It is not enough to consider only the glycosuria, or even the end-products of metabolism in the urine, the information to be obtained from analysis of the blood and feces should also be taken into account, and Cammidge thinks that the time is coming, and will come shortly, when a physician who attempts to treat a case of diabetes guided only by examination of the urine for sugar will be held as guilty of negligence as the present-day surgeon would be who failed to employ roentgenography when treating an injury of the bones or joints.

4. **Meningococcus Carriers Treated with Antiseptics.**—Owing to the measures adopted in the British Navy to limit the spread of cerebrospinal fever a large number of carriers were detected in the Portsmouth depot and isolated in a special camp. It then became necessary to attempt to sterilize the throats of these men, and, although from analogy with other diseases the local application of antiseptics appeared likely to be unprofitable, it was thought desirable to give these a trial. If the antiseptic did not destroy the cocci in the throat, it was possible that it might prevent the cross infection from one man to another. The antiseptics most thoroughly tested were chloramin-T and acriflavine. Other antiseptics were boric acid, phenol, magnesium hypochlorite, aqueous solution of formaldehyd gas, potassium permanganate, guaiacol and several others. In addition to these, Fildes and Wallis administered to a few men a placebo in the form of tablets of formaldehyd solution. Chloramin-T was applied in two different ways: (*a*) In an inhaling chamber: A 5 per cent. solution of chloramin-T was used in the reservoir of the nebulizer; this strength was found to give as powerful an atmosphere of chlorin as was pleasant. The men remained in the chamber for about fifteen minutes per diem. (*b*) In a nasopharyngeal spray: The chloramin-T (2 per cent.) thus came copiously into contact with the whole nasopharynx and often dripped from the anterior nares. This treatment was applied once a day. Acriflavine in a strength of 1 in 500 in salt solution, was applied daily with the authors' nasopharyngeal spray. The other antiseptics mentioned were all applied with a nasal spray until the drug could be felt in the nasopharynx. The strength of boric acid was 1 dram to the pint, of phenol 1 in 200, of liquor formaldehyd 1 in 200, and of potassium permanganate 1 in 1,000. Looking at the results as a whole, Fildes and Wallis conclude that one third of the men recover spontaneously, and that none of the methods of treatment tested has any conspicuous merit, nor has one any obvious advantage over another. This result is what might be expected from analogy with work on diphtheria carriers.

5. **Closure of War Wounds in Home Hospitals.**—The method which experience has led Phillips to adopt includes something of the bismuth iodoform petrolatum paste method along with the sodium hypochlorite treatment. Where pus is pocketing in the track of a through-and-through wound, or beneath or between two adjacent muscles, or where loose bone fragments or other devitalized or foreign bodies are present, an anesthetic must be given and the wound cleansed and laid freely open. The skin incision whenever possible should extend the whole length of the wound. The ideal Carrel wound is a basin which can easily be kept full to the brim with the hypochlorite solution. Every third or fourth day a platinum loopful of the discharge is taken from the wound surface wherever it looks least healthy and examined bacteriologically. Phillips makes it a rule not to attempt to close a wound until two reports of an average of less than three organisms per field have been returned.

Wound Closure: The skin around the surgically clean wound is cleansed, the edges of the wound are trimmed, the granulations are thoroughly curetted, the skin edges are undercut. Any definitely bleeding vessels are tied (oozing does not matter), the whole wound area is swabbed with methylated spirit and a little bismuth iodoform petrolatum paste is scrubbed into the raw surface with the gloved fingers. Wherever possible any raw muscle surface is closed by bringing together the edges of the deep fascia (exposed by the under cutting) with a running stitch of stout catgut. Thick silk sutures (No. 5 pedicle silk boiled and soaked for forty-eight hours in tincture of iodin) are passed through the skin and the deep layers of the wound at intervals of about ¾ inch and tied tightly so that no "dead cavity" is left. In cases in which there is tension on the part, the most useful stitch is a combination of a mattress with a simple surgical stitch. A continuous catgut stitch is used to complete the coaptation of the skin edges. The skin is cleaned and smeared over with Moynihan's cream (a mixture consisting of as much bismuth carbonate and 1:1,000 watery solution of mercuric iodid as will make a thick paste) and a simple dry gauze and wool dressing applied. The dressing is not touched for fourteen days. It is then removed, any discharge is wiped away and Moynihan's cream and another dry dressing are applied. At the second dressing a week later the stitches are removed, and never before.

Of ten cases so treated Phillips finds that seven or eight will have healed practically by first intention, one or two will have gaped a bit at one part, leaving a superficial granulating area, and the tenth—practically always one where there has been loss of tissue and consequent tension on the stitches—will be a failure, at any rate in large part, and will require to be done again, or perhaps skin grafting will be necessary.

7. **Laparotomy for Gunshot Wound.**—In Johnston's case of gunshot wound of the abdomen, with perforations of intestine, which were sutured, diffuse purulent peritonitis occurred as a complication, consequent on rupture of an abscess in the anterior abdominal wall. Treatment by the hypochlorite method was carried out, and resulted in recovery.

13. **Symptoms Following Infection by Schistosomum Mansoni.**—In August and September, 1916, twenty-four patients were admitted to an Australian general hospital in Cairo suffering from some or all of the following symptoms: abdominal pain, enlarged and tender liver and spleen, pyrexia, bronchitis, urticaria and diarrhea. All the patients were Australians, who had not traveled before enlistment. At first it was not clear what was the matter with these men, and blood cultures were made and other investigations were carried out with negative results, but the blood picture afforded the key. In every case a striking eosinophilia (5-55 per cent.) was present. This led to prolonged examination of the stools for parasites, and resulted in the discovery of the lateral spined ova of *Schistosomum mansoni.* The ova were found ultimately in the stools of all. The ova were scarce at this stage of the disease, as presumably the majority of the paired adult worms had not yet found a suitable home in the veins draining the rectum. All of these patients had been in camp at Tel-el-Kebir during the three months preceding the onset of symptoms, and it was there, Lawton says, that the infection apparently was contracted.

26. **Surgery of the Heart.**—Delorme has compiled seventeen cases of projectiles in the heart, and states that the missile was removed in thirteen cases, with recovery in all but three. The list includes the successful removal of a projectile in the right ventricle. The operation for removal of a projectile in the heart proceeds very simply, with no sensational features. The injuries discussed might all have been avoided, probably, if a steel breastplate had been worn. The field of intervention on the heart is discussed with much detail, full summaries of a number of cases of gunshot wounds of the heart being given, and the indications according to the parts of the heart involved. He expresses surprise that, from the records to date, no attempts seem to have been made to suture the heart, but projectiles are being extracted with almost constant success.

29. ***Filiform Drainage in Pleurisy.***—Chaput calls attention to the prompt and permanent benefit from filiform drainage in the three cases of pleurisy he reports in detail. This brings to five his total cases of severe purulent pleurisy, including two with gangrene, in which, as he says, without general anesthesia or resection of a rib, the patients were promptly cured by this simple technic.

30. **Different Types of Meningococci.**—Nicolle and his co-workers tested 105 specimens of meningococci of different origins for their agglutination response to monovalent immune serums from the horse and to normal horse serum. The responses classed the meningococci as belonging to four types. Type A seems to correspond to Gordon's Types I and III and Ellis' Types I and II. Type B corresponds to Gordon's Types II and IV. The Type A seems to be identical with Dopter's meningococcus. The findings reported confirm the importance of using both A and B in preparing the immune serum, or else mixing the two antiserums. They also suggest the necessity for determining in each epidemic which is the prevailing type and using a corresponding antiserum.

Netter's experience with serotherapy in 323 cases of meningitis since 1908 confirms the reliability of the agglutination test for classifying the type of meningococci involved in each individual case. He found the B type in his last four cases of meningitis accompanied with purpura, and also in a case of meningococcus septicemia preceding the meningitis by several weeks. In three recent cases from which the B meningococcus was cultivated, rapid recovery followed B antiserum in the two cases in which it was available, in marked contrast to the course in the other case.

31. **Differentiation of Diphtheria and Pseudodiphtheria Bacilli.**—Stévenin reports that in his research the fermentation of sugar and the growth without oxygen plainly differentiated the true diphtheria from the pseudodiphtheria germs. These biologic reactions seem to be constant.

32. **Tin in Treatment of Furunculosis.**—Bruhl and Michaux relate experiences with intramuscular injections of colloidal tin which confirm the view that in this we have another weapon at our disposal in treatment of furunculosis, but that it is not invariably successful.

33. **Exophthalmic Goiter in Soldiers.**—During the last six months, Merklen has encountered about ten cases of exophthalmic goiter in men sent back from the trenches on that account. Other hospitals have reported a similar increase of cases of exophthalmic goiter in men although the total number is small. It usually came on suddenly as is the rule when it is of emotional origin.

35. **Suprarenal Dyspepsia.**—Summarized page 947.

36. **Myotonic Reaction with Tuberculosis.**—Summarized page 1205.

37. **Obsidional Infections.**—Sacquépée gave the name obsidional or siege bacteria to a group of bacteria he found in men who have been for some time in the trenches. The most important of the affections induced by these bacteria is a febrile state with anemia but no eruption and no typhoid state. There is often jaundice and a meningeal condition without appreciable changes in the fluid. In the few necropsies that have been made the liver showed evidences of infection and the spleen was hypertrophied and the kidneys were tumefied and yellow, but the main lesions were hemorrhagic patches and small ulcerations in the bowel, predominantly in the ileum and cecum, with swollen mesenteric glands. No other specific bacteria could be found and there was deviation of complement with the obsidional bacterium discovered. These were the exclusive findings also in a fatal case of choleriform enteritis, and animals inoculated with the bacteria developed similar intestinal lesions.

38. **Icterohemorrhagic Spirochetosis.** — Valassopoulo discusses his experience with infective febrile jaundice at Alexandria, analyzing 300 hospital cases with 32 per cent. mortality, nearly all with necropsy. Since Alexandria and Smyrna have been sewered and the sewer rats poisoned off, the disease has ceased to be endemic at these points. He never observed a case in a child and only very rarely in women, and never a case of direct contact from man to man. The rat seems to be the indispensable intermediary. In some of the epidemics the mortality was 50 or 60 per cent. He gave extract of liver subcutaneously, and when the kidneys were seriously involved he obtained relief with wet cupping or venesection. Isolation and serotherapy promise still better results now.

39 *To Facilitate Search for Helminths in the Stools. J. Carles and E. Barthélemy.—p. 195.
40 Treatment of Traumatic Dislocation of the Patella. A. Charrier and H. Fontaine.—p. 199.
41 *Sunlight in Treatment of Wounds. D. Frèche.—p. 205.

39. **Enrichment Method in Examining Feces for Parasitism.**—Carles and Barthélemy discuss the shortcomings of the different methods in vogue for detecting helminths, their encysted forms and ova in stools. They declare it is necessary to fluidify and homogenize the specimen of stool and bring it to the exact specific gravity most effectual for centrifuging out the parasites and their ova. They get rid of the coarser elements by passing the material through a wire sieve and a silk sieve (Hall). They take 20 gm. of feces to begin with, and dilute with physiologic salt solution containing 10 per cent. formol. The silk sieve has 90 threads to the centimeter (No. 90), except when seeking for ova; these require No. 32. The sieved fluid is then distributed in the centrifuge vials and centrifuged at 1,800 turns for one minute. The supernatant fluid is decanted and the sediment treated with a mixture of 12 gm. citric acid and 2 gm. of a 40 per cent. solution of formol and 86 gm. of water. The specific gravity of this is 1.047. Then 1 or 2 c.c. of ether is added and the tube agitated briskly to detach the sediment. Then centrifuge for thirty seconds at 1,800 revolutions. Then *stir up the zone separating the ether from the fluid, using* the tip of a pipet closed in the flume. This is to restore any cysts that might have been carried up by the ether. Then centrifuge again for thirty seconds as before, and decant all but the sediment. By this technic there is nothing left in the sediment except the helminths, encysted forms of protozoa, ova, and a little other debris of high specific gravity. The specimen is then ready for the microscope and gives exceptionally clean and clear microphotographs, as they illustrate by a few examples showing the lamblia and the encysted forms, with only a few vegetable cells, in one of the four microphotographs.

41. **Sunlight Disappointing in Treatment of Wounds.** — Frèche quotes experiences which demonstrate that the bactericidal power of sunlight is very small in a moist medium. Hence wounds do not benefit from exposure to sunlight as they are not dry and as the blood in the tissues absorbs the more useful rays. While sunlight may kill dry anthrax spores in from twenty-nine to fifty-four hours, this takes very much longer when the spores are sheltered from the air or kept moist. His experience has been less favorable with wounds treated by exposure to sunlight than with other methods of treatment. The only wounds that seemed to benefit were of the torpid type, with smooth, pale pink tissues and no tendency to granulations. But even in these cases, other physical or chemical stimulants gave equally good results.

48 *Periarterial Sympathectomy for Posttraumatic Reflex Nervous Disturbances. R. Leriche and J. Heitz.—p. 754.

42. **War Wounds of Vessels.**—Grégoire and Mondat relate some typical instances of tardy hemorrhage and tardy opening of the artery after a vessel had been injured by a projectile. Among their eighty cases of severe wounds of a vessel, in twenty-four there were no signs of hemorrhage nor hematoma nor ischemia, and only eleven presented immediate and persisting hemorrhage. At their ambulance it was the routine practice to ligate the vessel above and below the injured area, on sound segments. The skin was never sutured at once unless they were sure there was nothing to cause

concern, as gangrene is always imminent after a gunshot wound of a vessel. All the men recovered except two who succumbed to tetanus or gas gangrene, and four others with fatal secondary hemorrhage or anemia.

43. **Immediate Treatment of War Wounds of Vessels.**—In Sencert's experience with forty-two operative cases of hematoma, intense pain and impotence of the limb almost invariably accompanied the wound of the artery, along with more or less shock. Cases of supposed fracture of the femur with complete inability to use the leg sometimes proved to be the result of severing of the popliteal vein, the bones intact. The complete impotence of the limb and the pain may be in striking contrast to the visible injury of the soft parts. The injury of the vessel sheath and its sympathetic plexus likewise explain the tendency to shock. The vessel should never be ligated if suture is possible, but every hematoma should be evacuated at once. He gives an illustrated description of the best mode of access to the trunk vessels of the axilla, base of the neck, and elsewhere. By lifting up the main artery on a stout catgut it is kinked and the blood stream arrested. This has another advantage over a ligature as by lowering the catgut the blood flows again and the lesion in the artery is thus accurately located. He has found this method of hemostasis work well on the common carotid, external iliac and other arteries. Even at the best, diffuse hematomas are dangerous; fully a third of those involving important arteries treated by ligation in the wound developed partial or total necrobiosis below.

44. **War Wounds of Vessels Without External Hemorrhage.**—Alamartine reports thirty-two operative cases of aneurysm or arteriovenous fistulas, and discusses the various minor symptoms.

47. **War Wound in a Hemophiliac.**—The young man, his brother, his mother and her brother were all bleeders. He had had three severe experiences with persisting hemorrhage at different times, but the bleeding had always stopped spontaneously about the twelfth day, regardless of the measures applied. Wounded in the hand, sheet hemorrhage kept up for the usual twelve days and then stopped, but the anemia was fulminating and extreme. The blood recuperated, however, as rapidly as the anemia had developed. The whole arsenal of measures to combat hemophilia had been applied but none seemed to do any good, except strong compression with the limb raised. The minute details of analysis of the blood at intervals show that there was no lack of fibrinogen or calcium salts. Neither horse serum nor beef serum accelerated coagulation, which demonstrates that these serums do not supply a lacking thrombozym but act as antigens, inducing an organic reaction. Fresh human serum shortened the interval before coagulation but this effect was still more marked with white corpuscles from normal human blood. When washed white corpuscles were added to the hemophiliac blood, coagulation occurred rapidly. This seemed to show that the white corpuscles supplied the element which was lacking in the hemophiliac blood. It is possible to obtain a leukocyte clot which might aid in arresting a hemophiliac hemorrhage applied directly to the bleeding spot. Draw 5 or 10 c.c. of venous blood into twice its volume of one third alcohol (*alcool au tiers*). Agitate. Centrifuge immediately and decant the hemolyzed fluid. The clot of leukocytes left can then be applied directly to the bleeding surface. This seems to be unquestionably the best local method for promoting local coagulation.

58 Attacks of Amebic Dysentery in Carrier after Antityphoid Vaccination. Bouyer.—p. 255.

49. **Overlooked Form of Pulmonary Syphilis.**—Leredde reports positive responses to serologic and clinical tests for syphilis in many cases of recurring bronchitis, emphysema and asthma in young men and women. He reports the details of twenty such cases. All had been inclined since childhood to shortness of breath on exertion, and several had emphysema. Some had attacks of asthma, and all had certain or probable inherited syphilis. There seems to be some underlying active process of sclerosis. Tests for syphilis should be made in all cases of asthma, emphysema, dyspnea on effort, and recurring bronchitis at any age.

50. **Operative Treatment of Inguinal Hernia.**—Soubeyran gives an illustrated description of what he calls the antefunicular procedure for strengthening the wall in correction of inguinal hernia. Its chief advantage over the Bassini is that the cord is not drawn to one side and thus subjected to possible injury, but is pushed down into the plane of the subperitoneal cellular tissue in contact with the peritoneum.

53. **Venereal Diseases.**—Gougerot reiterates that every means of reducing the spread of venereal disease should be intensified and applied simultaneously. He describes the model, entirely gratuitous, "annex service" to seek out and cure the contagious cases, and thus suppress the source, and he insists that every city, every important garrison and agglomeration of working people, every place large enough to have a prefect or subprefect should have this annex service. Its chief should be in close touch with the prefect, and the service should work along the five main lines: education of the public, and detection and treatment of venereal diseases—the dispensary open to men and women outside of working hours; surveillance and treatment of prostitutes with dispensary and hospital care apart from the quarters for the nonprostitutes; search for and treatment of foci of contagion. He has organized eleven annex services of this kind in his district. The chief of the annex service should be an expert in dermatology, urology and practical gynecology besides venereology. The personnel should include a bacteriologist, a dentist, and one or two men or women nurses trained specially for the service. The annex service should organize substations throughout the district not restricting its action to the towns. For this he suggests flying dispensaries, *consultations ambulantes.* The chief or his assistant takes in an automobile the necessary equipment for examination and treatment, and gets the proprietor of a large factory to lend him the use of a room at a convenient hour, or he gets some room nearby. He may thus be able to attend to several large industrial establishments in a day. Gougerot has found this plan work finely in the district in his charge. Otherwise he has to depend on the factory physician to sift out and send to the central service those needing attention. Free railway return tickets are given out by the mayor for this purpose. Gougerot discusses further the difficulties and obstacles presented by organization of the annex services, and by the objections and inertia of the existing town and hospital authorities, and how to overcome them. It will require legislation for central organization of the service, and placing the surveillance of prostitutes in the hands of the chief of the service. In conclusion Gougerot reviews the vast field of prophylaxis, urging especially financial inducements for earlier marriages, and the conferring of the rights of a legal wife on a girl that has been deflowered. He also urges the need for recreation centers for the young, and canteens, particularly in the railroad stations for soldiers passing through. Intensify, organize and unify, and above all, be quick about it, is his cry.

54. **Motor Reeducation.**—Sollier declares that mechan apparatus do actual harm in treatment of functional tence of nervous origin, actually increasing the tro many cases, both physiologically and psychologic

the other hand, all the elements are favorable for a cure when the reeducation is along the lines of work to which the patient was formerly accustomed. As movements return, the rehabilitation is both physical and moral. In the "neurologic center" in his charge, thirty months' experience has confirmed the advantages of farm and gardening work and woodworking in rehabilitating the wounded both in body and spirits.

56. **Resuscitation of the Heart by Stimulating the Accelerator Nerves.**—Morat and Petzetakis give some electrocardiograms showing that after the heart action in animals had been arrested for over twenty minutes, it could be started to working anew by applying a medium electric current to the accelerators or even to one alone. The experiments were made with animals under the influence of chloroform and extreme cold. One tracing shows how the electric stimulus was applied to the right sympathetic just above the first thoracic ganglion. All the cavities of the heart had stopped during diastole. Five seconds after the stimulation of the accelerators, the right auricle and almost at once the left auricle also began to contract while the diastole of the ventricle persisted. The auricular contractions, weak at first, gradually became stronger and then suddenly, at about the seventeenth second, the ventricles started up, the rhythm closely like that of the auricles. Two other electrocardiograms show the similar revival of heart action in dogs after ten minutes of arrested heart action.

60. **Peripheral Sympathectomy.**—Leriche relates that in thirty-seven cases he has treated rebellious contracture or causalgia by denudation and excision of the periarterial network of sympathetic fibers. Others have applied the measure also since his first publication on the subject, summarized in these columns April 21, 1917, p. 1216. In this later series the pain was permanently abolished in some but not in all. In five cases of trophic ulceration a complete cure was realized in all. The outcome was a complete success in sixteen of the total thirty-seven cases, and when the peripheral sympathectomy was associated with massage and training of the muscles, good results were obtained in a number of the others. On the whole, peripheral sympathectomy is an interesting and useful operation in severe forms of what are known as "reflex nervous disturbances," pain, paralysis and contracture. The exact indications for it are not quite decided as yet.

61. **Facial Paralysis.**—Pauchet and Labouré describe the measures indicated for medical and for traumatic facial paralysis, and give an illustration of the technic for suture of the nerve in case of fracture of adjacent bones. In twelve operations on the nerves the outcome was excellent in seven. Operations on other nerves, they reiterate, seldom give as good results as anastomosis of the nerves responsible for facial paralysis after a war wound.

62. **Disturbances from Chilling of Hands and Feet.**—Cottet calls attention to the acroparesthesia from the action of cold which is the first symptom of what progresses to frozen feet and hands. He thinks that the importance of chilling as a factor in pathology has been too much overshadowed by the notions of infection. Cold, and especially damp cold, may be an important factor in those states of vague pains ascribed sometimes to rheumatism, sometimes to neurotrophic disturbances. The prompt and remarkable benefit under local heat confirms this assumption. The segments of hypoesthesia *a frigore* may be exactly like those of hysteria. They are symmetrical and sharply defined, and are accompanied by zones of hyperesthesia. The circulatory disturbance under the action of the cold interferes with the nourishment of certain nerve fibers in the region as their blood supply is shut off. The resulting diffuse and superficial neuritis classes this acroparesthesia from chilling with the trophoneurotic vasomotor syndromes.

63. **Treatment of Laryngotracheal Stenosis.**—Jouty gives an illustrated description of his method of dilation through a tracheolaryngostomy. A soft rubber tube in the throat is held in place by a hollow mallet shaped metal tube. A silver plate slipped over the projecting shank holds a small dressing against the opening around the projecting tube, and a nut holds this plate firm. This plate and the projecting nut are all that shows, no other dressings being needed.

66. **Flexion of Big Toe on Percussion of Achilles Tendon.**—Only the terminal phalanx bends, and this occurs when the sciatic nerve is diseased. The reflex cannot be elicited in normal conditions.

67. **Limits of Asystoly.**—Perrin warns that we must not wait for the trio, hypotension, tachycardia and oliguria, before diagnosing insufficiency of the contracting power of the heart. There are atypical forms of it, sometimes with abnormally high blood pressure, sometimes with what seems to be polyuria, but is in reality a relative oliguria compared with the amounts of urine previously voided. The pulse likewise may be abnormally slow, although in comparison with the previous pulse rate it is much accelerated. In one such case the pulse never went above 74 although the temperature ran up to 39.2 C. during the pneumonia which had affected the heart. Under digitalis and good nursing the man recovered, his pulse then declining to its habitual rate of 40. Perrin adds that the atypical forms of asystoly call for the same measures as the typical cases.

71. **Poisoning from Silver Salts.**—Besides four cases of universal argyria following medication with silver salts, Steiger mentions some industrial cases in men or women working with silver. He discusses the literature on the subject and the various clinical pictures induced. In three of the four medicinal cases reported, the universal argyria was pronounced, and nothing seemed to modify it. The total dosage had not been as large as in other cases on record, the patients having taken only from 4 to 6.5 gm. silver nitrate in the course of from one to thirteen years. One tabetic man of 56 had taken 400 pills of 0.01 gm. each in the course of five years; the other patients were women in the forties. In the cases previously published, 20 or 30 gm. had been the amount taken before the argyria developed. In Steiger's fourth case the argyria was restricted to the conjunctiva; the silver nitrate had been applied 100 times to the eye in treatment of trachoma. He urges research on silver poisoning as better understanding of this might throw light on numerous questions as to absorption and elimination. In his cases silver was found in the stools and in some cases in the blood, but never in the urine.

77 *Technic for Exposing the Radial Nerve in the Upper Arm. V. Putti.—p. 403.

73. **Treatment of War Wounds.**—Magn[illegible] injury of the cases such as reach him in the base hospital [illegible]eed into the Sixteen double-line pages of titles of articles on [illegible]ceps are tology of war are appended to his article. His exp[illegible]ty-two with 3,618 cases of war wounds of limbs during an eig[illegible]ny months' period has convinced him that it is best to leave [illegible] wounded limb unmolested as much as possible and keep it quiet. This was preached by Magati as long ago as 1616, so he calls this system of immobilization with rare change of dressings the Magati method. The wound should be cleared out at first but then the dressing may be left untouched for two weeks or more unless special indications arise. The skin irritated by prolonged contact with pus is soothed by painting with paraffin dissolved at 45 C. He did not drain often, believing that this is necessary only when there is danger that an infectious process may be shut in too soon by the superficial tissues. He never injected any drugs into the wound, never aspirated fluid or rinsed out a joint, and resected only in two cases and extracted the projectile in three cases. All the others recovered under immobilization alone, draining merely when there was a pus pocket and not replacing the drain when this was cleared out. Solid plaster casts answered the purpose better than the fenestrated. Massage in case of stiffness and adhesions is more effectual when done under active hyperemia or, better still, under passive stasis. His experience has shown further that the large vessels can be ligated at any point in their course unless there are acute or chronic inflammatory processes in veins, obstructing the venous collateral circulation. In this case gangrene is inevitable.

74. **Sodium Salicylate in Prophylaxis of Sepsis in War Wounds of Joints.**—Impallomeni cites authorities to show that sodium salicylate is eliminated by the synovial membranes. This suggested that it might aid in warding off sepsis in case of a war wound of a joint, as this drug is the sovereign remedy for rheumatic arthritis. The trauma from the war wound evidently aids in attacting the drug to the spot, like an infectious process, and his experience during the war, he says, has brilliantly confirmed the correctness of his premises. A number of typical cases are described and illustrated, all corroborating the value of sodium salicylate for warding off septic processes in the joint. A dose of 0.5 gm. is given by the mouth at the first dressing, when a joint has been wounded, and this treatment is continued later or, better yet, a subcutaneous or intramuscular injection or both are given. The synovia responded positively to the ferric chlorid test for salicylic acid in about four hours after ingestion of 1 gm. of sodium salicylate, and with greater intensity by the sixth hour. The interval was half an hour shorter when the drug had been given subcutaneously or intramuscularly. When the response is negative after the infectious process has been installed for some time, this testifies that the endothelium of the synovial membrane has been extensively destroyed, and this alone may call for prompt surgical intervention to arrest the evidently progressive lesion. The formula found best adapted for subcutaneous or intramuscular injection is a mixture of 1 gm. sodium salicylate; 0.01 gm. stovain; 0.04 gm. sodium chlorid and enough 25 per cent. glycerin-water to make 10 c.c. The vial containing this is heated to 100 C. (212 F.) for twenty minutes.

75. **Scoliosis.**—Serra and Valtancoli write from the Rizzoli Orthopedic Institute at Bologna to analyze the course and outcome of treatment in 483 cases of scoliosis classified according to the clinical and morphologic features of the cases. Over 82 per cent. of the patients were girls, but the severest forms of curvature of the spine were more prevalent in boys. The different varieties of curvature and their proportionate frequency at different ages are shown in various charts.

77. **Exposure of the Radial Nerve.**—Putti expatiates on the advantages of Gosset's technic for direct access to the radial nerve. The arm is placed on a table—an extension of the plane of the bed—the arm slightly abducted and rotated inward, the elbow bent at a right angle and the forearm close to the chest. The incision, about 15 cm. long, slants from above downward and inward, starting about an inch

tones, etc., for which the hearing is most defective, and practices these predominantly. The sittings are for ten to twenty minutes, twice a day, treating each ear separately. Local lesions and constitutional causes must be sought and corrected so far as possible, and it is useless to apply this treatment to the very old or the very young, the congenitally deaf, the stupid and those unwilling or incapable of concentrating their [illegible]ntion on the course of treatment. He insists also on the [illegible] living a sociable life, listening and talking, not

79. **Prophylactic Tuberculin Treatment.**—Bertarelli relates that he experimented with tuberculin on himself, and found that the deviation of complement test elicited a positive reaction in a few weeks after he had begun to give himself a weekly injection of minute amounts of old tuberculin. By the end of a year he had reached the dose of 1 c.c., and now, three years after the last injection the deviation of complement test is still strongly positive. Theoretically, a prophylactic course of tuberculin would seem justified in families exposed to special danger of infection, and he urges others with more opportunity to try it.

Riforma Medica, Naples

September 8, XXXIII, No. 36, pp. 869-892

85 *Rheumatic Purpura with Certain Features Suggesting Scurvy. U. Gabbi.—p. 869.

85. **Scorbutiform Purpura in the Troops on Active Service.**—Gabbi comments on the remarkable healthiness of the troops exposed to the cold of the firing line among the mountains. Although so many of the men come from the warm south of Italy and the islands, they seem to thrive among the snows of the mountains. But when there is any morbidity it is usually of a hemorrhagic type. He describes here in particular a rheumatic purpura, with features suggesting scurvy, which is either a new morbid entity or an old one with so many new characteristics that it assumes a new clinical physiognomy. The details of nineteen cases are given in full with some illustrations. The men had very rarely eaten canned meat. Mild and severe cases were encountered grouped together, but the whole trouble was benign and comparatively brief, free from complications or sequels, and except in a few cases there was no bowel trouble. There was always more or less fever and enlargement of the spleen, with slight albuminuria and sometimes hemorrhagic nephritis. No benefit followed the change to food which cures scurvy. Another peculiar feature of the cases was that they developed in spring and summer and the winter was practically free from cases. Sometimes a mild case was apparently subsiding when it flared up suddenly into a severe form with symptoms suggesting scurvy. Gum lesions were present even in certain mild cases and were absent in some of the gravest cases. A long question blank was sent to the various hospitals asking for the special features of this disease that had been n[illegible]

the other hand, all the elements are favorable for a cure when the reeducation is along the lines of work to which the patient was formerly accustomed. As movements return, the rehabilitation is both physical and moral. In the "neurologic center" in his charge, thirty months' experience has confirmed the advantages of farm and gardening work and woodworking in rehabilitating the wounded both in body and spirits.

56. **Resuscitation of the Heart by Stimulating the** -por- uggests
tor Nerves.—Morat and Petzetakis give some el portance of
grams showing that after the heart action is always a
been arrested for over twenty minutes, it fth lassitude and
working anew by applying a medium onset of the fever in

tricle p and G. Ollino.—p. 357.
grad le War Neuroses. G. Barbensi.—p. 360. Continuation.

57. **Autogenous Vaccines in Treatment of War Wounds.**—Stradiotti and Ollino prepared the vaccine with the various germs found in the wound, and made a point of applying it at once or at latest at the second dressing. One or more loops of the pus were transferred to bouillon and the vaccine was sterilized by addition of chloroform to the culture medium, agitating it at intervals for two or three hours. After this it was always found sterile. In their hundreds of applications of these vaccines they never had an abscess or serious general reaction; at most there was a transient redness at the point of injection. They began with 1 c.c. of the bouillon culture, increasing the amount by 1 c.c. at each injection, at intervals of from three to six days; the larger the dose the longer the interval. The maximal dose reached in any case was 7.5 c.c., and this was borne perfectly. It is better to make fresh vaccine from time to time, and not use any one too long. The principle is rational, the procedure harmless, and the general impression of the results most favorable. The outcome was better the earlier the vaccine could be given but a beneficial influence was apparent often in cases of advanced infection if the general symptoms were not the expression of septicemic generalization of the infectious process. Even in such cases the fever frequently declined after the injection and did not go up again until several days later, when it could be again brought down by repeating the injection. The vaccine therapy is not adapted for very grave cases of inveterate suppuration in knee or thigh, such extensive lesions not being easily stimulated to defensive reactions. They have been applying this vaccine therapy for about a year, and usually are able to make the injection within forty-eight hours of the wound, but the technic used makes no provision for anaerobes. They apply the autogenous vaccines also in treatment of furunculosis and other superficial suppurating processes, and report further complete success in a small epidemic of erysipelas which was arrested by prophylactic injection of a vaccine prepared from one of the sick, thus protecting the forty other inmates in the surgical ward. These preventive doses were 1, 2 and 3 c.c., at three or four day intervals.

89. **Hodgkin's Disease.**—Dias announces that his research has apparently demonstrated that the causal agent of Hodgkin's disease is a remarkably polymorphous fungus. It locates in lymph glands and can be cultivated from them, and
heat confirms animals. His communication was presented
esthesia a -an Society of Tropical Medicine although this
They a by no means confined to the tropics, but it happens
panic articularly prevalent in the state of Minas Geraes in
zil, and special studies were made of it in the local branch
there of the Instituto Oswaldo Cruz with which he is connected. This research demonstrated that the disease was the classical Hodgkin's disease which was doubted at first, the possibility of a new morbid entity having been considered and the name "adenomycosis" suggested for it. Cultivation on Sabouraud's saccharosed gelose succeeded in about 50 per cent. of the inoculations, the growth with one type of the germ resembling that of cultures from actinomycosis. The other principal type is more bacilliform in aspect and cultures. These differences are more marked at first than later, in time all the cultures resembling each other. The rat, guinea-pig, rabbit and monkeys are susceptible to the germ, and all die sooner or later when inoculated in the peritoneum, although the experimental disease may last for a month or more. Until it is possible to classify the germ correctly, he has given it the provisional name of the *Adenomyces cruzi*. He thinks that leukemia may yet be proved to be a mycosis.

90. **Acute Pyelitis in Children.**—De Rezende describes a case to illustrate a common mode of onset of acute pyelitis in children in Brazil, recurring abrupt attacks of high fever preceded by a chill and followed by sweating, suggesting acute malaria or the fever of septicemia or suppuration. The urine of the nine months' babe contained extraordinarily large amounts of albumin, clearing up the diagnosis at once. In some cases the fever is continuous or subcontinuous as in typhoid, or it may be frankly remittent, or there may be slight chronic fever. In short, whatever the type of fever, in an infant or child, and whatever its duration, examination of the urine should be a routine measure to exclude pyelitis as almost the first step. He has found the colon bacillus usually responsible, and notes that pyelitis attacks girls more than boys. These facts suggest prophylactic measures. In treatment, the aim should be to render the urine alkaline and keep this up until all symptoms have disappeared. His experience with pyelitis in children has fully confirmed Thompson and Hutchison's assertions in regard to the almost specific action of large doses of potassium citrate. This does not act on the bacilli, however, and after cessation of the alkali treatment de Rezende suggests that it might be well to follow with hexamethylenamin. The two should never be given together. For adults, he gives a solution of acid sodium phosphate, 10 gm. in 300 gm. cinnamon water. The dose is a tablespoonful in half a glass of sweetened water every four hours. The hexamethylenamin is given two hours later.

95. **Treatment of Rupture of the Uterus During Delivery.**—Mazzini reports five cases of rupture during delivery which he treated by drawing down with his hand the upper lip of the rupture inside and well past the lower lip, then keeping up the traction on the upper lip by substituting long forceps for the hand with which he was holding it. The lower portion of the uterus was then packed with gauze around the forceps, distending it well, and then the vagina. He uses two forceps or more if needed to draw the upper lip of the rupture well down all around, and leaves a drain tube.

The tamponing all around them prevents any injury of the walls. A retention catheter is then introduced *into the* bladder, and the projecting handles of the forceps are wrapped in gauze. He removes the tampon after seventy-two hours and also the drain tube and forceps, but avoids any exploratory measures; merely giving an antiseptic vaginal douche under weak pressure. The treatment after this is as for any parturient. This technic when introduced by Boero was supposed to be applicable only to spontaneous rupture, but Mazzini's five cases testify to its suitability for traumatic rupture whenever the cervix is open enough for the hand to be introduced to grasp the upper lip of the tear. In his experience the promptly and permanently favorable results in 80 per cent. of the cases surpass even Boero's 75 per cent. of cures in his twenty cases since he published this technic in 1910. In Mazzini's first case the uterus had ruptured at two points, and he sutured the longitudinal tear and treated the transverse tear as described above. The woman recovered without sequels, and all seemed to be normal a year later. In the one case in which fatal peritonitis developed, this was the ninth pregnancy. Six had terminated normally and this one seemed to be proceeding regularly at first and until the rupture. The placenta had to be removed by hand, as it had caught in the rupture opening. The front of the entire segment had been torn off and, notwithstanding the Boero procedure, peritonitis developed and proved fatal the sixth day. The fetus died about *the time of the rupture* in each case. The rupture occurred in the maternity in all but the first case.

97. **Tuberculosis in Argentina.**—Coni mentions that Argentina was the first country in Latin-America to include pulmonary tuberculosis among the diseases requiring compulsory notification. He reviews the history of tuberculosis in Argentina and of what has been done to arrest its spread. Fully 85.6 per cent. of the general mortality in 1913 throughout Argentina was due to tuberculosis. He sustains those who plead for preventoriums, farm colonies and similar inexpensive and accessible institutions for caring for the tuberculous instead of, at first, expending much money on mountain and seashore sanatoriums. The Buenos Aires hospitals turn away every day, it is said, up to twenty or thirty applicants with pulmonary tuberculosis for whom no beds can be found.

98. **Normal Beef Serum in Treatment of Anthrax.**—Solari reports that his trials of normal beef serum in treatment of anthrax have confirmed in every respect the statements of Kraus and Penna as to its efficacy. The results, *he says*, could not have been more satisfactory. It is evident that normal beef serum, heated twice for half an hour to 56 C., does not induce any injurious reaction when injected into man. He gave it subcutaneously in doses of from 10 to 30 c.c. in the twenty-four hours as a rule, sometimes giving more, up to a maximum of 60 c.c. The benefit was as prompt and as *marked* as with the prepared *immune serum he had been* previously using. The case history and chart from each of his six cases are reproduced.

105. **Reeducation of the Hearing.**—Compaired expatiates on the advantages of the Zund-Burguet or similar apparatus for aiding in saving the hearing and *improving* it. He asserts that the improvement realized with this apparatus, which he has been using for six years, surpasses all that can be attained by *other means*, especially in the cases of deafness from otosclerosis and adhesive otitis. He seeks out the tones, etc., for which the hearing is most defective, and *practices these predominantly*. The sittings are for ten to twenty minutes, twice a day, treating each ear separately. Local lesions and constitutional causes must be sought and corrected so far as possible, and it is useless to apply this treatment to the very old or the very young, the congenitally deaf, the stupid and those unwilling or incapable of concentrating their attention on the course of treatment. He insists also on the patient's living a sociable life, listening and talking, not spending his time reading or in solitude but keeping up exercises of the hearing, listening to music and to reading aloud. If no benefit has been realized in the first thirty sittings, given twice daily, for five or ten minutes, there is no use in keeping them up longer. With very sensitive persons it may be better to have only one sitting a day or at longer intervals. The treatment has never done harm in any instance; if it does not improve, at least it never aggravates the condition.

107. **Acute Nephritis and Renal Organotherapy.**—A robust young man in the second or third week of an attack of influenza suddenly developed pulmonary edema, and palpation revealed that the right kidney and ureter were extremely tender and the left slightly so. The symptoms of acute *nephritis* became more and more threatening, with a tendency to coma by the end of the week. He was then given a subcutaneous injection of 10 c.c. of serum from the renal vein of the goat, and when hope had almost been lost, seventeen hours after the injection, copious diuresis set in and the alarming symptoms subsided. The injection was repeated the next day at the same hour and the organotherapy continued after this with kidney extract. This was suspended after three days on account of the expense, and the next day there was another attack of pulmonary edema but not so severe as the first. As recovery progressed there were occasional attacks of dyspnea even after the kidney functioning seemed to have been restored to normal. Gil ascribed the dyspnea to toxic weakness of the heart, and this assumption was *confirmed* by the *prompt* efficacy of caffein citrate, each time, given by the mouth or subcutaneously.

109 Primary Malaria in Macedonia. P. Abrami.—p. 17.
110 *Serotherapy of Malaria. Sotiriades.—p. 27.

108. **Masked Dysentery.**—Cecikas' experience has been that agglutination is not distinct enough as a rule to distinguish between *the different* species of bacilli responsible for bacillary dysentery. Biologic diagnosis, however, permits correct serotherapy, and in two cases reported in detail this proved successful after years of futile other treatments. One man of 30 had a *history of tropical enteritis seven years before*, treated with emetin later and various courses at spas, but the enteritis was liable to return every summer. There were also *attacks of tachycardia and joint trouble*, and the lower part of the left abdomen was tender. No amebas and no colonies of colon bacilli developed on the Drigalski medium but nonmotile bacilli proliferated that agglutinated the Kruse bacillus, and under Kruse-Shiga serum the chronic tendency to enteritis was permanently cured. By the eighteenth day no suspicious colonies developed while the colon bacillus flourished abundantly. This primary absence of the colon bacillus he regards as significant as also its reappearance as the man regained complete health. Cecikas remarks that with all the varying diagnoses and treatment during the seven years in this case, "the patient had stuck to enteritic diet, used aperient salts and took castor oil nearly every week, this regular life and diet explaining the complete *restitutio ad integrum* which undoubtedly followed the weakening of the dysenteric bacilli by the serotherapy and their final disappearance." This assumption of the superficial nature of the alterations caused in the bowel mucosa by the prolonged presence of the germs is sustained by another case of undiagnosed bacillary dysentery with dyspnea, palpitations, and polyuria, especially at night. The primary enteritis

dated from twenty-nine years before. Under the serotherapy complete health was speedily regained. In another case the chronic dysentery was regarded as enteritis mucosa and treated without benefit, but prompt recovery followed the serum treatment. The fourth patient was a woman of 28; the dysentery had commenced insidiously three years before and the symptoms had been ascribed at one time to metritis and a gynecologic operation had been done without relief. The rectal mucosa had ulcerated.

In young children and babies the bacillary dysentery may develop in an acute form. In one out of several such cases in his practice, the infant developed menacing "enteritis" two weeks after the father had been under treatment for frank bacillary dysentery. Without waiting for bacteriologic confirmation, Cecikas gave the collapsed infant the same serotherapy, and the child soon recovered. Cultivation of the stool taken at the first visit showed the Kruse Shiga bacillus agglutinating at 1:500. There are no distinguishing features in the early stage of acute bacillary dysentery in children, but the case as a whole may suggest by the second or third day to use the serum "which finally can do no harm. It is a golden rule to proceed in intestinal troubles at the first visit to bacteriologic examination of vomit and feces."

110. **Serotherapy of Malaria.**—Sotiriades reports that he injected serum from one patient with malaria into a second patient who had just contracted malaria. There was no further fever for four days then came a much milder attack and the plasmodium was found in the blood as at the first attack. A second subcutaneous injection of 10 c.c. of the serum from the first patient was made and the next day, during the interval a third injection was made. The second patient had no further fever during the twelve days he was under observation. The donor had the parasites still in the blood at the time but the spleen was not enlarged and he had had no attacks of chill or fever for some months.

115 Vaccination against Typhoid. P. N. Triudin.—p. 373. Conclusion. A. O. Fraifeld.—p. 377.

111. **Palliative Treatment of Inoperable Rectal Cancer.**—Fedoroff comments on the difficulty of keeping fecal matters and fluids out of the lower segment of the rectum when an artificial anus has been made above. With the technic he describes, however, this can surely be accomplished, and the lower segment left in peace as completely as if it had been cut across, while the procedure is simple and harmless. He makes a slanting incision in the abdominal wall, about 10 or 12 cm. long, in the left iliac region, from 1½ to 2 fingerbreadths from the outer edge of the rectus muscle, and draws out through it the adjacent portion of the sigmoid flexure. Then he loosens up and cuts a strip from the aponeurosis of the external oblique muscle the whole length of the inner margin of the incision. This strip of aponeurosis is left connected with its aponeurosis bed only at the lower angle of the incision. Then this strip is passed through a button hole in the mesentery of the bowel, close to the latter. The strip is then passed around the bowel two or three times and drawn tight. The free end of the strip of aponeurosis is then sutured firmly to the opposite edge of the incision, and the bowel above is sutured to the lips of the incision. Then, according to circumstances; from two to five days later, an opening is made into the bowel above the ligature. By this means the lower portion of the rectum is shut off so that neither fluid nor solid matters can work their way into it, and the patient is spared all irritation and pain from this source.

112. **Differential Diagnosis of Heart Disease.**—Mintz' conclusions are based on examination of hundreds of men suspected of heart disease. He remarks in the first place that men with stomach trouble are liable to ascribe their disturbances to the chest or heart rather than to the stomach. In only 20 per cent. of 135 with these complaints were the stomach findings normal; in 33 per cent. there was hyperacidity, in 14 per cent. anacidity, and motor insufficiency in 18 per cent. In the majority of the men free from organic heart disease, the nervous excitement from the examination increased the pulse rate and also the blood pressure, while in those with fully compensated heart defects and in many with acute infectious disease of the heart, the pulse did not grow faster, and the blood pressure persisted normal or dropped below normal. The heart seems to have to work harder when the person reclines than when he stands. This is evidenced by the louder systolic murmur, the passage of the prediastolic murmur into the systolic, and the accentuation of the second sound of the pulmonary artery when a patient with mitral defect reclines. The accentuation of the second sound manifest in the reclining position may be one of the very earliest signs of true heart trouble. The percussion findings as to the proportions of the heart are often normal even with a valvular defect.

In consequence of the variability of the left nipple line, we must be extremely cautious in affirming an increase in the size of the heart. The distance between the left nipple and the median line ranged from 8 to 12 cm. in his cases. The distance from the left nipple to the tip of the apex may reach 3.5 cm. No parallelism between the size of the heart and these differences in the location of the left nipple could be detected as a rule. In the mild and beginning cases of mitral defect, the systolic murmur is heard exclusively over the pulmonary artery. A loud systolic murmur keeping strictly to the pulmonary artery is of accidental origin, and may be encountered with tachycardia. With tachycardia, the first sound a sharp clapping, the blood pressure is abnormally high. When the first sound is the normal tone, the blood pressure is normal in the majority of cases; with embryocardia, it is below normal. A brief systolic murmur is often noted with tachycardia. The systolic murmur of organic origin keeps much fainter, and it may disappear altogether in the reclining position. With palpitation of the heart, a murmur is sometimes heard at the apex for which a reflux jet of blood from the ventricle into the auricle may be responsible. The question as to the reserve energy of the well hypertrophied heart and the power of adaptation to increased demands, is still open to discussion. According to his personal observation, the heart even with a well compensated defect responds differently to excitation (pulse rate, blood pressure), from the sound heart. If we consider the accentuation of the second pulmonary sound with overburdening of the heart (the *Belastungsprobe* of the Germans), an index of its functional capacity, then we must arrive at the conclusion that the reserve force of the heart, even with perfect compensation, is limited and small. Accepting the above, it follows as a matter of course that men with even slight heart defects cannot be utilized for military service.

Hospitalstidende, Copenhagen

August 29, LX, No. 35, pp. 837-860

116 *Joint Lesions with Syringomyelia. V. Askgaard.—p. 837.
117 Synovial Cyst—Arthroma—in a Muscle. A. Sennels.—p. 846.

116. **Joint Lesions with Syringomyelia.**—Askgaard remarks that joint lesions are the rule in about 25 per cent. of all cases of syringomyelia, and describes with illustrations an exceptionally severe case in a man of 39. The wrists and hands were the seat of the destructive and deforming process but, as usual, there was little tendency to ankylosis. As spontaneous remissions sometimes occur, treatment should be conservative unless the disturbances demand resection. When this is the case, as recurrence is liable, amputation is better than resection. Ample facilities for drainage should be provided, but even large accumulations are sometimes spontaneously absorbed. This occurred in one hand in the case reported, and the other is being treated conservatively. The wrist is worn in a sling. The fingers can still be used actively but those on the other hand were left contracted. Amputation has been considered, but the fear of recurrence in the stump weighs down the scale against it.
